4831.—Roses pegged down.—Should Roses which were pegged down in the spring be tied up during the winter, or protected in any way?—B. P.

4832.—Lemon Verhena.—What is the right time of the year to plant Lemon Verhena out-of-doors, and where can good plants be obtained? Locality, Dorsetshire.—B. P.

4833.—Paint for fruit-trees.—Will anyone tell me what are the ingredients used for painting over the stem of fruit-trees? I know parisian is one of them.—JANE GOLLEY.

4834.—Book wanted.—I should be much obliged if anyone could inform me where I can obtain a copy of Mr. Dorian-Smith's pamphlet on gardening in the Solly Isles?—C. F. WALKER.

4835.—Begonia seed pods.—Would someone kindly tell me the best way of drying Begonia seed-pods, as I get very little sun in my greenhouse, and have some splendid pods I wish to ripen?—ROSEWILL.

4836.—Planting Poplars.—Will anyone kindly tell me how to plant Poplars to form a hedge 6 feet high, and whether to begin now? The situation is near the sea, and the soil is cold, heavy, sandy loam.—W. E. H.

4837.—Hardy fruits.—Will anyone kindly tell me the hardest kinds of fruit of all kinds for an orchard to grow in a very bleak place, and how to treat them? Soil, very stiff loam, clay bottom. Locality, West Derby.—E. J. H.

4838.—Carrots for show.—What are the best varieties of Carrots for exhibition, and when should the seed be planted to see them fit for getting by the end of July? A few hints how to grow them will be gladly received.—LEARNER.

4839.—Treatment of White Pearl Tuberoses.—Will anyone kindly tell me the proper treatment for White Pearl Tuberoses? I have a little stock heated with fire, which I can keep at about 40 degs. in winter. Would this do?—W. D.

4840.—Treatment of Roses.—My Roses have made enormous shoots since July, but there have been no blooms, and the first blooming was very poor, in spite of constant watering. Directions as to present and future treatment will oblige.—M. L. E.

4841.—Standard Roses.—Will anyone kindly tell me which are the best kinds of bush or standard Roses for growing in a very bleak place? I want them free and strong. Soil stiff, and clay bottom. How should I treat them? Locality, West Derby.—E. J. H.

4842.—Early Peas under glass.—Will someone kindly tell me if I could grow Peas to perfection in the border of a Tomato-house? When would they come into bearing? I sowed the first in December? Also what sort would be most suitable?—AMATEUR, Devon.

4843.—Onions for show.—I shall be greatly obliged if someone will give me the names of the best Onions for show purposes, globe and flat varieties, and what time should the seed be sown to get them ready for showing in August, and how should they be grown?—LEARNER.

4844.—"Canker" in Apple and Pear-trees.—I am anxious to know how to prevent "canker" in Apple and Pear-trees. Several in our garden are much injured by these lumpy excrescences on the branches and twigs, which almost kill the bearing shoots and prevent fruiting.—BIRRA.

4845.—Treatment of "Geraniums."—I have some "Geraniums" grown from seeds sown last spring. They are now in 5-inch pots, but do not show any sign of blooming, and seem to make little progress. How ought they to be treated, and when should they bloom?—M. L. E.

4846.—Transplanting Laburnums.—I should be glad to know the proper time to transplant young Laburnum-trees which have grown in my garden from seed taken from the old trees; also kindly say if any special soil is necessary, and should they be pinned before or after planting, or when?—M. B.

4847.—Sowing perennials.—It is too late in the season to sow seeds (perennials) salsolom. I am anxious to have a good show of flowers next spring and on the 15th of the season in a border that faces the house, and which has Lupinus, Delphiniums, Aquilegia, Campanulas, Gladiolus, &c.—PRESBYTERIAN.

4848.—Peaches and Tomatoes under glass.—Is it not possible to grow Peaches well on the back wall of a lean-to Tomato-house? I train the Tomato-plants on wires under the glass. The culture are 14 feet long, consequently there would be plenty of light until, at least, to the end of July.—AMATEUR, Devon.

4849.—Large Apple-trees.—Last spring I cut the middle branch out of four large Apple-trees to open them out. About six shoots have come from each out. I would like to know what to do with these and when to cut them back? They have all done well this year. Two are Lord Suffolks, the others are like Benhelm's—OUR SUBSCRIBER.

4850.—Cauliflower and Cabbages for show.—Will anyone kindly give me the names of the best Cauliflower and Cabbage (red and green) for exhibition, and when should they be planted on as to get them fit for showing by August? A few hints how to grow them would be very useful. Locality, West Riding, Yorkshire.—LEARNER.

4851.—Climbing Roses in a bleak place.—Will anyone kindly tell me the best kinds of climbing Roses, very dark red and white, and other colours, to grow in a very bleak place? The house stands upon the road, with fields all round about—nothing to shelter whatever. Also when to plant them? Soil, heavy clay bottom. Locality, West Derby.—E. J. H.

4852.—Violets in a conservatory.—Will someone be kind enough to tell me if I can grow these in a little unheated conservatory? I want them to bloom early. If I grow them outside should I need to protect during the cold weather? The soil is here good, and Bournemouth so mild perhaps they may grow well out-of-doors. Any hints will be thankfully received.—ELLEN.

4853.—Malmaloon Carnations.—I have a large quantity of the Malmaloon Carnations, this year's layers, potted and standing in cases in a sheltered part of my garden. The stems of a number of them are covered with a kind of "blister." The same is led with a reddish powder resembling rust. Will any of your readers tell me the cause and remedy?—S. H. S. K., Birmingham.

4854.—Maiden-hair Ferns.—I have four fine Maiden-hair Ferns. Two of them I keep in the house for a week at a time. They then are weak in the greenhouse, put on the floor. They are wasted, soaking them well, before bringing in, and afterwards they are taken up again to the greenhouse. Is this a right treatment? One of them is looking very pale and yellow.—FERRIS BANCA.

4855.—Rose Jean Ducher.—I have a Rose Jean Ducher against a wall, which grows luxuriantly and down freely, but the blooms do not open. They are clubbed, and fall off in a lump. I had two most abundant blooms spring and summer, but there was badly a good flower smothered them. Do you think the plant is worth preserving, or can you suggest any remedy?—E. B., Devonshire.

4856.—Renovating old Aparague beds.—When is the time to do it? Now? It is very old, and bears tolerably in the centre, but the sides have become worn away, and need the roots to be cut out. It is necessary to buy fresh roots for the sides, which are to be extended 1 foot 2 feet. Can you inform me of what material to rebuild sides, and if fresh roots are planted will they be fit for cutting in spring?—PIZZELL.

4857.—Tropaeolum speciosum.—I have a plot of this set out in a box 18 inches each way. It did not grow much during the summer, but has done so lately. Will someone kindly tell me the proper way to treat it during the winter? Is it factor east, and protected from the north and south winds; also is it well-work the best to train it on? Any advice as to its culture will be thankfully received.—STYVAX.

4858.—Greenhouse roof.—Will any of your readers give me any information regarding the durability of a new substitute of lead? It is unobtainable, and being a non-conductor of heat, would be much better both in summer and winter; but as it has a slight yellow tinge I am afraid it would injure the colour of the leaves, and by non-developing the green colouring, will make the plants tall and stately.—FERRIS BANCA.

4859.—Cut blooms for the house.—I am wishful to grow a lot of plants which will give me a succession of cut blooms for house decoration from early spring until frost sets in. Will anyone kindly give such a list, naming the months in which the plants bloom? I have already got a few sorts potted out and noted, but I have not seen a full list having special reference to cutting for house decoration.—E. COOPER.

4860.—Plum-tree not bearing.—I have here a large number of fruit-trees of about thirty years' growth, mostly bearing well, but the finest of all in shape and size is a Plum-tree, which, although a fine bloomer, for some years has not fruited. The tree is in an open space on side of hill, facing south-west; soil, heavy, wet clay. I have tried manuring heavily without result. Do not know whether I would a liberal cutting-back be of any use?—H. Z. C.

4861.—Rose Souvenir de la Malmaloon.—Will "J. L. O." or "P. U." kindly inform me if the above Rose is in free blooming and as lasting budded on the Brier as on its own roots? I am thinking of making a bed of Malmaloon Roses, and do not know whether to procure it budded or not. Dean Hole states in his "Book of Roses," on page 4, that it is essential it should be on its own roots. I could more easily procure them on the Brier. Would these do?—J. CROUCH.

4862.—Aralia Sieboldi.—I have in my greenhouse a fine Aralia Sieboldi, which has flowered again this year, as it did last season. I shall be much obliged to know whether the small, berry-like formations are the seeds, or whether, when the flower falls they will be produced there? I should also be glad to know whether I can propagate from seed, and, if so, how? The plant is a very strong and healthy one, and nearly 4 feet high. Its lower stems are rather too pendulous, to the detriment of its previous Palm-like effect.—LONGMAN.

4863.—A span-roofed greenhouse.—I have a greenhouse with span-roof rising from a 6 feet wall on the north side. It is 15 feet by 7 feet, seven, 5 feet high, and contains 6 feet. I intend having it sufficiently to keep cut fruit with one of the plants of Toop's stores. Will anyone contribute who has tested these kindly inform me on the following points:—1. Would a radiating hot air

apparatus or a hot water be the most effective as a heat producer? 2. Would combustion be equally good in either? 3. Which would wear best? 4. Would a common oil be so economical as a better kind? My questions relate to the differences between hot-air and hot-water stoves, not to the relative values of the different makers.—J. PEARCE.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4844.—Treatment of Cyprididms (J. W.).—You must not dry these plants during the winter. They have no real resting season, but require a somewhat lower temperature and less water.—M. B.

4895.—Odontoglossum Oro. Skinneri (T. Waktin).—Your plant of this, which has a spike of bloom from the top of the bulb, is flowering in an unusual manner. It should proceed from the base. Perhaps it has already bloomed from that place? I do not think you need fear any harm to come to your plant. I have had similar complaints from various parts of the country.—M. B.

4896.—Flowers beneath trees.—James Hudson says: "We have here some fine tall Chestnut-trees which stand beside the carriage-drive to the house. The ground beneath them is dry and bare at any time, but this season it has been quite an eyesore. What can I do to improve it? Well, now, I know of several good places, and I have advised the owners to plant it with St. John's Wort (H. celysinum), which produces good green leaves and large, handsome yellow flowers.—J. J.

4897.—Odontoglossum hastilabium.—Eric sends a fairly named variety of this plant for naming. It is blooming at a very strange time of the year. I have usually had this species flower through the spring months. It has been known for about fifty years, and it requires a slightly warmer temperature than many other species of this genus. I have found it succeed under about the same conditions as O. grande and O. Inesleyi; but it does not like to be so dry as these kinds in the dull season.—M. B.

4898.—Hemaphysads (Matthew Collins).—These plants are not all of the same set, although they belong to the same natural order, but the kinds from the West Coast bloom at different times to the Cape kinds. Many of the seedlings are extremely beautiful. The Cape kinds which you name should be potted in good loam, and be well drained, and when at rest they should be kept quite dry and in the greenhouse, but the kinds from the warmer parts of Africa should be kept in a cool stove, when dry and resting.—J. J.

4899.—Mandevilla suaveolens (the Ohili Jasmine) (C. Hubbard).—You have here one of the most lovely climbers that can be grown to the greenhouses, where space can be afforded it. As a pot plant it is most unsatisfactory, but when planted out in the border, well drained, and in a mixture of peat, loam, leaf-mould and sand, it will grow rapidly and bloom profusely, scenting the air with great fragility. When the blooms are past the shoots should be thinned, and those to remain should be cut back nearly to the old wood.—J. J.

4870.—Cyclamen flowers.—J. Hutchins sends me a nice bunch of these favourites. They are the first I have seen this autumn. He tells me these are from plants about fifteen months' old from seeds. The strain is superb. One thing I have noted about the growers of these flowers for market which I think is scarcely *au fait*, and that is the early flowers are all pulled for bunching up, and when the last whorl of blooms are open they are left on, and then the plants are run into the market and sold. This is a ruse that many of the buyers of the plants find out only when they late.—J. J.

4871.—Venus-fly-trap (Dionaea muscipula).—Inquirer sends a leaf of this plant, asking if it is not a Pitcher-plant, to which I must give him a flat denial; but it is associated with them as one of the carnivorous plants. The leaves are surrounded with long and stiff hairs, and the insides of the blades have numerous slender hairs, which, when irritated by the movements of a fly or other small insect, causes them to quickly close together like a trap; hence the vernacular name given above, as well as its scientific cognomen. The leaves remain closed whilst any movement of the insect is felt.—J. J.

4872.—Soldanellas (M. Wood).—These are all small growing alpine plants belonging to the order Primulaceae. They grow naturally near the snow line. The worst enemy they have to contend with as cultivated plants is the drought, but yet they do not like to be damp and wet. When grown strong and well they may be easily increased by dividing the roots. They should be well drained and the soil kept in a good porous condition. It should consist of good sandy loam, mixed with a little peat. The following kinds send most readily obtained, all of which are blue or violet: S. Clusi, S. alpina, S. minima, S. montana, S. pusilla, and S. Wharriell.—J. J.

4873.—Odontoglossum Lindenii (C. Curtis).—The flower you send does not represent a very showy or attractive kind. I at one time thought it to be an Oncidium, but at least I came upon some flowers which I obtained some years ago from Southampton, which put me right in defining your plant. It is a species which was found by H. Linden about fifty years ago, but it has not been in cultivation more than half that time. Its distinct yellow flowers are small, and the sepals and petals, although prettily undulated, are narrow. You may depend upon it that the Orchid is scarce, but there is little demand for it because it is not a pretty flower.—M. B.

4874.—Oncidium varicosum.—Orchid Lover sends a flower of this species, which is very brightly coloured, but it is by no means the variety Rogersi, and not even the large-flowered form called major. I do not know that it was sold with a view to deceive, but perhaps the person that sold it had never seen the true Rogersi, and in all probability my friend did not pay the true Rogersi price for it. I should imagine he is in a position to see a "Salicot Orchidaceous Plants," by Robert Welford. If he does not possess it, where he will find the true plant is in the second series, t. d. Yours is quite the Golden form of O. varicosum.—M. B.

4875.—Orchid-house (D. J.).—The house you have built for these plants should be devoted to the growth of Ostrileyas, and other Orchids which would grow well under strong light and sunshine, and you should have an iron framework put upon the roof to let your blind run upon, and to keep it about a foot from the glass, which would have the effect of maintaining a much lower temperature. Respecting the house you mention, 13 feet is a curious height for plants that do not exceed 2 feet, but I would advise you to fill the centre with Palms and Ferns, and to raise the side stages, and these might be used for the Odontoglossums and other cool Orchids.—M. B.

DUTCH BULBS.—Great unreserved Sales EVERY DAY. 4,000 lots sold weekly.

MESSRS. PROTHEROE & MORRIS will SELL BY AUCTION at their Central Sale Rooms, 67 and 68, Cheapside, London, E.C. EVERY DAY at 12 o'clock, large consignments of first-class Hyacinths, Tulips, Crocus, Narcissus, and other Bulbs from Holland, received direct; also Roman Hyacinths and other French Bulbs. Commissions are taken, lots packed and forwarded to all parts of the Kingdom. Sixpence remitted in stamps to the Auctioneers will ensure a supply of Catalogues for 12 consecutive Sales. N.B.—Sales of Plants in pots every Monday and Thursday; Orchids every Friday.

SPLENDID BULBS FROM HOLLAND. SELL BY AUCTION, WEDNESDAY, THURSDAY AND FREQUENTLY ON SATURDAY. IN LARGE AND SMALL LOTS TO SUIT ALL BUYERS.

MR. J. C. STEVENS will SELL BY AUCTION at his great rooms, 38, King-street, Covent-garden, first-class consignments of CHOICE HYACINTHS, TULIPS, CROCUS, NARCISSUS, and other Bulbs, arriving daily from well-known farms in Holland in the finest possible condition. On view mornings of sale, and Catalogues had free on application.

N.B.—NONE BUT GOOD AND RELIABLE BULBS will be offered.

BECKENHAM, KENT.—To be Sold privately, a DETACHED BIJOU RESIDENCE, suitable for a moderate-sized family, situated on high ground overlooking on one side an extensive park, bounded with fine old timber, and on the other commanding fine views in the direction of Forest-hill and Sydenham. The grounds, of about 1½ acres, are well laid out and planted with choice trees and shrubs. The tennis lawn is large, and the kitchen garden productive. The house is substantially built, the reception-rooms lofty and well proportioned, with convenient domestic offices on ground floor. There are on ground floor seven bedrooms, dressing-room, bathroom, &c. (with run), gardener's tool shed, &c. The property is held for a term of about 70 years, at a nominal ground rent of £4 10s. per annum.—Particulars from A. M., care Editor, 57, Southampton-street, W.C.

EXPIRATION OF LEASE.—E. TANNER begs to inform the public that he can offer his fine specimen and general nursery stock at half price. A grand lot of plants suitable for blinding out, suitably buildings. Also a large stock of fine Christmas-trees, &c. &c. E. TANNER, Broadwater Nursery, Groombridge, Sussex.

SITUATION WANTED as Head Working Gardener or good Single-handled, where help is given; good experience in herbaceous plants, House, Garden, &c.; age 37; married, no children; good character.—G. BUDD, Meadlands, West Hoathly, Sussex.

CRYSTAL PALACE ANNUAL CHRYSANTHEMUM SHOW, FRIDAY AND SATURDAY, NOVEMBER 3rd & 4th. For Entry Forms and Schedules apply to—Mr. W. G. HEAD, Superintendent Gardener, Dept. Street, Crystal Palace, S.E. ENTRANCE CLOSED FRIDAY, OCTOBER 27th.

PEARCE & HEATLEY WINTER GARDENS, CONSERVATORIES, &c., &c. IN ALL STYLES. Plans and Estimates on application. Surveys made.

"HOLLOWAY" BOILERS. GREENHOUSES IN GREAT VARIETY "EXCELSIOR" PROPAGATOR from 24s. GARDEN LIGHTS.—6ft. by 4ft. from 4s. 6d.

CUCUMBER FRAMES.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR SMALL HOUSES.

If Chrysanthemums are wanted purely for the greenhouse, not for showing, they must be grown naturally—that is to say, with little stopping of the shoots or removal of the buds. To let a plant grow in its own way under glass signifies that it produces a profusion of very small blooms and looks weedy. In the open one need stop very little, or not at all, as there, even if small, the flowers make a show of colour. Beautiful plants may be got very easily if careful attention is given to all stages of growth, to get them clothed with foliage to the base. Each stem should bear a flower or flowers, and when in full beauty such plants give far more pleasure to friends than the severely trained specimens—the blooms, as it were, dotted over the surface. The outtings need not be taken before the month of February or early in March, and they may be either placed in 5-inch pots, filled with good soil all round the sides, or singly in 6-inch pots, the latter plan being preferable. Loam and leaf-mould, mixed with a fair proportion of sharp silver sand, forms the best compost, and put under such outting a little sand; this makes the chance of "damping" off less remote. Put a few crocks in the bottom of the larger pots, and one or two in the smaller ones, to prevent damping off. Use new pots if possible; but whether new or old they must be quite clean, and if new soaked a few hours in water before being used. The Chrysanthemum is naturally hardy, and the fine old bushes one sees in cottage gardens are evidences of this—glorious masses that have braved many winters unharmed. Avoid oddling the outtings; although they may be struck in an ordinary cold frame there is danger from frost. It is better to have a propagating frame in an ordinary greenhouse, with a temperature of about 45 degs. When growth is commencing give air and water cautiously, otherwise they will damp off. When the outtings have filled each little pot with roots shift them singly into 4-inch size, and stop them when about 5 inches in height. The next and only other stopping should be when they are in 6-inch pots, the time to shift them into these being April. Some kinds will require further stopping, but not the majority. Grow them freely throughout. Few plants suffer more from check than the Chrysanthemum, the growth getting stunted. Always, therefore, attend closely to such simple operations as potting and watering. The plants are better if kept in the greenhouse, and plenty of air maintained about them. Where there is no greenhouse the frame must be used. The final potting must be given, and early in June or late May is the best time. The 6-inch pots must be full of roots, and the final size will be 9-inch or 10-inch. Turfy loam is the chief ingredient in the soil—say, four parts, to which add well-decayed manure two parts, leaf-mould one part, and a sprinkling of crushed bone and soot, with sufficient sharp silver sand to keep it fairly open.

Mix the whole thoroughly well together, and if too heavy add a few particles of charcoal, which will help to keep the compost open.

POT FIRMLY.—This is most necessary, and use a potting-stick, as it is not often one can make it firm enough with the hands. In the earlier pottings it will not be necessary to use a stick, as the soil may be made sufficiently firm in the usual way. On the clean well-arranged crocks, place a little of the rougher parts of the compost, which prevents the finer particles of soil from getting down and stopping up the drainage. During the summer keep them in the open in a moderately-sheltered spot, standing the plants upon a layer of coal-ashes to prevent worms from getting in the bottom and disturbing the drainage. During the summer, and until the buds are expanding, manure-water must be given, giving first cool water, but in July this may be alternated by liquid-manure; give weakly at first, but as the plants advance towards the flowering stage of increased strength. No liquid-manure must be given until the pots are well filled with roots. As regards disbudding, as the varieties grown in this way consist chiefly of the Japanese, remove the crown bud to promote the production of shoots. One cannot give any hard-and-fast rule, as in some cases, the singles for instance, the plants need not be disbudded. It must not be thought that there is any limit to the list of varieties for culture in this way. All, or at least the majority, of those seen at exhibitions may be grown thus. I have seen plants of Edwin Molyneux bearing splendid blooms, and a plant of it in full beauty is a picture. Lady Salborne is delightful when seen bearing dozens of its pure-white flowers, La Nymph (rose-purple), and Tendresse (light-mauve-lilac) can be made literally mounds of bloom by this process. Very beautiful amongst single kinds is Miss Rose, the flower large, and the plant is remarkably fine. It is impossible to see the leafage for blossom. Mary Anderson, a good white, is almost as vigorous, but the flowers are larger. The beginner should leave the Incurved kinds alone, and commence with the Japanese and Singles. This natural way of growing the Chrysanthemum must not be confounded with the outting-down process. The outting down is simply to reduce the height of the plant. Cut down the late-flowering varieties first, then those that bloom in mid-November, and the early-flowering kinds, such as Klaisa, in the middle of June. If very dwarf plants are desired, cut them down to about 5 inches of the soil, and the others from 8 inches to 1 foot. When out down, place them, if possible, in a cold frame, water with care, and syringe daily to promote the growth of sturdy shoots, which should be thinned out to about three to each stem, selecting the strongest, two or more being retained if the varieties bear small flowers. This having been done, repot them, and 9-inch pots will be quite large enough for the final shift. When fairly established in their new pots place them in the open, allowing plenty of space. It will be well to put a stake to each shoot, and choose the first buds that appear for the production of flowers. They should be rubbed if they appear before mid-August. With plants, with this treatment, will be quite dwarf,

clothed with rich green foliage to the edge of the pots, and the flowers of good size. The outting-down system is closely followed by many growers, especially when they wish to make neat groups. It is a reaction from the former plea by allowing the plants to grow 8 feet or even 9 feet high—tall, lank specimens, with one or two blooms perched on the top of the quaint stems. Some varieties, such as John Sewerd and Avalanche, are naturally dwarf. V. C.

4813.—Growing for market.—It is very difficult to advise anyone what to grow for profit, without a knowledge of the locality, for nearly everything hinges on whether you are close to a market, as some goods will hardly pay for carriage, but if you are within easy distance of a market, you may grow a good many things in such a house as described. French Beans would do well, especially after Christmas, when the sun's rays help vegetation very much under glass. Early Potatoes, of the kidney type, or Sharpe's Victor, if planted at once in the soil in which the Cucumber or Tomatoes have been grown, enriched with some good loam and leaf-mould, and a row of Scarlet Radishes could be grown between each row of Potatoes, and pulled for market before the Potatoes needed all the space. But if there is a ready sale close at hand I should say salading of various kinds would pay as well as anything. Mustard and Cress give a very quick return. Lettuce, if good strong plants of the Cabbage kinds are available, ought to sell freely—at least, the French make a lot of money out of them in spring. Young Carrots of the Short French Horn kinds might be tried with success, and if you have strong crowns of Rhubarb, lift them and replant in the house, for all these sort of things sell if got in early. Green Mint is very easily grown, and comes on with a very moderate heat, but you must not expect very high prices. There is too much competition for that nowadays.—J. G., Gosport.

Begonia tubers.—Do not despise little tubers of Begonias raised from seed sown this year. They are now going to rest, and should be kept on the dry side all the winter, where frost cannot reach them. They may be left in the seed-box untouched in a spare room. In the spring, with returning warmth and a little moisture, it is most interesting to watch the little seed-like tubers starting into life. Give them the warmth of the sun's rays or other genial heat, with not too much moisture, and they will soon be ready for potting off into small pots filled with a light rich compost. Free ventilation produces a sturdy habit of growth, and they seem to thrive all the better for a syringe once a day (before noon) until the buds appear.—G. H. W., West Brighton.

Petroleum and water.—I think that some of our readers would be glad to know of an easy method of mixing petroleum with water. Take two parts of milk and one part petroleum, mix well. The paraffin will then mix freely with water for use as an insecticide.—ARTHUR ELSON.

4807.—Using manure.—By all means lay up the manure, let it decay, and dig it in in March or April. Nothing so soon renders soil soft and fills it with worms and other insects as covering it with manure during the winter. (Rubbish, well-decayed material is much better for most herbaceous plants than fresh.—B. C. R.)

GARDEN WORK.

Conservatory.

We are fast approaching the short dreary days of winter when blossoms under even the most careful treatment will damp. The atmospheric conditions must be fresh and buoyant, and to ensure this steady fire will be necessary, so that air may be given more or less every day when not raining or freezing. In summer plants in bloom will use up a good deal of moisture, and if more than is needed is given, no great harm will be done; but in winter if too much water be given to Chrysanthemums or other plants in bloom it interferes with the opening of the flowers in more ways than one. Some of the large blossoms of Chrysanthemums are difficult to keep, chiefly owing to the high feeding which has resulted in the abnormal size. Where many Chrysanthemums are grown, some at least should be grown more naturally than the large blooms are for the sake of their keeping properties and for cutting purposes. The large blooms it is true make a grand show when cut for a short time, but they will not keep. Give liquid-manure to Chrysanthemums in small pots. Camellias also and Azaleas will be benefited by an occasional watering with weak clear liquid-manure. It is now the fashion where there are several plants in a house to group the plants together in families, thus Cyclamens and Chinese Primulas may be grouped together. Hard-wooded plants again do better by themselves, a few temperature-suiting ones of these better than when much heat is used, especially when the atmosphere is moist and stuffy. Australian plants will bear more heat than would be good for those Cape Heaths and East plants, though it does not follow that the Australian plants are the better for so much heat. A little artificial heat from this onwards through the winter will be desirable to keep up the necessary buoyancy of the atmosphere; but harm is more likely to be done by giving too much heat than too little. After fires are lighted regularly the borders where plants are growing in them must not be permitted to get too dry. Camellias will take a good deal of water at the root now. It will be advisable, if the plants are heavily laden with buds, to give them some, so that each shoot only carries two or three blossoms. Lonicera gratissima will now be showing flower-buds, and should have weak liquid-manure occasionally. The Hebeanthemum family are showy winter-blooming plants. For covering walls and pillars they are most useful.

Stove.

Give Eucharis Lilies which seem disinclined to throw up flower-spikes weak liquid-manure—Cley's Fertiliser or Ichtheolin (which will do). A course of treatment of this kind if the plants are strong will soon bring up the spikes. Late-stroke Primulas may also have an occasional dose of Cley's or guano to give substance to the scabrid bracts. These are plants which should be a strong feature in every stove now, and a few plants of the white variety form an agreeable change to so much azalea where a large number are grown. Rivina humilis, a neat-headed, berry-bearing plant, is useful for winter decoration. I have used it sometimes for table-decoration for a change. Another pretty little plant at this season is the Centrodia rosea. When small standard plants were fashionable for the dinner table, these and other things were trained up to straight stems with a bunch of leaves and blossoms on the top; but it had an unnatural look, and the mop-headed plants did not please. Keep a very keen eye upon the plants liable to insect attacks. Watch for mealy-bug, and give it no quarter; it is the only way to keep it under. Night temperature about 65 degs.

Ferns Under Glass.

Should slugs or snails be troublesome, lay some greased cabbage-leaves about, and examine both the Cabbage-leaves and the Ferns every night with a light. They may be easily captured when feedling at night. The small slugs are often troublesome on Maiden-hair Ferns, calling the young froods as they emerge from the crown of the plants. Ferns must not be permitted to get dirt dry at any season. Do not crowd the plants; it spoils the shape, and the fronds turn brown when much crowded. Specimens of Adiantum Falcifolium should be elevated a little to bring them into the light. No shading is required now. When a larger stock is required it is better to divide young plants than old ones. When large old plants are out up many of the pieces from the interior of the specimen may die.

Orchard-house Trees.

Any trees which require repotting or top-dressing should have been attended to before the leaves were down, though the leaves on trees in the cool-house are hanging longer than usual this season. In most gardens the orchard-house is filled with Chrysanthemums in autumn, and the trees turned outside, the pots being protected when frost comes with leaf litter. A little of the litter should be laid over the top, but not piled up the stems, as it may become a hiding-place for mice, and if the stems are covered the mice may nibble the bark under the litter. I have seen the trees injured in this way.

Cold Frames.

Give all the air possible to Violets, Camelliflowers, and other hardy subjects, but keep out cold rains. Hardy plants, such as chalice aloe, wintered in cold pits or frames should have the pots plunged up to the rims. Carnations wintered in frames will be better if the pots are protected with Cocoa-nut-shire or dry ash.

Hot-beds for Forcing.

May be made up according to requirements. Leaves and manure in about equal parts make very safe beds. There is no fear of over-heating. The roots may be planted at once. A good size for beds at this season will be 4 feet in back and 3 1/2 feet in front. Must be built up firmly, so that the heat may be regular and steady.

Window Gardening.

The main object now is to keep plants healthy, and to move on steadily. Water must be given to evergreens when required; but during the short, dark days the con-

* In cold or northern districts the operations referred to under "Cold Work" may be done from ten days to a fortnight later than is here indicated with equally good results.

sumption of water will be much less. Ferns in a growing state must be kept in a reasonably moist condition, but not saturated. Ferns never do so well in a room in which large fires are burning daily, and perhaps gas at night, as when only an occasional fire is lighted. Some day in towns everybody will have the electric light, and then plants will flourish with less care.

Outdoor Garden.

The beds are now pretty well cleared at the summer hedgers, and in the country the next few days many will be filled with bulbs and other spring flowers. Variety is always alarming, and where there is more than one set of beds or borders different styles of planting should be adopted. Beds filled with some of the handsome little gold and silver shrubs are dreary in winter, but they would be rather expensive, though if taken care of they will last several years. Some of the best things for shrub bedding are Cupressus Lawsoniana, Crocus viridis, C. L. Jutea, C. L. alba, C. L. Fraseri, Redinopis plumosa, E. p. aurea, R. aquifolia Valtia, New Golden Irish, Thujus, Crocus viridis, T. veranensis, T. occidentalis, Lilius Juniper, variegated Lilius, Eumyrtus in variety, and Aucuba in variety. The beds need not be filled with shrubs. They may either be grouped in the centre, or be so arranged as to form recesses of either regular or irregular outline for sheltering masses of various kinds of bulbs or other spring flowers. Then as regards edging, more use might be made of the hardy Hesperis where the soil is suitable—in light, sandy districts. There is much variety in the hardy Hesperis, and good plants can be bought cheap. Daisies, again, white and red, will flower all the winter if the weather continues open. I saw a bed of white Daisies the other day, which by their freshness reminded me of spring. Tufted Pansies are among the brightest things in beds or borders in spring. Beds or groups of young Lavender or Rosemary are very effective now. Sunb stock is easily propagated from cuttings or raised from seeds. Vinca clethra and Vinca major are very charming now. Beds of Pansies should be got in now. It is time also Tulips were all planted. A friend of mine always pots his bedding Tulips, and plunges the pots in the beds, his object being to clear the beds early to make ready for bedding out.

Frut Garden.

The best Grapes for a cold-house are, I think, certainly Black Hamburg and Alicante. Both of these under ordinary conditions and fair treatment may be relied upon to colour well and ripen in good time in autumn. There is no doubt, of course, that the Alicante would be improved by a little fire, not only in spring but all other seasons if there came a wet cold week any time. Gros Colmar is a very fine Grape, but must not be over-cropped or it will not colour well. Foster's Seedling, though a good early forcing Grape, is of no use for late use, it is too small in berry. Anyone may tolerate a small Grape early in the season if the flavour is right, but it is quite another thing after August when the big Grapes come in. I never recommend old Vines to be got rid of when they are doing good work, but if a crop has to be sacrificed and a new border made always put in young Vines; they will stand more wear and tear and produce finer fruit than very old ones. The best time to plant a vine is, I consider, in spring, say about March or April, when the Vines are breaking naturally, and they are very often planted too near each other. Three feet is a very smaller distance which should be allowed for certain kinds, such as Golden Queen, Muscat, and Gros Colmar, I think 4 feet would not be too much. Golden Queen does fairly well in a cool house, and is a far away better Grape, except for forcing, than Foster's Seedling. Push forward the planting of hardy fruits. Remember that Apples on the broad-leaved Paradise are best for the small garden, only they being suitable rooting must have rich top-dressing in summer. Schilville, Laur's Prince Albert, Cox's Orange Pippin, Henshall Orange, and Starling Castle cannot well be beaten.

Vogtable Garden.

Numbers for bearing in February and onwards may be planted and taken on readily till the shortest day in past. Plants in bearing must not be heavily cropped, as if too much exhausted they will probably go off about February. The chief cause of injury is leaving the fruits hanging too long. Out as soon as fit for use even if some have to be given away. Very little ventilation will be required now, only just enough to cause a gentle circulation. Keep up steady fire. Hot pipes mean lowest attacks generally, especially in small houses. Occasional top-dressing with fresh turk manure is much valued. Do all the mending with the finger and thumb till next March. This is only a question of stopping the shoots in time, pinning out the terminal buds will then suffice. Hot-beds may be made up now for Asparagus, Spinach, Rhubarb, Lettuce, and Carrots. French Beans will do better in pots in warm houses. They will come on very well in the Pine-stove. Second crops of Tomatoes will be heavy on healthy plants. Under good management it is no uncommon thing for Tomatoes to continue growing and bearing for a year. As they have been started in the beginning of the year by training in a succession of young shoots, they will continue to bear till the following Christmas, or even later if the right kinds are planted. In properly heated houses Tomatoes ought to run twelve months. It is only a question of keeping the plants healthy and giving nourishment. All the Celery, even the latest crops should be earthed up now, and there should be a stock of dry Fern or litter at hand for protection should severe frost set in. Up to the present Cauliflowers have been fine and received no protection except breaking a leaf or two over the heart, but the plants should be lifted and laid in some dry border where they can be easily covered when frost comes. E. HODDY.

Work in the Town Garden.

At last the frost has come and out of all plants of a tender nature outside. After a sharp night there is very little left now except the Michaelmas Daisies, Chrysanthemums of the harder kinds, Veroloca, Laurustinus, and such things as Violeta, and the like. These in flower are simply intended to grow in large towns; I have tried it over and over again, in all sorts of ways, and both indoors and out, but all to no purpose. Although Chrysanthemums in the open may remain in bloom more or less for some time longer, the flowers will have a weak-

dried appearance, but those grown under the protection of glass are vastly cleaner and brighter. The season of indoor gardening may indeed be said to commence now, for within the precincts of a town there will be very little of interest in the outdoor department from now until April is well in season at the earliest. Clear away the last of the bedding-plants at once, and refill the beds either with bulbs of sorts or with neat dwarf evergreens, such as Eucyrtus (green and variegated), Aucuba, Box, Arbutus, Rhododendron, and Skimmia. Consider of setting in small growing varieties, look well for a time, but they cannot endure a smoky atmosphere they soon assume a shabby and miserable appearance, and sooner or later give up the ghost altogether. Unless Hyacinth and other bulbs are got in at once they will not do much good; it is quite late enough now. If after planting the beds are mulched with a couple of inches of fresh Cocoa-nut-fibre it will produce a very neat appearance, and tend to protect the tender tops when they rise. The best way to cut the stems of old Zonis (if Clematis) is to lift them carefully, shorten back the stronger roots, and either plant them singly in small pots (3 inches to 3 1/2 inches), or thickly in boxes, in either case with free drainage and some rather sandy soil made quite firm around the roots. Water them in well once, then let the lollaige dry, and remove to a heated greenhouse or sunny window, giving water very sparingly especially during severe weather, until the spring. Such old stumps always furnish plenty of nice cuttings in the spring, as if these are not wanted they will flower early and very freely, and make very stout, bushy plants. In the greenhouse every thing must be kept scrupulously clean and neat now; dirt, dead leaves, and insects are three deadly enemies to healthy growth under glass. Water should be given chiefly in the forenoon now, and then only to such plants as really require it, especially where the temperature is low. It is not as much frost-hent yet, except to stove or very tender plants, but frost must be well provided, and enough to be not wanted they will flower early and very freely, and keep the air in motion and prevent damping or decay. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from November 11th to November 18th.

Potted up Mint, Tarragon, and Chervil, to have a stock ready to hand when required. Moved all tender plants from cold pits to houses where the frost can be kept out. The stocks of bedding plants in cool quarters, but there are the means of keeping out frost and expelling damp when required. A very small amount of artificial heat will suffice for this if the plants are hardened by free ventilation. Shifted late sown Chrysanthemums and Primulas to flowering pots. Nothing larger than 6 inch pots has been used for these. A nice little specimen can be grown in a 6-inch pot, as a little manure can be used at the finish if necessary. Chrysanthemums coming into bloom are receiving a solution of Ichtheolin guano every second watering, and the water roots come in to the surface as if they were anxious for the Ictis stimulant. Plants in small pots require something, and they pay for it. Cleaning Vines in early viney, afterwards whitewashing walls. House has been recently pointed inside and out. Outside borders have been covered with dry leaves and thatched with straw. The leaves will probably ferment a little and a little warmth may perhaps penetrate the surface, but not enough to unduly excite the Vines. Vine roots, if healthy, in a well made border will do their own better without much excitement, and the covering of leaves will keep up the temperature by preventing the escape of the summer warmth. Looked over the stock of Caladluma packed away on their side, see if there were any symptoms of disease. Have lost one of the delicate varieties through dry rot. Stragoc roots keep well in a dry state, but some of the delicate sorts are better not dried too much. If dried off thoroughly I find them do better in a rather cooler place than the stove. Gloxinias also keep more vigorously when not packed to the wall in winter. Made up a hot-bed with leaves and manure for forcing Asparagus, and having plenty of leaves a bed has been made for gently forcing Lettuces. The frame has also filled nearly to the top with leaves and soil, so that the plants will not be more than 4 inches or 5 inches from the glass. A little ventilation will be given and coverings will be used at night to prevent undue radiation of heat. Rearranged conservatory as so to make the most of the Chrysanthemums which are now in good trim, but every grower who has a little variety knows how difficult one of the varieties are to keep in condition, and how difficult it is to be careful in watering. Some people think they cannot give these plants too much water when in flower, but this is a mistake. The flowers on plants where the soil is in a constant state of saturation can suffer from damp. Pruned Gooseberries and bush fruit generally, spool attention is given to thinning, but to leading shoots are left rather long as the best fruits are borne there. On the contrary, lead Currants are spurred in close and only a few inches of young wood left at the top.

Growing Carnations.—I have read with great interest in GARDENING many articles on the growing and wintering of Carnations and Ploetees. I, myself, am a large grower of many years' experience, and I find, in planting out in the open, say in September and October many of the choicest varieties perish during a very severe winter. I now adopt the following plan with success: In October I take up carefully the layers of my Carnations and run them out in cold frames in sandy soil, adding a inch row mixed leaf-mould and sand; tread down firmly the plants. I put them 4 inches between each row, then give them a good watering, put on the lights, and tilt them up with tiles top and bottom of frame, so that a free current of air can circulate through during the autumn and winter months. Carnations do not grow so readily; it is the wet that rots them off. I have grown them in pots, and covered them in shades in cold frames, but I have not found it as satisfactory as planting out in the soil in row in March. Take off the lights when the weather is fine to harden them off, and plant out in borders or beds second week in April. I never water the plants from the time of planting in the frame till April. Aspect of frame south.—GEOFFREY.

THE KITCHEN GARDEN.

FORCED TURNIPS.

It does not appear that the Turnip is forced to any great extent in English gardens. In France, on the contrary, the forwarding of this vegetable forms an important item in garden operations. In most large private establishments a supply of early Turnips is considered indispensable; and such is the demand for this vegetable in Paris that very many market growers in the vicinity of that city make a speciality of its culture, some of them devoting a great number of frames thereto. For the first crop, which should be ready for use by the beginning of April, the seed is sown about the middle of January, suc-

Long Forcing Turnip.

cessive sowings being made to maintain a supply until the first open-air crop is ready to pull. Some years ago the Parisian market growers relied entirely upon manure-heat for forwarding such things as Carrots, Turnips, &c.; now, however, many of them have adopted hot water for the purpose, affirming that by its means they can obtain better results in less time. These early Turnips are really very good, and form early in the year an agreeable change in the vegetable supply. The culture is simple, a slight heat, sufficient to promote growth without inducing a too rank leaf development, accompanied by free ventilation on all favourable occasions, being the principal points to observe. J.

4838.—Carrots for show.—The best varieties are Scarlet Short Horn and the best variety of the Scarlet Intermediato. At most shows there are separate classes for these varieties. Get the ground trenched up now, and if the subsoil is bad keep it below. Work in all the light rich compost available—wood-ashes or burnt earth or charred rubbish. No fresh manure should be applied, but if the land is trenched a layer of manure may be placed in the bottom of the trench. Leave the surface rough, so that the frost can penetrate. Early in February give a top-dressing of lime and fork it in, and about the end of March or early in April—according to the weather—give a sprinkling of super phosphate, about 5 lb. or 6 lb. to the square rod, rake level, make firm. Draw the drills 15 inches or 18 inches apart. Sow the seeds thinly; cover by “shuffling” the feet along the rows, and rake down. Thin to 9 inches apart when large enough.—E. H.

4843.—Onions for show.—Get a good strain of Magnum Bonum. Sow a part of the seeds under glass in a gentle hot-bed in February; harden off when about 4 inches high, and then plant out in rows 1 foot apart, and 6 inches apart in the rows. Trench up the land and thoroughly manure it in winter. In February give a dressing of soot and some artificial manure, and fork it over again, and when the surface is dry in March sow the remainder of the seeds in drills, and when the young plants raised in the hot-bed are sufficiently hardened plant them out at the distances named above. Good culture, if given, will do the rest.—E. H.

4842.—Early Peas under glass.—There is no doubt good Peas could be grown in the Tomato-house, and if planted in December one

of the dwarf early Peas might be cleared off in time for the Tomatoes to be planted, though I doubt if Peas may be grown under glass so well as Lettuces or Parsley, or even Mint. American Wonder is still, I think, one of the best for planting under glass in pits or houses, or to grow in pots. Chelsea Gem is also a good kind.—E. H.

—Early Peas can be grown in a Tomato-house, but they cannot be expected to do well under the Tomato plants. They will succeed in any house if placed in a light position near the glass roof; and they ought also to have as much fresh air as possible. If sown on the first of December, and not forced too much, they would come into bearing early in April. The dwarf growing early Peas are best for forcing; they do not grow more than a foot high in flower-pots and bear very freely indeed. Chelsea Gem, American Wonder, and Carter's Daisy Pea—the last named is a distinct and handsome variety, producing much larger pods than the other two.—J. D. E.

4856.—Renovating old Asparagus-beds.—Increase the width of the beds by trenching and a suitable width on each side now, but do not plant till next April. As you want to get the bed into a bearing condition as soon as possible, purchase two-year-old plants, but do not cut anything first year, nor yet from the weekly plants the second year. It is this herd cutting which causes Asparagus-beds to wear out. The roots on the sides of the beds should not be allowed to get exposed. If you have space try the culture of Asparagus on common-sense principles by planting in rows 3 feet apart on the natural level, or even a little bit below it if the soil is deep and affords plenty of rooting-space. It is the crowding of Asparagus-plants together in narrow beds which kills them. An Asparagus-plant, if permitted, would easily fill a space a yard in diameter or more, and this free development would add immensely to the size of the crowns.—E. H.

EARLY PEAS.

VARIOUS ways are adopted in order to get Peas early; some sow in pans or boxes under glass, and afterwards plant them out, and others sow in the ground in the autumn when they are to remain. The first plan entails the most labour, but it has the advantage of being the surest, as the Peas are more out of the way of birds, rats, and end mites, as well as slugs, than when in the ground. The latter are such pests in some soils that it is almost impossible to prevent them from devouring all early green crops. In light, warm lauds, free from slugs, Peas may be sown any time now with every chance of success, but to make sure of them germinating it is not only necessary to secure good, sound, fresh harvested seed, but to have the ground in good order before putting them in, for if wet they are almost sure to rot, and to prevent this it is advisable to cast over them a little dry ashes or earth; either of these absorb the excess of moisture, and give the Peas a chance to make a fair start. To ward off mice I have known them covered with chopped Furze, but the best way is to trap the vermin, which may easily be done by means of a brick or tile with a piece of Rallis Grass and bait tied in it, in endeavouring to get which the mice bite through the Grass and let the tile or brick down. The way to set the tile or brick is to place a stick in the ground for the purpose of tying the Grass to, and having secured the lower end on a level with the earth, the brick or tile should be stood on it so as to bring the bait about 1 inch up the face, when the other end may be made fast at the top of the stick, leaving the brick or tile sloping at an angle of about 45 degs. Good traps may also be made by the use of pieces of lath, cut to form the figure of 4, and very small steel spring traps, made like those used for rabbits or rats, are sold at ironmongers, which are femons for catching mice and small birds. The best place to grow early Peas is on a warm border sloping to the south, where they should be sown in drills drawn about 3 inches deep, and from 3 feet to 4 feet apart, according to the kind grown, but whether tall or short, it is always advisable to give plenty of room between, so as to let in sun and air, on the full influens of which success in a pea-treasure depends. After trying many sorts I find none equal as a first early to Kenil-

Invicta, which not only is the earliest by some days or a week over all the newer kinds, but it is a prodigious cropper, and the Peas are of a fine deep colour and most excellent in flavour when cooked. To succeed this I should recommend William I., which should be sown at the same time; and to follow on after William I., Day's Early Sunrise, Taber's Perfection (or Dickson's First and Best) is also good, and the kind here figured, Earliest of All, is said to be an early variety of great excellence. In cases where sparrows are troublesome and eat the young tops of Peas, the safest protection are the Pea-guards, made of galvanised wire, which, although apparently dear at first, are cheap in the end, as they last a lifetime; but where these are not used a few strands of cotton run up and down each of the rows will generally keep these bold depredators from doing much harm. S.

NOTES ON DAHLIAS.

THE Cactus Dahlias show a marked advance each year, and it is worthy of note that this season the new kinds are of the true character. The type of flower that should be encouraged on the “decorative” kinds are not “Cactus,” although they sometimes pass as such. When Juarez was introduced by Mr. Cannell, a distinct era, so to speak, commenced. This still is one of the best of the “Cactus” class, but hides its scarlet flowers too much amongst the leaves. At exhibitions separate classes are now formed for this class alone, and when set up in fine bunches, their distinct shape and rich and varied colours are shown off to perfection. Hybridists will, I hope, add more still to this beautiful class, and the plants are more free-blooming, whilst the flowers are seen to greater advantage than in Juarez. One of the most distinct varieties is Countess of Gosford, which has small flowers of pretty shape, the florets slightly twisted and pointed. They are small compared to the others, and of a distinct yellow, shaded on the outer florets with rose. Bertha Mawbey is a handsome variety, the flowers large, and the florets charmingly twisted, gradually tapering to a point, quite distinctive of the old Juarez. The colour is a distinct gain; but the riser must guard against getting into the flowers deep purplish-magenta shades, which have spoilt many beautiful garden flowers. Bertha Mawbey has flowers of a deep-crimson colour, over which is spread a magenta shade, like a satiny lustre to the blooms. Countess of Radnor has blooms of a “Cactus” shape, and of delightful colour. This is a very beautiful variety, the colour yellow, touched with brilliant

Pea "Earliest of All."

carmine, shot with a pellucid tint. Mrs. Basham has flowers of a very pretty rose colour, and of good shape. Delicate is a lovely red-rose, and allied tints melting one into the other, and a beautiful kind is Lady Florence, clear pale yellow, one of the most beautiful of all the Peas. OF ILLINOIS AT URBANA-CHAMPAIGN

INDOOR PLANTS.

EUCCHARIS LILIES IN A COOL GREENHOUSE.

LAST winter a friend who had just returned from Ceylon gave me a quantity of bulbs which he had brought with him. These I found consisted of *Zephyranthes*, *Pancratium*, and *Eucharis*; in all they filled 70 pots when planted. The *Zephyranthes* I fully expected to bloom, and I was not disappointed, for I knew what they could and would do beforehand; but, although the *Eucharis* grow rapidly and looked wonderfully healthy, I was under the impression that they required considerable heat and constant attention to make them bloom. However, these plants are now rapidly developing both buds and flowers; one is already out, with as fine a cluster of bloom as anyone could wish to see, like a gigantic pure-white *Narcissus*, with petiolated or caudate petals and delicious scent. Mentioning the fact to a friend, he informed me that I should fail next year. "The flowers," he said, "were already formed in the bulbs when you potted them, but in India we often attempted to grow *Eucharis* out-of-doors in the Nellcherries, and they never flowered after the first year." I do not feel convinced, for it might be suggested that *Hedyolum Gardnerianum*, though it should flower a first year under cool treatment, would subsequently fall, and yet it produces year after year grand spikes a foot or more in height, and from 8 inches to 9 inches through at the base. The winter temperature of my cool-house sometimes falls as low as 48 degs. Fahr. I have no stove, and my small growing house is awkwardly situated as regards north-east winds, so that it is often impossible to look upon it even as a temperate house when sharp frosts and east winds come together. The *Pancratium* I can hardly expect to bloom, and I was not a little pleased at my success with the *Eucharis*.

A. G. BUTLER.

4790.—*Lobelia erinus*.—The proper way to winter *Lobelia* of any kind is to preserve a limited quantity for stock—say one dozen pots or so of which a great number can be got. After the best time in spring pot up in 5-inch pots, with a good sandy loam and plenty of drainage. After this stand them outside on a good bottom of coal-ashes. If labour is no object plunge the pots to the rim, thereby saving labour in watering. If they are kept dry they cannot possibly grow. Never let plants exhaust themselves by blooming. What is wanted are plenty of young growths. House before any frost beats them. Many people let them stand through the winter as they are. My opinion about *Lobelia* is that it wants to keep growing. I have a number of boxes prepared and filled with a nice, rather sandy compost; then my plants are divided and put into them, giving them plenty of room so as to guard against damping. If it does appear cover well with dry river-sand among the plants. I have at the present about fifty boxes on shelves in a *Chrysanthemum*-house, and the ventilators have not been down yet, except for wind. Air is a thing that must not be neglected in keeping *Lobelia* through winter, or the result will be very disastrous.—F. G. PETERINGER, Harrogate.

4853.—*Malmalson Carnations*.—The plants of the *Malmalson* are attacked by a very destructive disease, *Uromyces ostryopbillimus*. The reddish powder is the spores of the fungus, and one of these minute spores falling upon a healthy leaf will soon develop into a blister, which will in its turn burst and scatter thousands of spores. The only way to get rid of it is to cut off and burn the affected leaves. It may be necessary to almost entirely denude the plants of leaves, but there is no other effectual remedy.—J. D. E.

4839.—*White Pearl Tuberoses*.—*Tuberosa* may be grown in a cool-house, but the flowers will not come so fine, and the plants will, of course, be much longer before they flower—for instance, I had bulbs potted last March, and grown cool, which did not flower till the end of the summer. The *Pearls* are not in yet—at least, my stock has not arrived yet (Oct. 30th); but if potted and kept in cool-house they will not flower before next spring, possibly later.

ARUM LILIES (RICHARDIAS).

THESE are everywhere in demand about Christmas and Easter, and great numbers of them are brought into the market during these two periods. By some they are grown in pots throughout the whole year, while others, to economise labour, plant them in the open ground. Apart from the labour question (generally an important one), they form much stronger plants, and are therefore more likely to flower when planted out than when confined to pots throughout the season. Being semi-aquatic, a

Richardia tetiopiaea and R. "Little Gem."

low-lying, but sunny spot, where plenty of water is at hand throughout the summer, suits them best. Towards the end of May they may be turned out of the pots, the soil shaken from them as far as possible without injuring their roots, and divided into three or four sizes preparatory to planting out. After all are planted, a good watering is given to settle the soil about their roots, and should the weather be favourable they soon commence to grow away freely. The only attention required during the summer is to keep them clear of weeds, and give a thorough watering whenever required. Thus treated, most of them form good, sturdy plants by the end of the summer or beginning of autumn, when they are carefully lifted, potted in some good open, loamy soil, and kept close in a frame till root-action recommences. At all times water must be liberally supplied, and when the pots are filled with roots a little liquid-manure may be advantageously given them. The seedling known as "Little Gem" grows from 9 inches to a foot in height, and it is a useful little plant. The illustration shows the ordinary form of *Richardia* and the seedling variety alongside of it.

4858.—*Greenhouse roof*.—I should strongly advise you not to use such a material for a plant house. It is opaque, and shuts out light. Ferns are the most suitable plants to grow in such a light, but it is found now that they need as much light as possible. The old theory of having green glass in houses in which Ferns are grown has long since been exploded. Glass is very cheap, and should only be used. You will have a sorry time with the plants by growing them under an opaque roof. Light is as essential to plants as to mankind.—C. T.

4852.—*Violets in a conservatory*.—On a sheltered border in the neighbourhood of Bournemouth, such *Violets* as the Russian, *Violeta Regina*, and *Welliana* (single), and the Neapolitan and Marie Louise (double), ought to flower more or less freely all the winter through. Strong clumps of the above, as also of *De Parne*

(double), and the Double White *Cemte Brezza* and *Belle de Chatenay*, in 6-inch or 7-inch pots, will bloom profusely in an unheated conservatory, if kept close to the glass, freely ventilated on mild days, and liberally supplied with water. The secret of getting fine plants and plenty of blossom is to plant out the rooted runners annually in April.—B. C. R.

4835.—*Begonia seed-pods*.—In order to ripen these properly, either the heat of the sun or that of an artificial character is necessary. If the greenhouse is provided with a heating apparatus, by all means get it to work at once, and with a nice genial atmosphere and not too much moisture, the pods will not be long ripening. In a low temperature, with moist atmosphere, they are very apt to decay prematurely, but enough fire-heat will prevent this. As soon as they begin to turn brown, and show signs of opening at the top, gather them off and finish them on paper, either in a sunny window or on the mantelshelf of a warm room.—B. C. R.

— Gather the pods when turning brown, and lay them on a piece of paper in a warm room; they will quickly ripen off. There will be sap enough in the pod to finish off the ripening if taken as soon as it changes colour. Lay the paper on which the pods are placed inside a saucer.—E. H.

4845.—*Treatment of "Geraniums"*.—The plants will flower all right in time, but as they are already so strong they ought not to have any liquid-manure or stimulant, and only enough water to keep the soil from becoming really dry. They must also have a moderate but not a moist warmth, with all the sun available, or they will probably not flower till the spring. If you have a heated greenhouse, remove them there, placing them on a sunny shelf or high stage, where the tops will be not far from the glass. Here, with a temperature of 50 degs. to 60 degs., and the treatment described above, they are almost certain to show flower shortly. I have always found seedling *Zonalis* bloom beautifully in the winter under suitable conditions, but they are apt to grow very tall.—B. C. R.

— The plants will not grow much during the winter. They may want repotting. From now onwards keep them on the dry side, giving only sufficient water during the winter to keep the soil just moist. Too much will kill them. Every decaying leaf should be picked off, and in spring they should bloom well, perhaps before, if assisted with a little artificial heat. Place them as near the glass as possible to prevent bigger growth. I mention this, as some stages in plant houses, small ones in particular, are far removed from the glass.—C. T.

— Seedling *Pelargoniums* have a tendency to make wood rather than bloom; therefore they should not be over-potted, but should be encouraged to make root. When thoroughly pot-bound give them liquid-manure two or three times a week. You will probably succeed better with cuttings from your seedling plants.—A. G. BUTLER.

— Keep the seedling "*Geraniums*" rather dry through the winter. Starve them a bit, and they will flower in spring.—E. H.

4863.—*A span-roofed greenhouse*.—Having tested both of the apparatus you mention, I give you the result of my observations. To question 1, I should say that you will get the most heat from a hot-air, radiating apparatus; but from a cultural point of view the warmth from it is not equal to that obtained from hot-water. 2, Yes. 3, About equal. 4, Certainly not, only the best oil obtainable should be used. You are wise in not wishing to use oil only for the purpose of keeping out frost. If everybody who requires a warmth in their greenhouse would act the same, the oil-stoves would not be so disappointing.—J. C. C.

— This is a rather puzzling question. The radiating stoves are very good and decidedly superior to the common ones in which the fumes escape directly into the atmosphere. A well constructed hot-water apparatus, however, possesses many points of advantage, and if the boiler is made on a sound principle, these are just as economical as the others. Some of the gas and oil boilers advertised I would not have at a gift, but those made by Toope are an excellent pattern, effective and economical. Of course, a hot-water apparatus is somewhat more costly than the other in the first place, but with ordinary care they last as long or longer than the radiators.—B. C. R.

4792.—*Leaky glass roof*.—It is rather difficult to advise from information given. If the glass is loose and parted from its bed it

would be better to take out and reglaze. If the top putty only is defective, and has come away from the glaze, take it off, fill the space between glass and bar with putty level with the glass. Make a pint of the following: 1 part litharge, 1 part good white lead, 1 part dried white sand; add sufficient boiled oil to make it workable, and keep it off your best coat.—J. B. R. D.

ROMAN HYACINTHS FOR EARLY FORCING.

DESPITE the fact that during the autumn and winter months we have in Chrysanthemums alone an almost unlimited supply of white flowers, there is always a scarcity, so to speak, of pure-white flowers. It is at times like these, and especially from October to January, that the pure-white fragrant spikes of these early Roman Hyacinths are so much in demand and meet with a ready sale. In their purity and fragrance they are not surpassed by any other flower during the time stated, especially when we compare the ease with which they may be grown to perfection, combined with their general utility. Another item of importance, particularly to growers of such things in quantity, is that they are quickly turned to account when abundance of bottom-heat is at command—an essential in the quick production of their useful spikes of flowers. But while heat plays so important a part later on, we must not lose sight of the equally important fact that to get the flowers early, an early start must be made in procuring and potting the bulbs. This, indeed, is of primary importance not only with these, but with all bulbous-rooted plants intended for forcing during the ensuing winter. It was very satisfactory to note the good condition of the earliest consignments. Larger I have seen certainly, but, taken all in all, the bulbs were of excellent quality. This was generally expected as a result of the good weather in May and June, a time when so many bulbs are maturing themselves, and given careful treatment from potting onwards, good results should naturally follow. If not already done, as it should be, procure the bulbs without further delay. Remember that the best quality are not only best, but cheapest, as these frequently give two and three spikes each; whereas the smaller sizes usually produce but one, and where space is limited, quality should stand before quantity. As soon as the bulbs are to hand, preparations may be made for potting them.

THE SOIL may consist principally of good loam fairly rich, but not too heavy; add to this some leaf-mould and sharp sand. The soil should be sufficiently moist at potting time to cause the bulbs to start roots at once; while if overdry, the chances are that the bulbs may still remain some time dormant, which would mean a decided drawback to their earliness. When well rooted, water may be given in plenty and that without fear. In potting I prefer to pot the whole of the season's crop at one time, or as near to this as it is possible to do it. Some prefer to pot in batches to produce successional batches of flower, but this latter can be better regulated by their introduction into heat than in any other way I know; indeed, they have a decided advantage over later potted bulbs, inasmuch as they will have made a maximum of roots, than which there is no greater or surer aid in all early forcing of bulbous plants. The later portions will, however, when treated as I have just suggested, require attention now and then to be sure that no mischief is being caused to any flower-spikes by the weight of the plunging material, and any that are pushing remove at once. In potting them, some 5-inch or 6-inch pots will be found as convenient as any, inserting as many as five or six bulbs in each according to size, hurrying them almost completely, and making them very firm in the soil. This last is needful to keep them in position, as if neglected, the bulbs will sometimes lift themselves out of the soil. When potting is completed, place them on a hard bottom of coal-ashes, and cover either with the same material or Cocoa-nut-fibre; if the former, 4 inches or 6 inches deep will suffice, but if the latter, they should be covered fully 8 inches. Unless coal-ashes are procurable that have been some time exposed to atmospheric conditions, I advise the exclusive

USE OF THE COCOA-FIBRE, and even where available

are plentiful and very cheap I prefer, as a precautionary measure, to place a handful of fibre over each pot before putting on the ashes, which may contain an amount of sulphur sufficient to mark the tips of the leaves, and thus render them unsightly. Once plunged they will be safe enough for the present, while the average rainfall at this season of the year will keep them sufficiently moist for all purposes. Where very early flowers are required, say for the middle of October or thereabouts, a small batch may be introduced into warmth in a month or so from potting-time, and placed on a gentle bottom-heat of 75 degs. to 85 degs., being covered for the time being with fresh Cocoa-fibre. It should be stated, however, for the benefit of those less experienced in these matters that these very early batches can rarely, if ever, be persuaded to produce their average length of stem. It is so with other things besides these that are what may be called overforced, but where left a fortnight or so longer produce results far more satisfactory. In those instances where early October flowers are an absolute necessity, this can only be done by sowing the bulbs at the earliest possible moment and setting them going without a day's delay. A very large number, I have no doubt, will be satisfied with getting flowers any time during November and onwards. When first placed on the bottom-heat and before being covered up the whole should receive a thorough watering, allowing them to remain uncovered during the night, placing the fibre on early next day. From this time a moist warm temperature must be maintained, and with the bottom-heat above-mentioned growth will quickly ensue. When the growths have attained a height of about 6 inches the bulbs may be taken from the fibre and stood in the same house in a darkened spot for a few days, giving a thorough watering. By degrees the foliage will assume its proper hue, and the plants may receive more light. When the flowers begin to expand, a lower temperature may be given.

CLEMATIS INDIVISA.

THIS is a strong-growing, very handsome evergreen greenhouse climber, bearing white flowers in great profusion during the spring

Clematis indivisa on a greenhouse wall.

months. It is from New Zealand, and is a very suitable plant for a large house or greenhouse wall, where a considerable space has to be covered, and where it has room to develop itself sufficiently to exhibit its natural character. It is a free-rooting subject, and requires to be planted out, as no ordinary sized pot could contain enough soil to support the growth which it makes; but in commencing with young plants it is better to grow them on for a time in pots, so as to get them well furnished with roots before turning out into a prepared border. This Clematis is very appropriate for planting at one end

of a house, and training under the ridge. When allowed to hang thinly in festoons it has a good effect, and is more fitting for being so grown than things which are not naturally calculated for extending far. As the soil in which the roots are placed gets exhausted, recourse must be had to stimulants in the shape of copious waterings during the growing season with liquid manure, and renewal of the surface-soil in the spring by removing an inch or two from the top of the border the roots occupy, and replacing it with new. When the space is filled which the plants are intended to occupy, each year, after flowering, the knife should be freely used so as to reduce the shoots within proper limits, and to allow room for the season's growth. Red-spider will, during hot weather, sometimes attack this Clematis, and should be guarded against by a free use of the syringe. Brown scale can be removed by sponging in the usual way. If white scale gets upon this, or any plant growing overhead on the roof, there is no chance for its extirpation except cutting the head close in during the winter when at rest, and dipping or washing the affected stem and remaining shoots with a strong solution of insecticide. B.

4829.—Tortoise in a garden. — A tortoise requires no food during the winter. It may be placed under cover in a box filled with hay, or in a warm, light coil in the garden, where it will be quite comfortable. I kept a tortoise for years, but it does not like covered cold. It is in a state of torpor during the winter, but regains vitality with the quickening warmth of spring. During the summer months, fresh Lettuce leaves, sops, and similar food is most available. It relishes fresh vegetable leaves.—C. T.

A tortoise does not eat anything in winter, for it takes a decided season of rest, hibernating in a snug corner, which it will select for itself. They bury themselves from 6 inches to 9 inches underground. There was an old stager in a garden where I was employed in Scotland which did not get down lower than the epaede went in digging; and had several dents in his armour made by the epaede. They wake up again to active life in the spring, and feed upon Lettuce and other green food; but they prefer Lettuce to anything else.—J. D. E.

Some years since we had a tortoise in the garden. As cold weather approached it pushed into the box-edging and hibernated. When asleep it was taken indoors, placed in a basket in a kitchen cupboard and there remained without food until spring, when his movements in the basket warned us he was ready to be put out again.—F. P.

4832.—Lemon Verbena (Aloysia citrodora).—This plant will live against a warm wall if sheltered in winter; but it is by no means a hardy plant for general planting. Even against a wall it is frequently killed to the ground in winter. In Sussex it lives out against a wall without protection, and probably it would do so in Dorsetshire. But to give a plant a fair chance it should not be planted out till the spring. Plants can be purchased at any good nursery.—E. H.

This is a fine old plant, but is not very hardy. I should advise you not to plant out until spring, as if planted out now you would have all the trouble of keeping it alive during the winter. In a southern exposure in a Dorsetshire garden it should be quite happy. Plant it against a sunny wall, and in a light, well-drained border, but cover over with a mat during very cold weather, otherwise it will most assuredly suffer; or heap coal-ashes over the roots. It is a charming old plant, its leaves as fragrant as a Lemon when bruised, and their delicate green colour is a fit accompaniment to flowers. I saw a good plant near London that had been out for two or three winters; but the plant was in a very warm, sheltered, sunny spot, and nestling almost underneath a crooper. You could purchase a plant at any good nursery.—C. T.

Phyllocauli blooming twice in one year.—I have two large plants now in bloom, bearing seven and eight large flowers respectively. They blossomed before in May this year. I know this is very unusual. I attribute it to using liquid-manure too freely. The plants are strong and healthy, and flowers fine and well developed.—W. N. G. L.

4815.—Hot-water pipes.—The pressure on your hot-water pipe is probably caused by air. Obtain a slight rise from the top pipe on your boiler to the point where it needs to return. Fix here an air-trap or pipe. Get a fall from here right back into the boiler. Make the leaky joints good and you will have no further trouble.—J. B. R. D.

ROSES.

SEASONABLE NOTES.

As many of my readers may like to raise their own Roses, or at any rate increase their stock of some favorite variety, they will do well to procure a few Rose-stocks as seen as possible. Manetti, seedling or cutting Briers, De la Griffonaise, and other stocks may be purchased by the dozen or hundred from almost all nurserymen. Some little while back it was not usual for many trade growers to part with their stocks to the amateurs; but I am happy to say that almost all of them now recognize that the greater interest an amateur takes in his garden, whether it be by propagating his own plants or not, the hotter customer he eventually becomes to the professional grower.

DWARF STOCKS should be carefully looked over, and all dormant eyes cut out from the base. If not done closely now, there will be great risk of suckers forming during the next two seasons; but if this little precaution be taken, and the Rose-huds are inserted sufficiently low down when the time for that operation arrives, the risk of suckers is reduced almost to nothing. Hodge Briers should also be collected and planted at once. Country readers can procure their own if they choose, but the task of removing Briers from a hedge is very far from an easy one, and requires tact, with a large stock of patience. They may be bought from five to eight shillings per hundred, the usual price being a penny each. It is a good plan to purchase mixed sizes at a cheaper rate, and then trim them to your own liking. No stock is more generally useful than the short hedge Brier, and it is much wiser to keep the plants as dwarf as your requirements will allow. Care should be taken to trim off the coarsest of the Brier roots before planting. I have known them to be planted in almost as rough a state as when collected; this is unwise for more than one reason. Firstly, the roots are apt to decay; secondly, an alarming amount of suckers are almost certain to be produced; and thirdly, the plants move very easily. My Briers are trimmed almost as close as if the main stem was only removed, with a slight heel of the older root attached; and I find they then produce better roots, while suckers are naturally reduced to a minimum. Plant the dwarfs about 2 inches above the collar of their roots. In dwarfs that are obtained from cuttings, I frequently find a considerable number of roots issuing from the sides of the stems. These should be trimmed off, it being only necessary to leave these at the bottom. The side roots are caused by the stock cutting having been planted so much deeper than is at all necessary or advisable for the stock previous to being budded upon. It may also be well to state that

SPENDING BRIERS need be no larger round than a knitting-needle, as they will swell quite large enough for budding by the time they are wanted. If larger than this, they often get too coarse for the smaller buds, and do not suit such Teas as Mme. de Watteville, Mme. de Cusin, Ma Capucine, and other slight-wooded varieties. The Briers obtained from hedges need planting 6 inches to 9 inches deep, and should be trodden up firmly. It is of the utmost importance that these be got in during the present month, any delay after November often meaning the difference of a bad instead of good take. Whatever state the Briers may be in, it will do no harm to immerse them in water for an hour or two previous to planting. Having spoken of rooted stocks, let us turn for a short time to the preparation of a few for another season. Both Brier, Manetti, and De la Griffonaise, also such strong growing Roses as Polyantha simplex, Dundee Rambler, and others, will all root freely if cuttings are made as follows: I may also note that the Polyantha stock and cutting Briers are decidedly the best for all-round purposes. Choose the growth of this summer and cut it into lengths of 9 inches. Make the lower cut just beneath an eye, and trim out all of the eyes below the two or three near the top of your cutting. Now insert them quite three-parts of their length in sandy loam, and after making them firm, cover over with a little rough litter. This is also much better if not left later than the end of the present month. If you have no wood of the various stocks I have named, there is a method

why a few shoots from any extra strong-growing Rose should not be sacrificed to the same end, and the resulting plant will make excellent foster roots for any Rose you may choose to work upon it. P. U.

4831.—**Rosess pegged down.**—The wood of those which bloomed during the past summer should be cut away as far as possible without removing the long maiden growth of this season. My own plan is to do so early in the autumn, and then draw the remaining growth up to a stout stake, thus preventing any whipping and swaying by wind. Whether protection be needed or not will depend a great deal upon the position they occupy and the locality. If exceptionally cold or low I would protect with a few pieces of bracken tied around and among the branches upon the approach of severe weather. By pruning and tying up as I have described there is a good opportunity offered of applying manure and working the ground between the plants. Woods can be cleared off, and the whole got ready for next year's pegging down.—P. U.

When Roses have been pegged down they form roots from the portions under ground, and require no tying up in the winter. It is a good plan to place a good mulching of manure over the roots and around the stems of the plants, especially if they are Teas.—J. D. E.

4855.—**Rosa "Jean Ducher."**—The manner in which your plant behaves is characteristic of this variety. It is only now and again that we get a season when Jean Ducher is good out of doors, and although the warm, dry summer just passed might have been thought most suitable to so double a flower, it has not been so with me. If it refuses to open with you, dig it out and plant Françoise Krüger, a Rose of somewhat similar colour, and always opening well. Jean Ducher is grand under glass, but its petals are too thin in texture and far too numerous to open well during an ordinary summer.—P. U.

This is a magnificent Rose when it opens to perfection, but alas! in most seasons for one good bloom twenty buds fall to the ground or rot on the plant in a vain attempt to expand. I should not think of recommending this Rose to any amateur; but if "E. S." would like one that has a similar variety of lovely and indescribable tints in the flower, that grows with amazing vigour, flowers with equal profusion, and never fails to open every bud it produces, filling them with lavish fragrance, such a Rose exists in Dr. Grill. It is not an exhibitor's Rose, and will rarely be seen at the shows; but all who care for Roses and can grow the most refined and most beautiful of all the Teas should be sure of having Dr. Grill. Its flowers are like lovely sunset in the wealth, richness, and variety of tints.—A. H.

I have silently borne with the same behaviour in this Rose as you complain of, because I thought that in some way my treatment of it was not quite right—either the soil did not suit it or the position was too cold; but seeing that the plant grew freely and showed plenty of flowers which never opened I thought it might improve. But now "E. S." in the adjoining county of Devon finds it behaving the same, even when given a wall, I fear it must be classed as one of those Roses that cannot always be depended upon to open its flowers properly. This is the more provoking, because in some cases it is quite satisfactory. The only consolation I can get out of its behaviour is that there are others like it. I can never get in my own garden a good flower of Gobault or Camoens. Amongst the H. P.'s, La Francoise, Violetto Bouyer, Queen of Quoons, and Heinrich Schultheis behave pretty much in the same way. The best advice I can give to "E. S." with regard to Jean Ducher is that to discard it and plant Catherine Mermet in its place.—J. C. C.

4841.—**Standard Rosess.**—As the situation is bleak and cold, and the soil stiff on a clay bottom, I would certainly not plant standards. Plant Hybrid Perpetuals worked on the seedling Brier. I consider the seedling Brier the best stock, not only for Hybrid Perpetuals, but also for the Tea-scented Rosess, which are more perpetual than the others. Of course, in such soils draining is indispensable, and I would advise raising the ground where the Roses are to be planted 6 inches or even a foot above the surrounding level of the garden. I practice

this very successfully, not only with Teas but also Hybrid Perpetuals.—J. D. E.

The Brier stock is certainly the best for your soil, but tall standards are not adapted for a bleak situation. You had better get dwarf plants on the cutting Brier stock, and choose such varieties of Hybrid Perpetuals as Magna Chartre, Earl Dufferin, Merveille de Lyon, Charles Lefebvre, Mrs. Jowitt, Paul Neron, Marquis de Castellaine, Mlle. Eugénie Verdier, Captain Christy, Mme. Charles Wood, John Hopper, Gustave Piganeau, Etienne Levet, Dupuy Jamain, Alfred Colomb, and Antoinette Ducher.—J. G. C.

You ask for the names of standard and bush Roses suitable for a very bleak place. I may say at once that standards are almost hopeless in such a position. If you must have them in this form, choose from the following: Baronne Prevost, Gloire de Dijon, Françoise Krüger, Jules Margottin, Henry Bennett, Captain Christy, Homère, and La Reine. As for dwarf or bush Roses, there are so many good varieties that I could not possibly name them. In addition to those advised for standards, the following will make a fair collection of various colours: General Jacqueminot, Baroness Rothschild, Ulrich Brunner, William Griffiths, Madame de Tartas, Mrs. John Laing, Dupuy Jamain, Marie van Houtto, and Bonlie de Neige.—P. U.

I should certainly not advise you to grow standard Roses in a bleak, cold spot. They are never good in such positions, and high winds play considerable havoc with them. It would be far better to confine the kinds to bush plants, which are not so influenced by weather. I have noted the following kinds as good in such places, and they would form a very interesting selection. Of Hybrid Perpetuals Duke of Connaught (deep crimson, a very good flower), Dupuy Jamain (crimson-cherry colour), John Hopper (of a lilac tone), Mme. Clemence Joigneaux (rose shade), Mme. Gabrielle Luizet (rose also, touched with a silvery tone), and Merveille de Lyon (white); whilst of Teas, very good are Françoise Krüger (a charming flower, with its copper colour, flushed yellow and salmon), Jean Ducher (one of the finest of the Tea section, and exceptionally beautiful this year), the Bourbon Mme. Isaac Perière (carmine-rose), Mme. Lamhard (peppery-rose, but very variable in colour), and the well-known variety Homère. Such favourite sorts as Aimée Vibert I have seen do well in cold localities, and it makes a beautiful standard, and, of course, the old Gloire de Dijon may be mentioned as one of the hardest of climbers. You must plant at once. November is the best month of the whole year for Rose-planting.—C. T.

4831.—**Climbing Rosess in a bleak place.**—If you have a south aspect to your house, such Rosess as Reine Marie Henriette, Climbing Victor Verdier, and Cheshunt Hybrid will no doubt be sufficiently hardy, and they are of different shades of red. Lemarque (white) will do on the same aspect. For the west side you may select Gloire de Dijon (fawn), and Sir Joseph Paxton (rose). None but very hardy Rosess are likely to do well on the east side. These may be Félicité Perpétuelle, Dundee Rambler, and Williams' Evergreen.—J. G. C.

Here again, similarly to your query 4841, you are wishing to grow Roses in a spot altogether unsuitable for them. "A very bleak place; nothing to shelter whatever" does not sound very promising for Rosess. A house wall so exposed as yours cannot possibly do climbing Roses well, and I would strongly advise you to try something else—say Virginia Creeper, Ivies in variety, or something else equally hardy. I willingly name a dozen of the hardiest climbing Rosess I know: Gloire de Dijon, L'Idéal, Aimée Vibert, Gloire de Bordeaux, Charles Lawson, Sir Joseph Paxton, Emilie Dupuy, Madame Burard, Kaiserin Frederich, Reine Marie Henriette (rod), and Dundee Rambler (white).—P. U.

The Ayreshire Rosess (white and bush or pink) and the Bourneville varieties (crimson and rose) will be found better adapted to such a position than any others, and are tolerably sure to do well.—B. C. H.

4861.—**Rose Souvenir de la Malmaison.**—You need not hesitate to plant this Rose on the Brier stock, as I have known it to live for many years as a standard, although hard pruned every year; but the more freedom you give the growth, whether on its own roots or the Brier,

the longer it will live, and the more flowers it will produce. A friend of mine who grows Roses for the Bristol market cuts hundreds of this Rose every autumn from dwarf plants that get no other pruning but the removal of the growth with the flowers, and he has a line of plants many yards long.—J. C. O.

— This will do very well on the Brier-stock. I saw several splendid bushes in Essex this year all on this stock, and also on own roots. It is a very fine old Rose.—C. T.

— You may take it that this grand old Bourbon Rose will do well upon the Brier-stock. Although it does well on its own roots, it is by no means so essential as Doan Hlo states. I have some old plants on own roots, Manetti, and Brier, and I will defy anyone to choose between them. If planted at a proper depth—viz., a couple of inches below the collar of the plant, they can go off upon their own roots if so inclined, and will thus obtain additional support.—P. U.

4810.— **Treatment of Roses.**—Your Roses have behaved similarly to many more during the remarkable season we have just passed through. As they are growing so strongly, I conclude they are varieties suitable for pegging down in the spring, and I would advise your retaining the long growths you speak

shoots one-third, and then peg the whole of the growth down to the soil, allowing a space of 9 inches between each shoot as they rest on the ground. I expect this is the first year after planting. If so, it is not unusual for the plants to make vigorous growth if they are well attended to, and it is not likely that they will grow quite so strong another year. If you cannot see your way to peg down the long growths you had better shorten them back one-half now, and in the spring leave the straggles 15 inches to 18 inches long, and the weak ones half that length.—J. C. O.

FATSIA (ARALIA) SIEBOLDI.

It is surprising how much effect and how much pleasure may be obtained from very slender materials, if only they escape being commonplace, and it is some compensation for many fruitless struggles to win success when one realises that a garden with a marked characteristic may be more satisfactory than mere variety. In many parts of the kingdom there is such an abundance of material that the very fact of their being so great a mixture somewhat confuses the effect, and so we lose the thing we sought for. Some years ago, when riding by the sea in

only satisfactory alternative to the too ubiquitous Aucuba, also a native of that quarter of the globe. It is much to be regretted that, owing to this Fatsia soon suffering both from sun and frost, it has not been considered sufficiently hardy for general seaside planting, and no one who gives it a trial will repent his experiment. Iris foetidissima, a native evergreen Iris that grows abundantly on the south coast, and is well known there for its handsome capsules full of bright-orange berries that glow in the winter sunshine, thrives and fruits just as freely under cultivation on the north-east coast, and makes a very pretty edging to a bed or plot of Arelia. Used as a hedge to keep off salt wind from low-growing plants, it is especially welcome as being ornamental as well as useful. There is a variety with clear silver variegation running all down the leaves, which is very pretty, particularly in the shade, and as it never berries like the wild form, one loses nothing by planting it in such situations. This variety is useful also for winter bedding, and looks extremely well with some dark shrub behind it and Lilac Primroses in front. There is also a very handsomely variegated form of the Fatsia, with creamy-white blotches and irregular edgings, which is larger and more massive in foliage than the type, and stands better in the open than that does; but it is not so healthy in deep shade, so that there is a place for both. Combinations of these materials with shrubby Veronicas and yellow winter-flowering Jasmine are exceedingly bright and pretty in mild seasons, and give a winter effect as pleasing in character as more extended plantations. E.

OUR READERS' ILLUSTRATIONS: Aralia Sieboldi. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. O. Major, Holmwood, Paignton, Devon.

of, and treating them in this manner. The method of pegging down has been described in GARDENING so often that there should be no need of further instructions. However, as several will doubtless be asking questions relating to this system of cultivation, I will give a short note upon it in season; probably early in the spring. At present I would recommend you to secure the long shoots from awaying and injuring one another during the coming season.—P. U.

— As the Roses have made such very strong growths, this would show that they have really good soil underneath them; however, it is usual for Roses to make strong shoots in the autumn, and to make them flower well the following season I would advise that these strong growths be not cut down too closely. It will be a good plan to give the surface of the ground a dressing with some manure. Old hot-bed-manure does well; this protects the Roses from the effects of frost, which often kills Tea Roses down to the manure, and if intense will injure the Hybrid Perpetuals.—J. D. E.

— If the plants are dwarf ones, you have an excellent opportunity to test the merits of the pegging-down system of Rose growing, and I advise you to adopt it. Some time in the months of December or January shorten back the long

Japan, not far from Yokohama, I noticed how well this Aralia, or, as is perhaps more correct, Fatsia Sieboldi, grew under the shade of trees when so exposed to the sea winds that they themselves were much out by storms. As a window-plant that will endure much hardship, we all appreciate its value in England, but as an outdoor plant it has not as yet its proper value, for it is generally planted in some sunny and sheltered situation where it will not thrive. On returning to England I took the first opportunity of planting any old stumps that had been exhausted by ill-nage indoors under the shade of trees, and, spite of some of the intensely severe winters, I was pleased to see that they pushed out healthy new leaves that withstood both winter storms and the nipping frosts that they had to endure. In a garden where Hollies not unfrequently drop most of their leaves after severe gales, and refuse to live under trees where fully exposed to the east blast, where no Conifer, Laurel, or Yew will even exist through two winters, is just the place where this leathery-leaved shrub should be planted. It enjoys a strong and moist soil, and dislikes the full exposure to sun and frost as much as the most delicate lady could do; but planted in shade more or less deep, the more of its handsome, Fig-like leaves is quite striking, and it is most welcome, as being the

bulbs of various kinds, as Daffodils, should thrive if the soil is something better than builder's refuse.—C. T.

Two good garden flowers.—Two of the best hardy plants for the garden are Rudbeckia speciosa and Erigeron speciosum. I have had the former in bloom from the summer until now, and the plant is very compact in its growth, the flowers produced on sturdy stems, and deep yellow, with an almost black disc. It is very hardy, free-growing, and makes a dense mass of bloom of this very effective association of colour. The Erigeron is just as free, the flowers of a light purple colour, borne in clusters, and charming to cut for the house. It keeps up a succession over a long season. For gardens near large towns both these are suitable, and are useful for amateurs. Good colonies of them in large gardens give beauty to bed or border during late summer and autumn.—V. C.

A good variegated plant.—One of the best variegated hardy plants for town or country gardens is the variegated Dactylis (D. glomerata variegata), which grows very fast, and makes a dense tuft of leafage. The leaves are narrow, quite Grass-like, and almost white, but striped with green. A few bits I put in last spring grew into quite large plants before the end of summer, so that it can be broken up again readily for increase of stock.—T. C.

FRUIT.

LATE PLUMS.

LATE Plums do not receive nearly sufficient attention from growers of all classes. I think the best late autumn Plum in cultivation is Coe's Golden Drop, which will keep good for weeks if gathered before it is overripe. I have had good fruit of it for dessert in December by keeping it in a

Fig. 1.—Italian Prune (Quetsche d'Italie).

dry room. It grows and fruits freely on both east and north walls. I have had no experience of it as a standard, but the tree has a good constitution, and would, no doubt, do well in that form. The Italian Prune or Quetsche d'Italie (Fig 1) is also another very excellent late dessert Plum, having somewhat the same characteristics as the preceding, with the exception of colour, which is a deep purple. The flesh is yellow and very rich, rendering it a most desirable variety to cultivate. The Blue Imperatrice is a Plum but seldom seen, but it bears freely generally, and if allowed to hang until the fruit shrivels, it is delicious. Coe's Late Red is another late Plum worthy of every consideration. The value of the Yellow and Black Bullaces (see Fig. 2 on this page) is often overlooked by those who have space for standard trees in garden or orchard. These Bullaces hang a long time, are amazingly prolific, and make most excellent tarts, &c. B.

4837.—**Hardy fruits.**—Get the holes prepared at once, and if any builder's rubbish or other rough stuff could be easily obtained dig the holes out at least 4 feet in diameter and 2 feet deep; place 9 inches of rough stuff in the bottom, ram it down, and raise a little mound where each tree is planted. In cold, heavy, clay land the thing to guard against is deep planting. In such land if there is a depth of 15 inches to 18 inches below the surface for the roots to work in a further 6 inches or 8 inches can be obtained by forming a mound above the surface, and the trees under such conditions will do better than if thrust deep down in the land, where the temperature will be lower, in consequence of being beyond the influence of solar heat. As regards varieties, the following generally succeed under unfavourable conditions. If possible, I should plant the Apples on the broad leaved Paradise, and have some, at least, of the Pears on the Quince. Apples (kitchen): Keswick Codlin, Stirling Castle, Rohioville Seedling, Warner's King, Red Hawthornden (or Yorkshira Beauty), Stone's Apple, Bramley's Seedling, Lane's Prince Albert, Batty Geeson, Tower of Glamis, and Northern Greening. Apples (dessert): Beauty of Bath, Irish Peach, Yellow Ingestrie, Cox's Orange Pippin, King of the Pippins, Braddick's Nonpareil, Mannington's Pearmaio, and Allen's Everlasting. Pears: Beurré Superfin, Bon Chrétien (Williams'), Doyenné du Comice, Louise Bonne of Jersey, Marie Louise, Pitmaston Duchess, Fertility, Souvenir du Congrès, Beurré d'Amalouis, Beurré Diel. Plums (kitchen): Cox's Emperor, Diamond, Ashbourne's, Pood's Seedling, Orleans, Prince Egglebert, Victoria, and Cluster Damons. Dessert Plums: The Czar, Monarch, Transparent Gage, Belgian Purple, and Old Gage.—E. H.

4788.—**Pears on a clay soil.**—Pears, as a rule, do well on clay soils if they are worked upon the Pear-stock; but good cultivation is necessary, and the land must be drained. A novice in the culture of fruit-trees may ask what is understood by good cultivation? Draining, if it has not been done, and also providing an outlet for the water. Next loosening up the soil to a depth of 18 inches; but keeping the

subsoil in its place, merely forking it up, and keeping the 9-inch subsoil in its place, and the top soil stirred up with a digging fork. If the soil is in good condition no manure would be required to be worked into it; but after the trees have been planted a dressing of manure should be placed around the roots. This keeps the moisture about them, and in various ways promotes their growth during the winter. When the subsoil is poor, and the surface soil light, the Quince-stock is best, as it is surface rooting, and the trees can be fed by surface dressings of manure. I had charge of a garden for many years where the subsoil was nothing but gravel and the top soil very light; but by putting some clayey loam around the roots to give the trees a good start I obtained exceedingly good fruit from all the varieties which thrive on the Quince-stock. A few were double grafted.—J. D. E.

4848.—**Peaches and Tomatoes under glass.**—If the Tomatoes are thinly trained. Peaches would on the back wall. Success would in a great measure depend upon the management. The dangers to be guarded against would be red spider on the Peaches and mildew on the Tomatoes. These evils may be avoided by careful watering and judicious ventilation.—E. H.

— It may be just possible to obtain a fair crop of Peaches on the back wall of a lean-to Tomato-house, but I have never seen them do much good in such a position. Of course having the full light (or nearly so) until the end of July makes a great deal of difference, and on the whole it may be worth a trial. Procure an early variety, such as Alexander or Hele's Early (the last is far superior in point of flavour), so as to get the fruit ripened before the trees become shaded.—B. C. R.

4860.—**Plum-tree not bearing.**—It appears somewhat strange that such a healthy tree should not bear something, especially as it blooms so well. All I can suggest is to root-prune it, cutting any strong, deep-lying roots right through. This should be done at once. If this fails you might try cutting it back hard, and grafting or budding some of the shoots with a reliable variety (the present tree may be of an inferior kind, or possibly a worthless seedling), but the worst of Plums is that if pruned hard they generally bleed or gum badly, disease sets in, and you lose your tree.—B. C. R.

4849.—**Large Apple-trees.**—If the middle of the trees was sufficiently fruited with bearing wood after you had taken away the centre branch, it is very clear that they would soon get too much crowded again if you left any of the young shoots you allude to. You had better cut away at once the whole of the young growth on the out-back branches. Lord Suffield is an Apple that is very liable to get crowded with growth, especially if the soil is not very good, and then the fruit is small, and very often badly deformed.—J. C. C.

4844.—**Canker in Apple and Pear-trees.**—This usually appears upon trees that are planted in unsuitable soil. If the roots run into a wet cold subsoil canker is almost sure to follow. To prevent it the roots should be encouraged to grow near the surface, and if the soil needs draining see that it is done, and as soon as canker shows upon the young trees lift the roots up nearer to the surface, and put some good garden soil amongst them. If the growths and branches have become badly cankered, the diseased portions must be cut out, and in most cases they will come right again.—J. D. E.

— Some varieties are more subject to canker than others, but as there are plenty of free-bearing kinds not subject to canker if fairly treated, the sorts predisposed to canker should be got rid of. Canker is mostly found where the soil is wet and, consequently, cold, and where the roots are too deeply buried; deep planting generally leads to canker, and it has been found that by lifting a cankered tree and laying its roots near the surface the disease has been stopped, and the tree has afterwards made healthy growth.—E. H.

— Surely "Beta" must be wrong in attributing the unsatisfactory condition of the Apple and Pear-trees to canker. In the first place Pear-trees are not nearly so much subject to canker as Apples. Then "Beta" speaks of the lumpy excrescences as the result of

canker. If that is so, it is a form of canker that I am not acquainted with, although canker, as I know it, is painfully evident on a Ribston Pippin Apple-tree I have. If I am not very much mistaken, it is the "American blight" that has attacked "Beta's" trees, and it is these insects which cause the lumps on the hrenoeae. There are some hopes of getting rid of "American blight," hot cooker, never. Touch each of the affected parts with paraffin-oil, applied with a small brush. This may be done at once, but as the insects are not so much in evidence at this time of the year as in the months of July and August, the trees must be carefully gone over at that time next year and the same remedy applied. Anything like painting the branches must, however, be avoided, or it will certainly kill them. A light touch with a brush that has been dipped in paraffin will kill every insect it touches. If the insects are numerous, the trees will want going over three or four times from June to September. A safer remedy in inexperienced hands is a solution of 6 oz. of Gishurst Compound to 1 gallon of water, if applied in the same way as I have advised for paraffin.—J. C. C.

4833.—**Paint for fruit-trees.**—There is a good deal of misconception about painting the stems of fruit-trees; evidently many persons do it without knowing the reason why. To paint the stem of a tree that is free from insects and lichen, as many do, is doing more harm than good, because the material used has a tendency to stop up the pores in the bark and so check growth. Here, however, is a description of the ingredients used by many fruit-growers in Somersetshire and Devonshire. It is used for the purpose of destroying Moss on the stems. Three parts fresh slaked lime and one part fresh collected cow-manure, which is mixed together to the consistency of thick paint, and applied with a fairly soft birch or Heath broom. The materials are mixed in a wheelbarrow and applied to the trees at once. This has the effect of keeping the stems of the tree quite clean, but, strange to say, the large branches are left uncoated for, although frequently covered with a mossy growth.—J. C. C.

ANNUAL FLOWERS DURING THE PAST SUMMER.

AMATEURS who have been so disappointed with the annual flowers this year must not think them valueless on that account. This has been a sorry year for them simply through the exces-

Fig. 2.—Black Bullace.

sive drought, which played havoc with other things than annuals. Such plants as Zinnias have done remarkably well, but the majority of annuals, especially Sweet Peas, have distinctly failed. There is no doubt that bad management is responsible for much of the mischief, and the summer is blamed when really the fault is with the sower. On badly prepared ground

it is hopeless to get a sturdy growth, and by sowing three times as much seed as necessary the young seedlings are crowded up, and become leggy and weakly. Much good seed is lost through sowing too deeply, especially fine seed which needs only a light covering of soil. Very pleasing this year has been the well known Canary Creeper, which is delightful to train over a trellis or to hide unsightly spots.

AUTUMN-SOWN SEEDS of the hardier annuals give excellent results, but, of course, the plants make good growth when the seeds are sown in the spring, if the sowing is not delayed beyond the proper time. Let each plant grow to fullest perfection, and after the seedlings appear above the growth thin vigorously to enable each plant to develop to its utmost capacity, which it will do, and surprise those who sowed thickly with a dense profusion of flowers and sturdy spreading growth. A great point in hardy annuals is to select varieties which bear flowers of distinct colour, and this is more necessary now, as some of the newer additions are of magenta shades, which are abominable, producing a dead, unpleasant effect. There are many decidedly coloured annuals, the flowers white, crimson, and rose, or shades of the same, as a rule, and a bed of the White Godetia, for instance, is of great beauty. Those who are sowing now should think of this. This leads me to say that in distinct blocks the several varieties are best seen, applying the idea of massing to annuals as to hardy perennials to get rich and beautiful effects, or the seed may be sown as a groundwork to other plants. Roses and Mignonette go happily together, and amongst tender annuals a bed of Crimson Celosia is richly attractive. One of the prettiest effects I saw this year with annuals was a mass of Malope grandiflora and its white variety growing amongst some Apple-trees.

ANNUAL AND BIENNIAL PLANTS grown well are capable of giving much pleasure at comparatively little cost, if the proper varieties are selected. The Sweet Pea, for example, has undergone within the past ten years much improvement, both in size of flower and so in variety of colouring, without sacrificing its bloom or sweet fragrance. A few of the finest I made note of in the collection in the Chiswick garden this year were Captain of the Blues (very rich blue), Mrs. Sankey (white), Mrs. Gladstone (a lovely pink, delightful for cutting), and, of course, the rich self forms, as scarlet, white, and pink, which are effective in masses. In the case of very new varieties, of which there is possibly very little seed, the wiser plan is to sow in pots, planting out into well-prepared ground at the end of March, taking care that before they are put out the growth is thoroughly well hardened. This treatment helps the plants, and they give a finer return in flowers. What I have already said about thick sowing applies strongly to the Sweet Peas, which are invariably sown too thickly, the result being that the haulm becomes crowded, weakly, and the display of flowers poor. The once common style of sowing annuals in clumps in the borders or in long lines is not the best to show off the individual beauty of the respective varieties. Annuals are often fleeting, looking shabby when thus treated after a comparatively short time, but when used amongst Roses the effect is delightful. White Asters, for example, planted amongst such dwarf Roses as the China Cramoisie-Supérieure being decidedly pleasing, or the colouring may be reversed, white-flowered Roses with Crimson Asters. The great thing is to get away from set rules, which were the chief feature in carpet-bedding, and annuals are a happy style of plant to use. I saw once a large bed of Standard Roses made in a sense pleasing by smothering the surface soil with Poppies, quite an easy thing to do and costing little. At the foot of Standard Roses, which are seen in many gardens, sow Mignonette, or some other annual, and extend the plan in every possible way. I alluded to Roses, but it is not, of course, necessary to restrict the association of annuals to these. In a Surrey garden a large Araucaria imbricata occupied a rather conspicuous position, and sentiment only prevented its destruction, but the bad effect of the unhealthy lower branches was in part obviated by sowing French Poppies, which gave a wonderful variety of colour. Phlox Drummondii is a delightful flower for sowing with Roses

or herbaceous plants, and with a little foresight there need be no dulness in the garden or unsightly corners. I saw this year a dry, sunny bank smothered with Nasturtium in such varieties as Empress of India, these throwing up their flowers well above the profusion of leafage.

In thus associating Roses and other hardy plants with annuals, it is necessary to take care that the annuals are not overdone to the injury of the plants by being permitted to crowd amongst them, whilst there is no need to prepare the soil especially. Mixtures, as a rule, are not good unless managed with extreme taste, and, therefore, it is always better to keep the various kinds quite apart—a row of White Sweet Peas, for example, having a much prettier effect than several sorts mixed up together. Another point is not to try things because they are rarely seen: It would be, of course, folly to plant a garden with annuals only; but I once saw a public place in which they were used to the exclusion of practically all other things. This was at Scarborough, where, on the western cliffs, was a garden of annuals sloping down to the sea, the walks winding in and out, and the whole sheltered from the full blast of the ocean. The months in which this garden was required in full beauty were August and September, and at that period

Waterer's Double-flowered Cherry (*Cerasus Watereri*).

It was a blaze of colour. A complete representative of annual flowers, which, when in beds of irregular shape, as in this case, are charmingly free and natural. V. C.

FERNS.

4854.—Malden-hair Ferns.—Your query does not afford much information. It is possible you have kept the soil too wet, or they do not like the constant change of temperature. I could have advised better if I knew the names of the Ferns, as perhaps the sickly one is more delicate than the others. During the winter Ferns are not so fresh looking as in spring or summer, and require much less water, neither is shade necessary. The sickly aspect may be due to a want of sufficient nourishment in the soil through getting pot-bound. Keep this plant in the greenhouse, or send its name; one can advise better. There are many kinds of Maiden-hair Ferns, and some require much more heat than others, and are more delicate.—C. T.

—These are not good Ferns for room decoration; they feel the change from the moist warmth of a greenhouse to the dry stuffiness and half light of a room. You would do better to grow a few *Pteris tremula* or *Ribbon Fern* (*Pteris aquilina*) for indoor decoration.—A. G.

TREES & SHRUBS

SHRUBS FOR FORCING.

A GREAT many shrubs forced into bloom are employed for greenhouse decoration during the spring months, and where they are required for this purpose and are not grown in pots, they should be lifted early in the autumn—just before the leaves fall. Treated thus, the plants get partially established before winter, whereas if potted late in the season they may flower just as well, but the blooms have not so much substance and do not last so long in beauty. In selecting plants for forcing, only those that are of good shape, with well-ripened shoots and plenty of flower-buds, should be chosen. Where a number of shrubs are forced every year it is a good plan to have a couple of sets, giving each set a season to recoup itself. Some people keep the shrubs for forcing in pots, others plant them out, this last method giving the least trouble. Many of the Ericas are suitable, as they possess the advantage of forming a dense mass of fibrous roots, and they can be lifted and potted at almost any season of the year without injury. Besides the endless forms of Rhododendrons and hardy Azaleas, there are two varieties of Andromeda—*floribunda* and *japonica*—that flower beautifully under glass, as also do the different *Kalmias* and the pretty little *Xenobia speciosa*, of which there is a variety (*pulverulenta*) with bright silvery foliage, which under glass is remarkably striking. The little *Erica carnea* or herbacea, which in mild winters commences to bloom in the open ground soon after Christmas, is very bright and cheerful in the greenhouse for the first two months of the year. A great many rosaceous plants are also forced into bloom, but the majority of them will not bear so much shifting about as the Azaleas and things of that class, although they are extremely beautiful when in flower. Of these may be mentioned the Almonds, Peaches, *Charicia* (the one here figured, Waterer's Double-flowered, is very beautiful), and Thorns, especially the double-blossomed kinds, as they last longer in bloom than the single forms.

CYDONIA JAPONICA and its numerous varieties that flower so early are also available for the purpose, and so is *Pyrus Maulei*, whose peculiar orange-red blossoms supply a very distinct shade of colour. *Pyrus Malus floribunda*, too, I have also seen forced into bloom, and very pretty it is in the shape of little standards, with long, graceful shoots. *Spiraea Thunbergi* is very pretty, and can be forced into flower readily. It has little white Hawthorn-like blossoms, which are borne on slender, arching shoots. *Prunus triloba* and the double-flowered form of the dwarf, much-branched *Prunus sinensis* are both very easily forced, and remarkably showy when in bloom. *Deutzia gracilis* is one of the first plants to be obtained when shrubs are needed for forcing, as it readily lends itself to such treatment. Besides this, the double-flowered form of *Deutzia ornata* is very beautiful, but it cannot be had in flower so early as the single form. Lilacs are commonly forced, and give but little trouble provided suitable plants are obtained. For small bushes the Persian Lilac is the best, but both the double and single-flowered forms of the common kind may be forced just as readily. *Hydrangea paniculata grandiflora* is now largely grown in pots and brought into Covent-garden Market in considerable numbers during the season, but it does not naturally bloom till the end of the summer or in the autumn. *Berberis*, especially *viridissima*, may be grown into neat bushes, and they are valuable for flowering under glass, as blooming naturally early in the season, they will expand their blossoms in the temperature of a greenhouse. *Berberis stenophylla*, though rarely used for the purpose, will do well forced, as also will *Styrax japonica*, a neat growing shrub with slender branches, from the underside of which depend its pure-white, drooping, bell-shaped blossoms.

STAPHYLEA COLCHICA must be included in the list, but though very pretty, it is difficult to get good bushes of it. The Snowball tree (*Viburnum Opulus sterilis*) will flower well if not brought on in too high a temperature, and good sized plants should be chosen for the purpose. I have succeeded very well in forcing some of the hardy Magnolias—viz., the Yulan (*M. campanulata*), *M. Liliiflora*, and the pretty double-

flowered *M. stellata* and *Halleana*. As the Magnolias greatly dislike to be shifted, the plants are grown in pots and plunged outside during the summer, when they set their buds for the next year's display. *M. stellata* is especially valuable in this respect, as it retains its neat, compact habit for years and flowers freely every season. *Weigela rosea* and some kinds of *Ceanothus* will flower well under glass, though they are but seldom employed for the purpose. Another subject rarely seen is the *Laburnum*, whose drooping clusters of golden blossoms are

Fig. 1.—Broad-leaved Saxifrage.

very effective. One thing to be borne in mind in the case of forced plants of all kinds is that when the flowers are over they should not be turned out-of-doors at once, but should be gradually hardened off. In the case of *Azaleas* that are forced every year they go to rest earlier than those that are in the open ground, and consequently they may be had in flower earlier in the spring. H.

4846.—**Transplanting Laburnums.**—You could not have a better time than the present for transplanting these things. They ought not to require much pruning, but, if necessary, you can either trim now or in the spring. Any good garden soil will suit them. Put a little well-rotted manure in round the roots when you plant, and do not forget to heel them well in. More trees and shrubs are lost through neglect in this particular than from any other cause.—A. G. BUTLER.

—You can do the work now—this is, in fact, the best time—or from now until this spring. Do the transplanting carefully. It is not necessary to have any special soil, and do not go hacking the shoots about with a knife; let the trees develop their own characteristic beauty. A *Laburnum* is very beautiful, especially in spring, when its branches are laden with golden blossoms. In transplanting, take care to get a good ball of roots with the trees, and make a hole sufficiently large to receive them. Spread out the roots carefully, and work in a little of the finer parts of the soil amongst them. Tread firmly, and make the soil also firm as you proceed. If necessary put in a good stake, to prevent the trees rocking about in the wind.—G. T.

—Transplant now, and do what pruning is required in spring. Long straggling shoots may be shortened back now.—E. H.

4836.—**Planting Poplars.**—The Lombardy Poplar is the only variety of this tree that is at all suitable to make a hedge only 6 feet in height. It is better adapted for a height of 20 feet than 6 feet. If you decide on using it you had better get plants about 4 feet high, and cut off the tops of the leading shoots as soon as they reach the required height. You may plant at once, and if you want a hedge quickly you must not set out the plants more than 2 feet 6 inches apart. *Opulus Lawsoniana* would be very suitable for the height you want, and the plants would not cost but a few shillings more, and you would have an evergreen hedge in three or four years.—J. C. C.

—I suppose the Lombardy Poplar is meant, as this is the kind usually planted to form hedges. If plants which have been grown thinly, so as to feather down to the ground, are selected, and planted 4 feet apart, there will be a hedge of the required height at once, and all that is required is to tie and trim it into shape. Plant at once.—E. H.

The Siberian Crab.—This is very beautiful this year. It will grow well near large cities, and is suitable for small gardens, at least gardens where the larger growing tree are out of place. The tree is graceful in growth, leafy, pretty when in bloom, and very bright through

the winter, as it is laden with small, brightly-coloured fruits, which make good preserves. This year the Crabs are fruiting usually freely owing to the warm summer. Such kinds as *Fairy*, and others which are not always so free, are carrying good crops of the pretty fruit. The *Fairy Crab*, or *Apple* as it is sometimes and more aptly called, is a firm, crisp, juicy, and pleasant flavoured fruit, worth growing only on that account. The *Siberian Crab* is the best of the family for small gardens, and a tree on the outskirts of the lawn is pleasing to look at through the whole year.—E.

HOUSE & WINDOW GARDENING.

CHRISTMAS ROSE BUDS.

AMONG the many ornamental aspects of the early Hellebores, whether growing or out for indoor enjoyment, perhaps the beauty of the flowers in the bud stage is hardly enough noticed or appreciated. The flower is bold and beautiful in all states, but is singularly graceful when drooping in early bud and in its younger half-expanded bloom. This is most noticeable in the varieties that are pure-white outwardly, and whose buds are long and slender. Our engraving (Fig. 2, p. 567) draws attention to the grace of bud form of this noble winter plant, both as growing and as a little handful gathered for room decoration, grouped with a leaf or two of the Broad-leaved Saxifrage (see Fig. 1), whose warm winter tints set off the pure-white flowers charmingly. The leaves of the Christmas Rose are too precious to cut, and in many soils they are not in good order at blooming time. It is worth while to grow some plants of the common *Helleborus foetidus* (easily grown from seed and doing well in any out-of-the-way corner) for its fine supply of handsome leaves to accompany the Christmas Rose flowers.

A good room plant.—A plant one does not see very much in rooms is called *Ophiopogon Jabnan variegatum*. It is a very strong grower; the leaves creamy-white and green, the variegation not spotty, but boldly marked. Such plants are useful to mix with other things, green-leaved, and it stands the heat, varying temperature, and neglect that life in a room entails. Of course, there should be no neglect; but it is so, and that is the reason why there are so many complaints of window and room flowers failing. The *Ophiopogon* produces also very pleasing deep-hine flowers in spikes, which show well against the variegated foliage.—E.

4859.—**Out blooms for the house.**—I presume you mean hardy flowers. *Achillea* the *Pearl*, *A. mongolica*, or *A. ptarmica* fl. pl., are all useful for cutting, blooming in the summer. The first and last have pure-white double flowers, those of *A. mongolica* longer, but single. All are really first-class border kinds. *Anemone japonica alba* for late summer and autumn is indispensable. Then also amongst white flowers have the *White Snapdragon*, very charming in the summer, *White Canterbury Bells*, *Chrysanthemum Leucanthemum duplex*, *White Pinks* (June), *Funkia grandiflora* (September), in a warm, dry spot; *White Everlasting Pea*, *White Lily*, *Lupinus polyphyllus albus*, an easily-grown plant for the summer; *White Pheasant's-eye Narcissus* for the late spring; *White Pyrethrums*, but of various colours, the pink ones are very pleasing. Other plants of service to you are *Anemone coronaria*, *A. falcons*, *Michaelmas Daisy*, especially the more graceful varieties, such as the varieties of *Aster lewis*; *Delphiniums*, *Paeonia*, *Pentstemon*, which bloom from summer through the autumn; *Primula japonica*, *Erigeron speciosum* (pale-purple), *Cornflowers*, *Centaurea coccinea* in variety; *Iris*, particularly the German kind; the *Blue Salvia patens*, *Wallflowers*, *Coreopsis lanceolata* (yellow), *Rudbeckia speciosa* (autumn), *Gaillardias*—plant in spring in light soil; *Perennial Sunflowers*, particularly such graceful kinds as *Helianthus argyleus*; *Iceland Poppies* (yellow and white), and various kinds of spring-flowering bulbs.—G. T.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner and will appear in due course in *GARDENING ILLUSTRATED*.

ORCHIDS.

INDIAN CROCUSES (PLEIONES).

THESE appear to have been blooming very freely with "Mr. J. Woodhouse," for he says he has ten panfuls of them (in three different kinds) all in blossom. Now, "Mr. J. W." wants to know if he can grow any other kinds, and what he is to do with them after the blooming season is past? Well now, what I should like to impress upon him and my readers is that they should try to keep these Pleiones from blooming too soon, because this will defer the growing time, and it will also tend considerably to increase the strength of the bulbs, and thus will give finer blooms, and these in greater quantities. The plants flowering now should not be excited with too much heat, so as to induce the new shoots to push too forward; therefore, I like to give them a slightly cooler place immediately after blooming, and to keep them in this position some three weeks or a month before putting, but they must be carefully watched during this time to prevent any injury befalling them. If, however, the young growths seem inclined to come away they should at once be potted and be placed in more warmth. Now, these plants grow naturally under such conditions that we cannot think of imitating. However, they succeed well under cultivation. The pots or pans must be exceptionally well-drained, and the soil used for them should consist of good fibrous peat and *Sphagnum Moss*, mixing in a little dried cow-manure. This should be made sandy. This soil should not rise up quite to the rim of the pot, for if left below the pot's rim there is better chance of the bulbs getting a larger supply of water during the growing season. This water supply must be given moderately at the first potting, or the season's growth may be spoiled through the roots rotting, but as they continue to grow and to root more liquid may be given. When about half grown many people give them an occasional supply of liquid-manure, but I do not like the application of manure-water at all to any Orchids. When the bulbs have fully formed, less water must be given, and as the leaves begin to turn yellow and to fall off the supply must be gradually diminished until it nearly ceases, only just enough to keep them in a plump and sound condition is all that will be required until the flowers begin to show up, when a little extra moisture will be necessary. Some like to suspend them in hanging-pots or pans; but I like better to stand them upon a shelf in the Cattle-house, close to the glass, and to shade them from the hottest sunshines, because their leaves are thin, and they quickly lose their beautiful green colour if too fully exposed to the influence of that luminary, so the plants should have a thin shading upon them during the middle of the day. The following kinds may be grown by anyone having the accommodation of an ordinary stove-house; indeed, I have seen the species grown and flowered in a much finer manner in a mixed plant stove than I have ever seen them in an Orchid-house pure and simple, and I have frequently remarked that the Orchids when grown specially by themselves do not make such a good atmosphere in the house as do some plants of other tribes when mixed with them.

P. ARTHURIANA.—This plant was named by Reichobach in honour of the late Mr. Arthur Veitch, and it comes from the mountains of Burmah, although by some it is considered to be a variety of *P. maculata* from the Khasia Hills, and in various other parts of Northern India. In general appearance it is somewhat smaller than *maculata*, and the flowers are also of a more diminutive size. The petals have a marginal band of lines of rosy-purple, and the front lobe of the lip is bordered with purple.

P. HOOKERIANA.—This, although introduced here, is the rarest of the species, and it occurs at a greater elevation than many of the kinds, and the leaves remain green until after the flowers have fallen. These are rosy-purple, with a much lighter lip, which bears sundry blotches of brownish-purple.

P. HUMILIS.—In this we have a very handsome kind, which also grows at considerable elevations. The colour is soft lilac, the lip being fringed with long hairs. It is white, spotted with purple.

P. HUMILIS TRICOLOR is a variety sent out, if I mistake not, by Mr. Wm. Bull some few years ago. It differs from the typical plant by having the lip more or less blotched with orange.

P. LAGENARIA.—This is one of the most beautiful flowers in the whole genus; the sepals and petals are rose coloured, more or less striped with deep-lilac or purple. The lip is beautifully frilled by numerous raised lamella, the colour being purple and white, streaked and blotched with red.

P. MACULATA.—Another beautiful kind, having white sepals and petals, the white lip being streaked and splashed with rich purple, and bearing several raised lines or fringes.

P. REICHENBACHIANA.—A larger and stouter growing plant, found growing at considerable elevations in Burmah; the flowers, too, are somewhat larger than many of the other kinds. These are rosy-lilac, with purple spots, and a few fringed plates on the lips.

P. WALLICHIANA.—This is a large flower, the sepals being much broader than the petals. These are a dark rosy-purple, the lip about the same colour, with a fringed edge. There are a few more kinds known, but the above are the chief species in cultivation, and all may be readily obtained, saving P. Hookeriana, which, I think, is still very rare in the collections of this country. **MATT. BRAMBLE.**

THE SMALLEST CATTLEYA (CATTLEYA LUTEOLA).

This is a very pretty Orchid, which I am asked to say a few words about by "J. Holmhury," who brought some plants of it from Para; this locality is not its natural home, but it would appear to have become naturalised and acclimatised in the gardens of Para, for it is found growing in the trees in the open air, and it likes the situation amazingly. It is a continuous grower, and it is seldom without flowers during the whole year. This Cattleya appears to have been originally introduced in this country by the Messrs. Rollisons, of Tooting, who then had a famous nursery business at that place, and they had received the plants from the banks of the River Amazon, where it grows in great profusion upon the shady side of the trunks of trees that grow near, and from whence the plants which now are so prevalent in Para originally came. It appears to be the smallest species of the genus Cattleya known, and it produces pale yellow flowers which have the side lobes of the lip in some varieties lined with reddish-purple, and the front lobe of the lip is slightly crisp and toothed. It is not a showy plant, and it does not attract by its perfume, for it is quite destitute of scent. The slender peduncles bear several flowers which each measure some 2 inches across. These, being of a soft citron colour, render it very attractive, and moreover they last a long time in perfection if properly cared for and kept from the effects of the damp. It is a plant which has gone out of fashion considerably, for now that we have such plants as C. Warroqueana from M. Linden, and the true old C. labiata from Mr. Sander, and the superlatively beautiful C. Bowringiana, introduced into this country by the Messrs. Vetch, there are very few that would deign to look upon the modest little flower of C. luteola, but it is an exceedingly interesting plant, and worthy of note because it is the smallest flowered species known. It should be securely fastened upon a block of wood with a little peat fibre and Sphagnum Moss, and it should be well supplied with water through the growing season, and it is best not to dry it at any time of the year. But much less water will be necessary in the drier months after the flowers are past. The best method of watering this plant through the summer season is by taking it down every other day and dipping it, and it may be sprinkled over with the syringe when the other plants are done. It may be grown through the summer months in the cool-house, but in the winter-time it likes the extra warmth obtained in the Cattleya division. **MATT. BRAMBLE.**

OUTDOOR PLANTS.

TULIPS AND THEIR CULTURE.

It is now about the time to plant out the late Tulips, and those who intend growing these beautiful old-fashioned flowers should have previously prepared the ground for them. The old growers used to make up their beds with very great care, sparing no expense if they thought that the flowers could be improved in quality. Very seldom, indeed, was a Tulip-fancier satisfied with the natural soil of his garden by merely digging or trenching such garden soil as he had, and adding sand or manure as it might be required, he could have obtained a delightful bed of Tulips; but his fancy was to dig out this soil to the depth of 18 inches, and afterwards fill this space up with decayed fibrous loam, leaf-mould, manure, and sand, thus entailing an unjustifiable expense. This Tulip will grow in any good garden soil which has been well worked to the depth of at least 1 foot, and a good dressing of manure applied to the beds. This should be dug in to the depth of at least 6 inches. The right thing is to see that this soil is well exposed to the air by frequent turning over, and this ought to be done when the weather is dry. During wet weather it is much better to leave the ground alone; but after rain, and when the surface is dry, it ought to be stirred up with a digging fork lightly, or it may be run over with a Dutch hoe. This preparation of the ground is merely trenching it in the first place, and exposing it to the air up to the time of planting by hoeing it or forking it over. I had an idea that the Tulips did not do well after Carnations, and am rather confirmed in this belief by reading a paper on the Tulip in "Gossip for the Garden," published in 1857 by the late Mr. Richard Hoadly, of Stapleford, in which it is stated that a Tulip grower in Cambridge attributed the loss of his collection to planting them in the soil wherein his Carnations had been grown the previous season. For several seasons I planted the Tulips on ground which had grown Carnations during the summer, and I never was satisfied with them when thus planted. My idea was that the Carnations not being removed until October, there was not time enough to get the ground into good condition for planting by the first week in November, especially if the weather was stormy and the ground wet. If much snows in producing fine blooms is expected, the preparation of the ground should be seen to as early as possible in the autumn, so that it may be got into a nice friable condition. I have frequently experienced the disastrous effects of

BADLY PREPARED SOIL not only for Tulips but also for Gladioli, as these classes of bulbs are more sensitive to bad soil than any other bulbs known to me. When the soil is not in good condition some finely sifted loam from the potting-bench, which is found in most gardens, may be used to put around the bulbs; if the siftings are from heavy loam some coarse sand may be added to it. My plan is to draw a deep drill with a hoe, and fill it up with this dry, fine soil; and with a trowel plant the bulbs to the required depth, pressing the dry and fine soil under and over the bulbs. This system of planting should be adopted whenever the weather is wet at the time of planting, and in truth the soil is more often in a wet than in a dry state in dreary, dull November. It was a very absurd practice of the old growers to delay their planting until a certain date in the second week in November. This seems akin to the old superstition of sowing and planting when the moon was in a certain stage. About the end of October, if the Tulip bulbs are examined, it will be found that they are bulging out a little at the base; this is caused by the roots beginning to push out, and the sooner they are in the ground after they have arrived at this stage the better. A careful, sensible cultivator will look at his bulbs and plant them at once, when the roots show signs of moving; if planting is delayed until the roots have pushed outside their brown covering, it is almost impossible to get them into the ground without injuring the bulbs. Some effort must be made to get the varieties which have a tendency to grow to the same height into the same rows. The old plan, which I do not think can be improved upon, was to plant seven rows in a bed 4 feet wide. The

lowest plants in the centre row, and the next tallest in the two rows next to it, and the dwarfest Tulips were planted in the two outer rows. The Tulips were sold as first row, second row, &c., up to the fourth or centre row flowers, and the classes were mixed, beginning with the rose-coloured varieties, flamed or feathered, and planting alternately with them the bizarres and hybloemens. To those unacquainted with the show or amateurs' Tulips, I would remark that they are arranged in classes—viz., bizarres, hybloemens, and roses, and these are subdivided into flamed and feathered varieties. Another class is the "breeder" or self Tulip. "Why breeder?" someone may say. The name arose in this way: Nearly all the seedling Tulip flower for the first time in a self-coloured state—that is, the roses and hybloemens are rose, scarlet, purplish, maroon-purple, or lilac-purple, with a clean white base. The bizarres are red, crimson, or chestnut-coloured, with a clear, deep yellow base after a few years, sometimes as many as ten years. The self Tulip will break into flame or feather, and if the bulbs have been distributed before they break the process may take place in different gardens the same season, hence arises the word "strain." One grower in Kent may get a break, another in Sussex, and yet another in Surrey; and thus we read of Hardy's strain, Horner's strain; and the late Mr. Barlow was celebrated for his good strains, which he used to purchase. Some of the

ROSE AND SCARLET TULIPS in the self state are beautiful exceedingly, and one would rather that they did not "break" either into flame or feather. But there is no accounting for it; it is a freak of nature, and the result cannot be hastened or delayed by any process of culture. In January the Tulip plant appears above ground, and this need to be the signal for the fancier to get out his apparatus for covering, the more simple being a series of iron hoops bent over the bed at intervals of 3 feet or 4 feet, and mats were thrown over the hoops whenever bad weather set in. A dry frost is not injurious, nor does wet injure bulbs or plants; but frosts after rain are certainly to be guarded against, for the axils of the leaves hold water, and when this is allowed to freeze the delicate outer coating is ruptured, and disease will sooner or later follow in the wake of these frosts. The bent hoop and mat coverings will not do to protect the plants when in bloom. The best arrangement is a light canvas covering

Fig. 2.—Buds of Christmas Rose. (See page 506.)

that will admit light, but will also throw off the water from rain, hail, or snow. I have seen an unprotected bed of Tulips in flower covered with snow, and also bent double by sharp frosts so late as May. Therefore, if Tulips are to be of any use, or give some degree of pleasure to their owner, it will be necessary to protect them. To save all the trouble and mess of temporary shading, one of the best growers has built a glass structure to cover his Tulip-beds; it is glass to the surface of the ground, and amply provided with ventilation; and it is an uncom-

4800.—**Fence behind border.**—The wire-netting will do very well if the situation is a sheltered one. But Clematis and other creepers are not so successful generally as an open fence as an open one, the reason being the wind cuts through often with considerable force. A draughty place is not suitable for anything of a tender nature.—E. H.

mon treat to a Tulip fancier to see the handsome foliage of the Tulips under glass, spotless, immensely large, and glaucous, as if silvered. The glass-roof is an effectual protection against all weathers. I have seen these Tulips grown in flower-pots; but they were not altogether satisfactory, and I would certainly not recommend their culture in this way. As border flowers they are in their place, and make a rich and varied display at but little cost. J. D.

4847.—Sowing perennials.—There is not much gained by sowing perennials at this late season. Many of the seeds would be likely to perish during the winter, and very few of those which grow would flower next summer. Gaillardias might flower late in summer, but Delphiniums, Campanulas, and Columbines will hardly do so. Better sow the perennials in March or April in a nursery bed, and fill in the border next year with annuals.—E. H.

— With the shortest and darkest days of the year fast approaching it is out of the question now to think of sowing seeds of perennials with the possibility of their making much progress towards flowering next year. If the query had appeared in the month of June "Perseverance" might then have realized his wish. I should advise relying mostly upon annuals for next year, and at the same time raise a stock of perennials for planting when the annuals have finished blooming. Even among annuals "Perseverance" will find types belonging to the families that are particularly desired. For example, among Lupinus nothing could be prettier than a mass of *Lupinus nanus*, which is easily obtained by sowing the seeds where the plants are required. It grows about 18 inches high, has long spikes of blue and white flowers, which come in succession for a long period. *L. Hartwegi* and *mutabilis* are other good annual forms. Perennial Delphiniums are not to be thought of for next summer, but annual types of the Larkspur are a host in themselves, rich in variety of habit and colour. Of *Campanulas*, *C. carpatice* raised early is a perennial kind that might be relied upon to bloom abundantly in late summer and autumn. It occurs in blue and white forms, and is easily raised from seed. Among annual kinds *C. macrostylis* is curious and pretty, a beautiful thing not often seen, and *C. Lorenzi* with blue flowers grows freely from seed. Gaillardias raised early would give a wealth of bloom if strong when planted out. A charming annual I can strongly recommend for a sunny bed or border is *Sphenogyne speciosa*. It should be sown where it is to bloom, and the plants thinned so that each has nearly 2 square feet of ground to spread on. The plants hide the ground with a mass of graceful foliage and flower in wondrous profusion. The flowers are Daisy-like, about as large as a penny Lunum, and orange yellow in colour, with a black base forming a ring in the centre of the flower. When open in the sun it has a brilliant effect, and if allowed room it goes on growing and blooming for at least three months. Iceland and Shirley Poppies, too, sown in spring, would give abundance of bloom in a variety of pretty tints.—A. H.

4857.—*Tropaeolum speciosum*—This is hardy, and may be left alone. I like to see it best wandering about through shoots, or sending its vermilion-flowered racemes through a hedge. It would do well, I should think, against a trellis, and requires a good position and a rich, moist soil. If to be planted out, the spring is the best season for this, and lot it alone to go its own way. It is beautiful hanging over a ledge on the rockery, or mounting up into a shrub. I wonder how a splendid creeper is not more grown in gardens. There is an impression it is tender, but such is not the case; but it must have moisture.—C. T.

— This is a hardy plant, and if occupying a fairly sheltered position will be quite safe. The summer was too hot and dry to suit it, and the plants, at any rate born in the south, made but little growth, as you say, until recently. This *Tropaeolum* enjoys a cool, moist, and shady, yet not too much exposed, position, and a light rich soil, and then grows and blossoms profusely with a minimum of care.—E. C. R.

4806.—*Convolvulus minor*.—Dwarf Nasturtiums are the same thing as *Tropaeolum*. You cannot have anything better for a smoky garden, but the tall kinds frequently do better than the dwarf, partly because

they are of stronger growth and do not need such good soil, partly because they can run up more into the light and air. *Tropaeolum Lohbianum* is a very showy (climbing) variety, and *T. Fireball* is also excellent, indoors or out. Minor *Cucurbitals* will flower fairly well; but *Phlox Drummondii* and *China Asters* will give splendid masses of rich and varied colouring, and *Cornflowers* and *Chrysanthemum coronarium* (annual) will both do well and be found useful for cutting.—B. C. R.

CHOICE LILIES.

LILIUM BROWNII.

This origin and early history of this Lily appear to be obscure, for by some it is considered of garden origin, while by others it is regarded as a native of China and Japan. This I should consider very doubtful, for among the vast numbers of Lilies sent here from Japan during the winter months I have never found the true *L. Brownii*, though the nearly allied *L. odorum* or *jeponicum* is imported from that country in quantity. *L. Brownii* is a remarkably beautiful and striking Lily, belonging to the tube-flowered section, forming the *Eulirion* group of Mr. Baker. The flowers, which are large and massive in texture, are ivory-white within, but heavily tinged with chocolate on the exterior, especially if they are in a position fully exposed to the sun, as where heavily shaded the marking is less pronounced. The bulbs of this are very distinct from those of any other Lily, being narrow at the base, widening towards the centre, with a peculiarly flattened top, the entire bulb being tinged with reddish-brown. Its flowers have an agreeable perfume, which is not so powerful as in many other Lilies. The foliage is very dark-green, while the stem, especially towards the base, and the leaf-stalks are tinged with purple. When the blossoms are fully expanded the dark-brownish anthers stand out very conspicuously against the ivory-white petals. *L. Brownii* is, especially when dormant, very impatient of an excess of moisture, as the scales of the bulb are liable to decay just at their base, and sometimes the bulb, which at a casual glance appears to be sound enough, will fall to pieces on being handled. Though by no means a rare Lily, it must be regarded among the more uncommon kinds, so like *L. Leichitini*, *Hansouii*, *neigherense*, and others, it always commends a good price. It is thought to be named in honour of Mr. F. E. Brown, a nurseryman of Slough, near Windsor, in whose catalogue it was published about fifty years ago, so that it is not new. The only Lily with which *L. Brownii* can be confounded is *L. odorum*, known also as *L. japonicum*, and in auction catalogues, during the winter frequently called *L. japonicum Colchesteri*. Though a good deal of confusion has existed between the two the points of difference are so well marked that there is really no excuse for it, as commencing with the bulbs those of *L. odorum* are whitish, and in shape more like those of the *longiflorum* section, that is broader at the base than in *L. Brownii*, while the centre is somewhat raised. In all stages the stems of this are green, the leaves much broader and thinner in texture, while they are throughout of a dull pale-green, very different from those of *L. Brownii*. The flowers, too, are somewhat shorter and rather more widely expanded at the mouth, while the exterior is much less deeply tinged than in *L. Brownii*. This Lily is said to have been introduced early in the present century, but was soon lost to cultivation, and it is only within the last few years that the constant importations from Japan have made it comparatively common. It is, however, not a good traveller, the bulbs being liable to decay just at the base, as mentioned in the case of *L. Brownii*. On this account freshly-imported bulbs need to be closely examined before purchasing them. It is somewhat difficult to understand the specific name of *odorum* being applied to this Lily, as so many other members of the genus are quite as fragrant. The above two Lilies may be easily grown in pots.

H. P.

4888.—Poultry destroying garden.—You must not kill your neighbours' wife, as they can sue you for their value, but having given them warning, you can send them a demand for damages to say reasonable amount, and if the money is not paid, take out a County Court writ, and you are almost sure to get the money.—B. C. R.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on the reverse of the paper only, and addressed to the Editor of *GARDENING*, 37 Southampton-street, Covent-garden, London. Letters on business should be sent to the Postmaster. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be given, and those who reply would do well to mention the facilities to which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

4876.—Roses for pegging down.—What are the best kinds of Roses for pegging down over a sunny bank?—B.

4877.—Moving Apple-trees, &c.—Is it too early to move Apples and other trees, to leaves on which are still green?—E.

4878.—Outdoor plants.—Which is the better time to transplant perennials with a view to forming a herbaceous border, now or in the spring?—H. P. H.

4879.—Pegged-down Roses.—Will "J. C. O." kindly say what are the best kinds for above, and the best time to plant them in warm garden, west coast?—H. B.

4880.—Fuchsias from seed.—I wish to know how to grow *Fuchsias* from seed, as I have a prize plant which I cannot rear a slip from, and I am afraid I shall lose it.—A. WATKIN.

4881.—Foliage Begonias.—Will someone kindly give me the names of a few of the best foliage Begonias with their colours, and also where they could be obtained?—J. B. R. P.

4882.—Treatment of Rhubarb.—I should be grateful for information respecting the best treatment for Rhubarb at this season to produce abundance of stalks next spring?—M. C.

4883.—Plantains, &c. in a lawn.—Will someone please be so good as to say what should be done to get rid of large numbers of Plantains, Dandelions, &c., in a lawn?—WOODLANDS.

4884.—*Ostrowskya magnifica*.—Would someone kindly inform me what kind of soil and what situation best suits *Ostrowskya magnifica*? Any hints for its culture would be welcome?—F. E. THOMPSON.

4885.—A Virginian Creeper.—Will "A. H." who gives particulars of a new Virginian Creeper called *muralis*, kindly tell me where such plants can be procured, and if best to plant in autumn or spring?—M. C.

4886.—*Primula obconica*.—I have a splendid lot of *Primula obconica* in greenhouse, and I am told they are very poisonous plants, and dangerous to grow. I should like an opinion on that?—CONSTANT READER.

4887.—Destroying ants.—Will someone kindly give me the best mode of destroying ants? They are in an out-house adjoining the kitchen. I have tried paraffin oil, but it only drives them to another place.—R. M.

4888.—Violets in winter.—Should the runners be cut off Neapolitan and Marie Louise Violets in winter? They have been out all summer when the plants were in the open. The plants are new in a frame.—PETERIC.

4889.—Semi-double white Ivy-leaved Pelargonium.—Is there a semi-double white Ivy-leaved Pelargonium as good as *Mme. Crousse*, also a lilac-tinted variety? If so, should be glad of names of such.—O. N. P.

4890.—Pteris not thriving.—I have a specimen plant of *Pteris major* in a 12-in. pot. It has not done well this year. It will require potting early next. What kind of compost suits this family best? It is about five years' old.—J. B. R. P.

4891.—*Chrysanthemum M. G. Grunerwald*.—Refer to *GARDENING* of 7th October, page 430, will "J. G. W." kindly tell me where cuttings can be obtained? My efforts to secure them since the above date having been unsuccessful.—J. L. R.

4892.—Treatment of Dianthus.—Will any person kindly let me know how I should grow Dianthus? I want to have a large bed next year of mixed colours. Is there any difference between the Indian, Japan, or Chinese Dianthus?—ENGLAND.

4893.—Eucharis and Amaryllis.—May I keep these in a Cactus-house, night temperature, 55 degs to 60 degs, and day, 65 degs to 70 degs, for flowering? Should water be freely supplied, and when may they be expected to flower?—W. N. G. L.

4894.—Mealy bug on a Tausonia.—My *Tausonia* is infested with mealy-bug. Will someone kindly advise a remedy—cheap and effectual? Syringing is not practicable, as I have flowering plants underneath. Is there any other method of destroying the filthy pest?—O. N. P.

4895.—Trees and shrubs.—Will "A. H.," who answered question No. 4783, in No. 704, kindly tell me where I can procure plants of the *Ampelopsis* miracle mentioned by him? I have enquired for it of several florists without success. Is it the same as *A. japonica floggi*?—H. P. H.

4896.—Camellias losing their buds.—Will anyone kindly inform me the cause of the buds on expanding, but having only one or two open, and then dropping 60 degs, and the temperature of house is, night, from 55 degs to 60 degs, and day, 60 degs to 70 degs, kept moderately moist at night, but not in a moist heat.—W. N. G. L.

**THE NEW TUBULAR
OIL HEATING STOVE**
(HOT WATER AND STEAM)
FOR CONSERVATORIES, POULTRY HOUSES, AVIARIES, &c.
Superseding Coal and Coke Furnaces.

The introduction of this Stove marks an important advance in the method of heating Conservatories, Poultry Houses, Aviaries, &c. It supersedes all existing systems, particularly the old and uncertain one of furnaces with the necessary stoking at all hours. It is simplicity itself, and, like simple inventions, is most efficient. As will be seen by the illustration, the Stove is made upon the principle of a boiler, constructed on the tubular system, but they differ from any others in that the tubes are heated partly by hot water and partly by hot air and steam. The hot air and steam tubes become hot five minutes after lighting the burner, and the hot-water tubes soon after. The ordinary pipes are fitted with a Hinks's Kingdolphin Duplex Burner with raising arrangement for lighting. The largest have special heat-giving burners. Stoves 5 ft. 4 in. long and under are supplied with *hard* tubes; when over that length is required, loose tubes are supplied to any required length, which can be fixed by simply screwing to the firebricks supplied. There is an outlet with windmill provided for carrying off waste products, so that for Conservatories, Poultry Houses, &c., these Stoves are absolutely unnecessary and they contain, moreover, a Vaporising screw for keeping the air properly moist. For efficiency, economy, and cheapness these Stoves are unrivalled. It is important, when writing for information as to sizes necessary, to give all the information possible as to the dimensions of the conservatories or greenhouses required to be heated, with particular care as to aspect, connection with house, &c., and a rough sketch is always of assistance.

RICHARD EVENS, 43, BAKER-ST., LONDON, W.

THE STOURBRIDGE HEATING APPARATUS FOR GREENHOUSES, CONSERVATORIES, &c.
Most economical and efficient. This apparatus has attained great popularity. Made at our own foundry and under our own supervision. Before ordering elsewhere, send for Heald Bros. List, giving full particulars, free by post.
J. & W. WOOD,
Birmingham Street Foundry, STOURBRIDGE.

ROSES.

ROSES FOR SHOW.

There have been several queries in GARDENING recently that have referred to the above heading, I thought a few notes upon the subject might be welcome. The first point should be the securing the varieties capable of producing a bloom with the qualities an exhibition flower is considered to need. There are many good roses for general culture that are not capable of throwing a show bloom, or at least do so very seldom. As a guide, I name twenty-four H.P.'s that are likely to produce a large percentage of exhibition flowers, provided the plants are grown as I will endeavour to describe later on. H.P.'s; A. K. Williams, Alfred Colomb, Camille Bernardin, Charles Lefebvre, Comtesse d'Arford, Gustave Figueau, Honoré Vernet, Mme. Gabrielle Luizet, Marie Beaumont, Maurice Bernardin, Mrs. John Laing, Princes of Waltham, Prince Arthur, Suzanne Marie Buissonville, Victor Hugo, General Jacqueminot, Baroness Rothschild, Duke of Edinburgh, Duchess of Bedford, Prince Camille de Rohan, Marie Verdier, Louis Van Houtte, Etienne Levet, and Dupuy Jamain. These should be aided by the following good Teas: Anna Ollivier, Catherine Mermet, Comtesse de Natchillur, Ernest Metz, Edith Clifford, Inventive Flora, Madame Hoste, Niphetos, Souvenir d'Elise Vardon, Souvenir de S. A. Prince, Souvenir d'un Ami, and The Bride. One Bourbon, Madame Isaac Periere; and three H. Teas in Caroline Testout, La France, and Viscountess Folkestone will make up a list of very reliable varieties, and with the exception of former Vernet, Duchess of Bedford, C. de Nadaillac, and Souvenir d'Elise Vardon, all are also good for general culture; so that I can strongly recommend the above collection. A very generous treatment, with considerable attention, is necessary to secure well finished blooms. The pruning needs to be harder, quality instead of quantity being the object. Immediately the buds are visible, all but the centre one need removing. Unless this be done very early I would leave the buds to help the appearance of the bloom. Some few judges do not like to see a "truss" where "blooms" are specified in the schedule. My own taste goes for a more natural truss, the surrounding buds greatly improving the stand in my opinion. A high state of cultivation without coarseness is the great desideratum. There is also much art in cutting and choosing the blooms, some varieties needing to be cut very much younger than others, if they are to travel well and be in a uniform state when staged. I would advise staging being left until the exhibition ground is reached, but by all means arrive early. Good Moss, clearly-written labels, and taste in arrangement helps the exhibit very much. Many things have been tried in the water in order to make the flowers last fresh for a longer period, but I have found nothing better than fresh water (hard preferred) and cutting off the bottom of the stalk with a sharp knife. If the

flowers are left in water for any time, especially if the latter is not perfectly clear, the pores of the stem are soon choked with impurities, and the bloom fails. The smallest portion cut off leaves a free course again, and it is often very surprising to note the difference in a bloom so treated. The art of exhibiting ran only come from experience, but I trust these few notes may be of some little nil to beginners. P. U.

ROSE W. A. RICHARDSON.

FROM paragraphs appearing now and again in GARDENING it seems that the above Rose does not always turn out to the satisfaction of those who plant it. I have a bush which has yielded me a quantity of good button-holes, although only planted on the 18th of October last year, in a heavy brick earth loan on a subsoil full of flints. A good-sized hole was dug out and made much deeper than was required to take the roots; the bottom portion of the soil was returned after having been mixed with a little decayed manure and road-grit. The remainder of the soil taken out was lightened by the addition of road-sweepings. The roots of the tree were carefully spread out by hand over the bottom of the hole, now partly full of the returned soil, mixed with decayed manure, top soil or so in contact with the roots being only soil and road-grit, the remainder of the soil, lightened by the addition of road-sweepings, returned, and all trodden down firm. A stake or two to the principal branches must not be omitted, and as cold weather approaches thrust a handful or two of straw or horse litter into the heart of the Rose so as to protect the collar from frost. About six inches of the highest shoots were taken off at planting time, and a few frosted pieces removed in the spring. The flowers are cut with good long stems down to firm wood, and they have been assisted with a few waterings of sulphate and nitrate of soda in weak solution, to which they quickly respond. Mulch heavily in hot weather, and keep a look-out for earwigs. Any results as to pruning, so as to secure the greatest number of buds, and cultivation under glass, either in pots or planted out, will be acceptable.

G. H. W., West Brighton.

4879.—**Pegged-down Rosses.**—The best kind of Roses for pegging down is the strong-growing Hybrid Perpetuals, although for rather a large bed such vigorous-growing Teas as Gloire de Dijon, Mme. Bernard, and Mme. Lambert do very well. The kinds of H.P.'s to be avoided are those which make short, sturdy growth, like Merveille de Lyon, which we may accept as the type of those not suitable. On the other hand, we may choose such as Charles Lefebvre, Duke of Teck, and Magna Charta as admirably adapted to the purpose. Some good growers amongst those loving light or rose-embowered flowers will be found in Ulrich Brunner, Mme. Gabrielle Luizet, Duchesse de Vallombrosa, M. Nonan, John Hopper, Mlle. Eugénie Verdier, Hippolyte Jamain, Etienne Levet, and Jules Margottin. Some good red and crimson flowers will be found in the following: General Jacqueminot, Mrs. G. Dickson, Eclair, Earl Dufferin, Alfred Colomb, Dr. Andry, Marie

Charles Wood, and Marshal Vaillant. With regard to planting, you had better get it done at once if the weather continues open.—J. C. C.

—In reply to query 4876, I give a few names of suitable varieties; but all free growers are suitable. As to the best time for planting, by all means let it be done as soon as possible. You will find it better to prune your plants rather harder than usually advised for strong growers, as the wood, not being upon established roots, will be unable to carry many blooms the first year, and still produce good growth for the succeeding summer. After the first year pruning will consist mainly in cutting out the older wood and thinning out the weakest of summer growths.—P. U.

4902.—**Marchal Niel Rose.**—The Rose is in just the condition it would be in after careful management. The lower leaves falling is quite natural to it at this time of the year. The long shoots will flower at every eye their whole length if the wood is well ripened. To secure this latter condition you must keep the house well ventilated both by the top and bottom ventilators, and only give fire-heat to keep out frost for the safety of any other plants there may be in the house, as the Rose itself would be better without fire-heat up to Christmas unless the frost were very severe. I find I have to allow a period of ten weeks to get this Rose in flower by the beginning of March. For the first six weeks the forcing must be very gentle; in fact, it must be slow until the flower-buds are formed, or the young shoots will continue growing instead of forming flower-buds. I used to commence fire-heat about the 20th of December, but it was such an anxious time, preventing the young shoots growing on, and the temperature had to be regulated with such nicety to get the flower-buds to form, that I now wait until the advent of the new year before commencing forcing. Some growers cut off the soft tops of the long shoots, but I never do, although at the present time I have plenty of them over 20 feet long. I start forcing with a temperature of 50 degs., rising to 60 degs. when there are a good many flower-buds to be seen.—J. C. C.

—I have little doubt that your Roses are in a house of mixed subjects. If so, they will commence growing in ample time to produce bloom at the period you desire. The lower leaves turning yellow is only the result of your rods ripening, and unless the growth of last summer is matured, you will fail to get a good crop of bloom from it. You might stop the points of growing rods, if they seem inclined to push too freely, from the tip, instead of breaking from below. You will not get bloom from the end of long rods, these being produced from side or lateral growths upon the 8-foot shoots you mention.—P. U.

4876.—**Roses for pegging down.**—A sunny bank, such as you describe, is one of the finest aspects for this style of Rose-culture it is possible to have. All strong-growing varieties will do, but it is best to choose those which produce blooms upon upright stems. Unfortunately, the catalogue states whether a Rose has this characteristic or not, so I will name a few of the best (white Moss),

Chloire Lyonnaise, Bonquet d'Or, Ulrich Benner, Gabrielle Luizet, Mrs. John Laing, General Jacqueminot, Abel Carrière, Climbing Perle des Jardins, Chloire de Dijon, Henriette le Beauveau, Charles Lefebvre, and Dupuy Jannin.—P. U.

I have just completed the planting of a sunny bank with Roses similar to what yours appears to be. In this case, however, the soil is extra good and deep, and the situation sheltered from rough wind, so that I had no difficulty in making a selection of choice Roses. The sorts included Chloire de Dijon, Réve d'Or, Madame Bérani, Safrano, Marie Van Houtte, W. A. Richardson, Climbing Victor Verrier, and Madame Gabrielle Luizet. If in your case the position is an exposed one you had better select one or two of the China Roses. Cramoisie-Supérieure would make a brilliant show both in early summer and autumn. Others of a more hardy and rambling character will be found in Danilee Rambler, Félicité Perpétuelle, Ruga, and Williams' Ecergreec.—J. C. C.

4906.—Roses and their treatment.—I am always glad to help any amateur to the best of my power, and it is gratifying to receive your thanks. L'Idéal is much more of a perpetual flowerer than the majority of strong climbers, and I think if you remove the weakest wood only, you will secure a ground crop upon the remainder by March. Bring them under cover at once now, and prune all of them in the usual way. If kept cool for a few weeks, and then introduced into the temperature you name—say about Christmas, or a trifle earlier—they will bloom in March.—P. U.

You appear to have treated your Rose L'Idéal in a very practical manner so far. With regard to pruning the two long shoots to which you refer, if you have room for them trained under the glass in your greenhouse they may remain their whole length, or at most only the soft top removed. If there are any short shoots in any part of the long ones, they should be cut back at once to the second bud from the base. In the matter of pruning those you have in pots, they should be dealt with at once if they require it, but the harrier you cut them back the bigger it will take them to start into growth. In my own practice I prune Tea Roses in pots for early forcing in June or July, if there are any unruly branches, and in November I merely take off the soft tops of any shoots that do not appear to be well ripened, but if the plants are dealt with in the summer for the purpose of pruning them into shape, they do not require but very little done to them in the winter. If you can only command a temperature of 50 degs. you had better not introduce them into the greenhouse until the beginning of January, and then it will be the end of March or middle of April before they flower. I may mention that I like to repot the plants within a week or ten after they are pruned if they require it.—J. C. C.

GARDEN WORK.*

Conservatory.

If Chrysanthemum blooms are to be kept as long as possible the house must be freely ventilated on fine, mild days, with a little air left on all night when not raining or freezing; and these must always be just a little warmer in the pipes to keep up damp and render the atmosphere fresh and buoyant. These conditions will also suit all other flowering plants. The least damp, for instance, will spoil Zonal Pelargonium and Bourdardias. Tree-Cactuses must have a light position near the glass; they associate well with Zonal Pelargonium. Plumbago repens, having now pretty well finished blooming, should be pruned back and receive less water at the roots; this plant blooms freely in small pots, and cuttings strike freely in heat in spring. Keep Freesias on shelves in a light position; give a little weak liquid-manure to the earliest plants, which are approaching the flowering-stage. It is time the Lily of the Valley, Spiræas, Solomon's Seal, and other forcing plants were potted now and plunged somewhere in a cool-house. Put Tuberoses in single pots as soon as they arrive; they will flower well if started in a greenhouse. Water once to settle the soil, and then keep on the side of dryness till there are signs of growth. I can sometimes tell to keep these things dry till they begin to grow; but there cannot be any growth without some moisture. Tea Roses which have been pruned, top-dressed, and rested a bit may be placed in a temperature of 50 degs. to get a start. The best possible place for starting Roses is a low, span-roofed house or pit, the pots plunged in a bed of loam where there is a little transpiration—just enough to cause a mild heat. This will set the roots in motion and the buds will break strong, and the growth will come as clean and healthy. Should insects appear

spring with a decoction of Quassia-chips, mixed with a little soft-soap; but there are plenty of liquid insecticides to select from that will kill insects without discolouring the foliage. Lately I have been using Sunlight soap, about 3 ounces to the gallon, for dipping and scrubbing purposes, and find it both effective and cheap. Fickler's White and other early-flowering Azaleas may have a little warmth now to start the blossoms. If there are signs of thrips on the leaves either dip or syringe.

Unheated Greenhouse.

Frost, if severe, will spoil the blooms of the Chrysanthemums, but a canvas blind which can be rolled down at night will be a great protection; the upright sides (at least the glazed portion) may be matted up as long as the frost continues. Use as little water in the house as possible, and ventilate early of every favourable opportunity; remove all dead or discoloured leaves, as they tend to encourage damp, and damp is quite as destructive to flowers as frost. Foliage will be prominent in this house. Several of the Fan Palms, such as Chamaerops excelsa, are hardy enough to keep in health sheltered by a glass roof, especially if canvas covering is placed over the roof on frosty nights, and such plants will take no harm if the covering is not removed for a week or even longer. Good Italianum, and other floridata, Jasminum multiflorum are valuable now, and good-sized pans filled with Stranbergia lutea are very effective. Clumps of Heliconia niger and its varieties are among the most charming plants for a cool-house. I have recently seen large clumps of H. niger maximum growing in tubs giving promise of producing hundreds of blossoms by-and-by. These give little or no trouble, and in summer hang about outside. Well-grown bushes of the variegated Eranthis have a fresh, brassy appearance, and some of the hardy variegated Grasses may be used for edgings to the border.

Stove.

The store Aralias may be grafted on seedling plants of Aralia Sieboldi. The grafting is a simple process; a slice is cut off the stem of the plant near the bottom, leaving a tongue at the bottom of the cut; a corresponding slice is cut off the side of the scion or graft, and the two are then fitted together and tied firmly with soft matting. The plants are afterwards kept in white cloths in a propagating-case for a time till the union is completed; the head of the stock is then removed, and the graft becomes the main plant. Very handsome are the tropical varieties of Apparagus, and so useful for many decorative purposes. To obtain seeds, set out a plant or two in a border and train under the roof of a cool store or intermediate-house. I saw a small house planted with A. plumbeus a short time ago; the roof was completely hidden, and there was a growth of stuff on each side of the plant. It is not easy to plant to propagate from cuttings; but with good seeds a stock may soon be obtained.

Cucumber-hous.

Do not encumber this house with plants in pots if it can be avoided. It may be used to bring on bulbs and to grow on young stuff in much smaller quantities than in a greenhouse in a very serious matter if green-fly or thrip were introduced. Winter Cucumbers are not difficult to manage. A steady night temperature of 45 degs., with a comfortable bottom-heat of 25 degs., will give all the heat required. Humidity in the atmosphere is necessary, but not to the same extent as in spring or summer. Pinching the growing shoots one day beyond each trill is a cardinal point in Cucumbers, and must be done in winter, and the pinching should be done when merely nibbling out or pinching the terminal bud will suffice. It is also important that frequent top-dressings be added to the borders; half an inch at a time will suffice. This top-dressing not only encourages the roots, but its tendency is to prevent stagnation in the atmosphere.

Cold Frames.

Where properly prepared Violas will now be flowering freely, Marie Louise being one of the best. Remove everything in the nature of decay from the frame, and ventilate very freely, even going to the extent of drawing off the lights when it is fine and mild.

Window Gardening.

Bulbs that were potted or placed in glasses each may now be taken from the black cellar or cupboards, but should not be placed in the full light all at once; this should be a gradual process, lasting a week or so. Primulas are fairly hardy, but must not be exposed to frost. When frost is expected take all the plants from the window to the centre of the room and cover with the newspapers.

Outdoor Garden.

The frost has come at last, and destroyed the brightness of the outside garden. A few things are still fresh and beautiful, notably the pretty yellow autumn-flowering Anagallis, or Sternbergia lutea. The Christmas Roses are on the move, and where as largely grown as they ought to be a good deal of interest will be inspired as the blossoms unfold. An amateur friend who has rowed off clumps in his garden covers them as soon as the flowers show some faint hints of light. In cold tenders I advise the Christmas-Roses seem to have suffered from the drought of the past summer, especially where exposed to bright sunshine. A heavy mulch of leaf-mould is good for Christmas Roses, and such things as Hepaticas and Hardy Cyclamen. If any bulbs remain out of the ground get them in at once. Groups of Chionodoxa Lucida near the front of the border will be charming next spring, and the bulbs are cheap now. Every year there is a greater demand for effective hardy plants that will do for a couple of flowers; and even now are the Perennial Guillardias, of which a grand variety may be taken as the type. Another plant that everybody should secure for next year's cuttings is the White Everlasting Pea. I have seen it trained over a wire arch and up the stems of Apple and Laburnum-trees, and in all positions it was effective; it should have plenty of nourishment. It is always possible, by a rearrangement of the furniture of the room, to make the room more interesting. The same thing occurs in the garden. Put down some of the cutting of Coccinea Lilies and Luteals, and introduced things of better character.

Fruit Garden.

The open weather continues push for and the plants and pruning of fruit-trees. No one should neglect young trees. The reason why so many old fruit-trees are

tolerated is, it would take so long to get up a young tree to fill up the blank; but a few coning trees, selected so as to keep the collection of fruits well up to date, were planted every November, there would always be trees of a bearing size to fill up blanks; and the lifting of coning trees has always a beneficial tendency as regards fertility. As regards Pears, it is generally admitted that Marie Louise and Docteur du Conice stand in the front rank. They bear good fruit, and have constitutional vigour, and are both so ready to make headway under the changed conditions of soil and climate to which we are exposed. These two kinds had made a reputation, and in the long list of varieties catalogued there are plenty of good Pears that will some time in the future, when better known, be largely grown. There is, I am convinced, a future for Pear-growers where the soil and climate are suitable. I was in a garden a short time ago where long lines of cordon Pears stretched across the garden, six feet high, and laden with fruit of the best kind. The stocks had been planted in rows, and the Pears lashed upon them, and nothing could have been simpler, cheaper, or, I might add, better. Stocks are cheap enough, and on heavy soils, if the Quince is planted but close to the ground, in a short time the trees will be on their own roots. The same course may be practised with the Pear-stock, and as the trees shoot up strain some wires along, and in a few years there will be bearing trees.

Vegetable Garden.

The autumn has to a large extent made amends for the summer, and vegetables of all the usual kinds are very plentiful. Cauliflowers are splendid. Brussels Sprouts, where planted early enough, are a good thing, and sown with button-like sprouts, as tender as marrow, become quickly grown. Peas, at the time of writing, in some gardens are coming both green peas and blossom, and turnips and all kinds of roots sown for use in winter have done well. After the rains came copiously vegetables came on by leaps and bounds, and the gardens now overflow with vegetables. The earth, when well cultivated and cared for, will always respond generously to the efforts of the cultivator. Gather up all the tree-leaves every where, and store them for making hot-beds. A heap of fermenting leaves, placed round Rhubarb or Seakale stools, will speedily start it into growth, and hot-beds will be ready to be sown for Potatoes, Carrots, Apparagus, and other things. Scarcely anything in the solid way equals a steadily-grown lettuce from a gentle hot-bed. French Beans must have genial warmth; 60 degs. to 63 degs. at night is not too warm. Stake the Beans before the plants fall over, and when maintained in an erect position they grow better. Vetch's Autumn Self-protecting Urve oil should be in every garden. The leaves fall closely over the heart, and with frost a deal of protection, and even frost will, of course, spoil the hearts, but up to the present they are all right, but before frost comes very sharp have them laid in a trench, where a ruler of dry Fern or some such can be laid over them. Cucumbers will have water at the roots when hot pipes are used for bottom.

E. HONNAY.

Work in the Town Garden.

Two or three sharp frosts have at last cut off the Dahlias, Begonias, and other tender plants, except in exceptionally sheltered places, which have until recently been so gay. The roots or tubers of all such tender subjects should now be lifted out stored before they can be injured by frost of sufficient severity to penetrate the ground. The best way to treat Dahlias roots is to lift and treat them most of the earth, cutting down the tops to 2 inches or 3 inches of stem, to which the labels should be secured with wire; then lay them out in a shed or loft for a week or two to dry, and finally store them away for the winter in a cellar under the stage of a cool greenhouse, or in any other place from which frost is excluded, and which is neither very damp nor excessively dry. Both these extremes are injurious to Dahlias roots, as well as to those of the Tuberoses Begonias, which, in the whole, should be treated in the same manner; but in this case let them become tolerably dry before cleaning off the loose earth, especially if this is of a calcareous description, or the skin is liable to come away too, and this should be avoided. Gladioli should be taken up, cleaned, dried to a moderate extent, and then stored for the winter in paper bags or on shelves in a dry room. Roots of Salvia patens, the Marvel of Peru, and the tall or hedgeous Lobelia keep best with a moderate amount of half-moist earth round them, and those of the handsome Tigridias must never be allowed to become quite dry, or, though they may survive and grow, they will not flower the following season. It is high time now for Hyacinths and others to be grown in pots or glasses to be got to work, and, indeed, this would have been better done a month ago, at any rate for early or moderately early blooming. Put a bit of charcoal in each glass for Hyacinths, which will greatly aid in keeping it sweet, and place the glasses in a cool dark place—not in a warm one, or the tops will start before the roots and the flowers come to nothing. A pretty and easy way of growing these, Philips, Norvich, and other tuberos subjects for window or room decoration is in damp or rather wet sand or Moss; this is chosen that soil and just as effective, and the bulbs may be accommodated in any number in pots, pans, bowls, boxes, or the like. As soon as Gloxinias die down the tubers should be shaken out of the soil, rained, and then stored, with some half-moist, fresh Cocoa-nut-fibre among or round them, in large pots or bowls, placing these where a temperature of not less than 45 degs. to 50 degs. is maintained, and avoiding extremes of both wet and dryness. Chrysanthemums under glass are now in full beauty; prolong the life of the flowers by means of a cool yet genial, buoyant, airy, and moderately dry atmosphere. Begin inserting cuttings of naturally early varieties towards the end of the month.

B. C. R.

THE COMING WEEK'S WORK.

Extract from a garden diary from November 18th to November 25th.

On 18th I planted in the Valley for forcing, also Spiræas and S. japonica's. The last in good-sized clumps, in very large pots, either for planting in the conservatory, or for some good-sized clumps of Christmas Ros, in addition

* The old or winter's districts the ground is not yet frozen. Garded Woodstock is the best of the late season, and a fortnight later than the other districts. The ground is not yet frozen.

variety. They were fitted with as little disturbance of the roots as possible, and placed in large pots, and will be brought gently, without much heat, as the blooms will not be required before Christmas. Dipped Cinerarias and Boniards of a high a few files had assembled in a solution of sunlight soap, two ounces to the gallon, one ounce of T. d'arces powder being added to three gallons of the solution. I had this quite effectual in destroying green-flies on plants generally, and is much cheaper than imitating when only a few plants are attacked. Finished pruning Gooseberries and Currants, and dusted them with soot and lime. I should dress them with the soot and lime even if I had no fear of birds, as it brightens and cleanses the bark, and when the bark is freed from parasites the trees are healthier. Planted more calabages and Lettucers. Planted a few roots of Chicory and placed in Mushroom-house. Made up another Mushroom-bed. I never allow a bed-space to remain long empty at this season. Took up Senkale for forcing. This is generally taken in quantity now, and laid in thickly on the north side of a wall, where it will be ready for moving to the forcing-bed as required. Will be covered with litter if frost sets in. Placed some old manure round the stems of Globe Artichokes; shall cover with litter when frost comes, just a forkful over each stool. The mould round the stools would probably be a sufficient protection most winters, but when badly frozen they are so late in starting, hence the value of a forkful of litter. Unnailed Fig-trees from walls, and tied the branches close together, to be ready for covering up when frost sets in. I do not believe in covering hill hills is necessary, but five minutes' work and a few mats will save the crops if the winter should be severe. Put out of Tomato seedlings. These will be sown on gently near the glass. A lot of robust plants are required for planting a house first week in January. Ham Green Favourite is the chief variety I have grown, also Criterion, Conference, and the old Bird. The last named is a good seller and cropper, but its shape is not liked, and Conference and Criterion are rather too small. I think bad setting is frequently due to errors of management. Too much or too little water, deficient ventilation, or mild draughts will cause the flowers to drop instead of setting. Tomato-houses should never be altogether closed, except in very cold or windy weather; and the same thing may be said of all plant-houses, except the stove and the forcing-houses. The houses where Chrysanthemums are staged are left open at night, and the flowers in consequence keep much longer.

4794.—*Erythrina Crista-galli*.—This is a very old garden plant, and I have in a quill "T. A. F." can obtain it from my nurseryman who deals in greenhouse plants. It is a native of Brazil, and was introduced into this country about 120 years ago. It is often called the Coral-tree. In the South of England it is almost, or quite, hardy, forming at the ground a stout root-stock, from which the shoots start each spring, dying back again in autumn, as it is biheraceous in character. The finest plant that I know is in a southern garden. It is in a border at the end of a glass-house, and has been there close upon thirty years. It never fails to flower freely, and this year has been magnificent, owing to the excessive heat. The only winter protection it gets is covering the crown with ashes. It can be used with good effect in the summer flower garden, and when employed in this way the plants are lifted and stored away from frost in a cool-house. If "T. A. F." has the convenience he may raise his own plants, as seed is procurable from some of the leading seedsmen; but it must be sown in heat. The plants will not grow very large, however, the first year. Although old, it is not common, and its effect in flower is so striking that I had many inquiries concerning it a few years ago when I used it among the summer bedding plants. It was formerly well grown at Battersea Park, and perhaps is still.—A. H.

4804.—*Double and Single Violets*.—There is no better plan than picking off the affected leaves as they begin to turn yellow. You may, however, try syringing them with soapy water in the morning when it promises to be a dry day, but Violets are so susceptible of damp in the winter months that syringing is a doubtful remedy. You cannot do better than remove the affected leaves. You had better try and get a clean stock next year by allowing the runners to remain upon the plants from this time, and early in the spring peg the runners down on small pieces of turf about 2 inches square, or else on the bed of soil. By the time it is safe to plant them in the open runners will be well rooted. Meanwhile choose a shady border if you can for the plants to occupy next summer, and place a thin layer of manure about 3 inches under the surface. The roots will soon find their way down into it, and the growth under such conditions will be so vigorous that it will in great measure be able to repel the attacks of red spider. If your plants occupy a pit or frame that is heated by hot-water pipes, a little warmth from the pipes in cold, foggy weather will do good, but an ordinary hot-bed is not at all suitable unless you have a number of plants in pots. In that case you may make up a bed with tree-leaves 3 feet

high, and after placing a frame upon it, plunge the pots to their rims in the leaves, and within 6 inches of the glass. The warmth from the leaves will be just enough to keep the plants steadily growing in fairly good weather.—J. C. C.

HOGARTH HOUSE, CHISWICK.

WILLIAM HOGARTH'S house is one of the many good examples of domestic architecture scattered over the home counties, particularly in South Middlesex, through the old suburbs of Fulham, Hammersmith, Chiswick, Brentford, and Isleworth. They date from the end of the 17th Century. Some say that Hogarth never owned the house, but the Prebendal Court Rolls show that he acquired the copyhold on September 13, 1749, while he was living in Leicester-square or Fields. It was then that the Earl of Burlington built old Chiswick House. Hogarth House was also planted in the fields about a quarter of a mile northward, and midway stood Turrel House, long since pulled down. In Burlington House stood The Cedars, Fairfax House, and Boston House, and between these and the Thomes, Corney House, now pulled down, and which gave its name to that part of the river. Like nearly all that class of house, 9-foot high walls were built round the grounds, which were

ture of about 80 flegs. A little basket of hay in the kitchen is a good place for a tortoise in winter, when they are mostly asleep; but when they wake up they should be supplied at once with food and a little warm milk. Clean, fresh water, too, should always be within their reach. They live for years under kind care, and sometimes lay eggs during the summer.—L. L. R.

WHITE FLOWERS FOR AUTUMN.

IS gardens of any extent the demand for white flowers is an all-the-year-round one, and unless care and forethought are exercised in growing hardy plants, that flower late in the season, there is a great deal more required from the tender plants under glass, and at this period of the year there is not so great a variety of plants to select from. I find the following hardy plants give us great help in maintaining the supply up till the time that severe frosts cut off all exposed blossoms:

ANEMONE JAPONICA HUNGARICA JOBERT is of the easiest culture, and flowers for a long period, as it continues to throw up flower-spikes from the base until stopped by frost, and as the individual flowers have footstalks long enough to allow of their being used for many decorative purposes there is no need to cut the whole stalk at once.

CHRYSANTHEMUMS of the early-flowering section are invaluable aids to the autumn flower basket. Mme. Desgrange and the beautiful Lady Fitzwygram begin to flower in July, and continue to do so until October, for if old plants that have been kept in pots or boxes in cool frames during the winter are planted out in April, and not pinched in at all, they will come very early into flower, while those grown from cuttings and pinched back once will not come into flower until September, and will continue the supply until many of the second early whites are in bloom. As an instance of the effect of hastening or retarding varieties, I may mention Mme. Lacroix as one of the finest whites at our early autumn show, yet it is one of the best for very late blooms.

CHRYSANTHEMUM MAXIMUM, one of the largest of pure-white

Daisy-like flowers, although one of the best of white flowers at midsummer, keeps on flowering right up to November if mild weather prevails; and it is well worth giving the plant a partial cutting down in August when there are plenty of other white flowers, and encouraging these to make a late growth.

DALIAS are not very reliable, owing to their liability to get cut off by early autumn frosts; but on the sea-coast they flower even better in October than during such scorching summers as we have just passed through, when Dahlias did not at all come up to their usual excellence; but up to quite lately the White Cactus and Pompono varieties have been very beautiful.

MARGERITES (white) are nearly all the year-round flowers, and planted out in good soil they continue to grow and flower as long as any bloom can reasonably be expected. I am still cutting from plants that have bloomed for months past, and they still appear full of buds.

PYRETHRUM VILGINOSUM is one of the finest of all hardy autumn flowers, sending up spikes of bloom 6 feet high, crowned with heads of large white flowers. It is specially effective in autumn floral decoration. It requires deep, rich soil, plenty of manure, and transplanted every year. It is not nearly so much grown as it merits as a cut flower until it to

Hogarth House, Chiswick. Engraved from a photograph sent by Mr. Alfred Dawson.

and still are very tasteful and dignified old gardens. In these places fine trees were much patronised, Cedars of Lebanon and Mulberry-trees being favourites, and the fine effect of these old specimens is well seen at the present time. The well-known Mulberry-tree here shown from which William Hogarth doubtless often plucked fruit is one of them, and with the necessary bit of lawn underneath it forms the best possible set-off for such a house. The place has been recently acquired by Mr. Alfred Dawson, who has carefully restored it and repaired the injuries done to it during the last twenty years of neglect.

4820.—*Tortoise in a garden*.—There are two distinct kinds of tortoise, which are both sold in large numbers in the streets of London. The web-footed kind, or water-tortoise, eats worms, fish, and a little raw meat, and this should be supplied to them when they need it in winter. The land-tortoise, whose feet are not webbed (and the shell is higher and more steep), eats green food, such as Lettuce, Dandelion, Cabbage leaves, Grass, and Clover, which he cannot supply for himself in winter. Either kind needs a warm place in winter, though they have been known to do well in an unheated greenhouse, certainly they will die if exposed to the garden in winter. They should have a tempera-

be. On good soil it continues to branch out and produce its feathery white flowers for months, but it needs a late sowing to produce plants to flower in September and October.

J. GIBSON, *Co. port.*

OUTDOOR PLANTS.

PERENNIAL CANDYTUFTS (IBERIS).

In reply to several inquiries, evergreen plants, such as the Iberises, Dwarf Vaccinums, and the like are indispensable to a rockery. They should be planted as much with an eye to effect in the dead of winter as when they are in full flower

A Perennial Candytuft (*Iberis gibraltarica*).

in spring. The hardy species are all evergreen, and as they mostly form dense, healthy green cushions, these take the bareness of the rockery in the dull months as well as contribute to its beauty in spring and early summer. They are, however, most effective where they can hang over ledges, such as down the face of old walls, rocky banks, &c., and here, too, the more tender sorts would be much safer than if planted in the ordinary way or in the border. As spring bedding plants they are extremely useful, and they may be increased from cuttings in any quantity.

Iberis nummularia. This (here figured) is a native of Gibraltar, and was introduced into this country about 1732. It is one of the most popular of the genus, and with its variety *hybrida* is in great demand for winter flowering. It grows about a foot or so high, closely branched and tufted, with leaves and flowers much larger and more ornamental than those of any other species. It is, unfortunately, not perfectly hardy, unless the plants when young are established in an old brick or stone wall, and even here they are apt to suffer, especially in wet seasons. It may, however, be easily kept in a cold frame or greenhouse, where it will continue in flower throughout the winter. As greenhouse subjects both the species and variety are invaluable, their compact habit, fresh green leaves, and abundance of lilac and creamy-white flower-heads come at a time when most required; indeed, they may be utilised at almost any time, as they are rarely out of bloom. Plants well hardened might be tried in warm nooks of the rockery, and with a small piece of glass to ward off excessive moisture they might do well. It is a good greenhouse or summer plant, however, that this species proves most useful, and as it is increased from cuttings or layers with the greatest facility, no fear of losing it need arise. The variety is more compact in habit than the type, with large bunches of creamy-white or rosy-purple flowers.

I. Purrrr is a native of Sicily, and one of the most beautiful and useful of the hardy kinds for the rockery or border. It is little inferior indeed to *I. gibraltarica*, with the advantage of standing our severest winter. The flowers, of a pure ivory-white, are produced in abundance in compact corymbs, and continue from early May until July. The stems are shrubby, of the size much branched, and rarely exceeding 9 inches

in height. It is nearest to *I. Tenoreana*, but the leaves are smooth, not ciliated, and the flowers pure-white, not purplish, as in that species. It is a really useful species for the rockery, where it should be planted in gritty soil and facing east.

I. SAXATILIS, widely distributed in Southern Europe, is the dwarfest of all the species in cultivation. The stems are procumbent or trailing, not ascending, as stated in many books. It forms dense tufts of very dark-green, narrow leaves, quite entire, with somewhat ciliated margins. It is very free blooming, producing small bunches of pure-white flowers from early April until June. It was introduced about 1740.

I. S. VAR. CORREIFOLIA is supposed to be a hybrid between *I. saxatilis* and *semperflorens* or *Garreixiana*. It is a very neat, shrubby plant, taller and not so densely matted as the above, and producing its flat heads of white flowers from May to June. It is very easily propagated from cuttings or layers, and is often used as an edging for walks, &c. It is very neat and effective when in flower.

I. SEMPERFLORENS is an autumn and winter-flowering species, and unless in southern counties is not of much use as a hardy plant. The flower-heads are large, the flowers pure-white and sweetly scented; the leaves quite entire, smooth, and dark-green. It is a native of Sicily and Italy. *I. humilis* is a synonym.

I. SEMPERFLORENS.—This fine species is the common perennial Candytuft of our gardens, and with its variety *Garreixiana* is the species commonly met with in small places. It is quite as popular as the yellow Alyssum, and deservedly so, as it requires little attention and is attractive in winter as well as summer. It is evergreen, half shrubby, spreading, and will be found useful for old walls and such-like places where plants can get a foothold. It grows about a foot high, and seems to flower more freely in a gritty soil than in any other. There are several garden forms, the best of which is *asperula*, a really charming variety, free and effective. Greece, &c.

I. S. GIBREXIANA is a much dwarfier plant than the above, with smaller heads of white flowers, and a very useful rock plant. It flowers from April to June, and is a native of the Tyrenes, &c.

I. TENOREANA.—A common species in Italy, Spain, and Portugal, and known in some gardens under the name of *I. petrea*. It differs from all the other species excepting *gibraltarica* in the colour of its flowers, which it produces in profusion throughout the summer months. Like *I. gibraltarica*, it is not to be depended upon as a perfectly hardy plant, and when left out some little protection should be given to it. In a well-sheltered nook and in free well-drained soil it does well in the south, where its mass of purple flowers is always welcome, but in any case it can be easily treated as a biennial or even as an annual by striking cuttings in late summer and planting out in spring. It is well worth the trouble and is really effective when well grown. D.

4892.—**Treatment of Dianthus.**—They are all forms of *Dianthus sinensis*, and form a very charming group of flowers. I saw a bed of them in the Zoological Gardens this year which was quite a picture of colour, varying from white to crimson, through many intermediate shades. One can get a host of named kinds, and also mixed. The *Bride* is snowy white, with dark centre, and *Purple King* deep-crimson; but you may obtain a good selection of your own by saving seed of the best forms. The seed should be sown early in the year in pots under glass and placed in moderate heat. Pot on, and gradually harden them off to put out in May. They soon begin to bloom, and maintain a succession through the summer. Another way is to sow out-of-doors in August, and the plants will be stronger and more compact than those raised later.—C. T.

4900.—**Ribbon border.**—I had hoped that the taste for ribbon borders had quite died out. I have grown and turned out thousands of plants into ribbon borders, but though bright enough in its way it did not yield satisfaction for the enormous amount of labour required. The following plants will afford contrast—Back row *White Dahlia*, *White Bedder*. Second row *Saxa patens* and *Calceolaria amplexicaulis*

mixed. Third row: *Scarlet "Geranium" Master Vesuvius*. Fourth row: *Pink "Geranium" Mrs. Miles*. Fifth row: *Variiegated "Geranium" Flower of Spring*. Sixth row: *Iresine brilliantissima*. Seventh row: *Golden Feather* or *Crystal Palace Gem "Geraniums"*. Eighth row: *Lobelia Crystal Palace compacta*. A border 7 ft wide will require right rows of plants.—E. H.

Your border is too wide for a ribbon border, which signifies rather a narrow strip wherein Alternantheras, bedding Lobelias, and similar things are arranged. Of course, you can fill it with Pelargoniums and the usual run of bedders, but nothing in this way will succeed under the shade of trees. Such a border affords splendid scope for getting together a really first-rate display of hardy flowers, such as Achilleas, Adonis vernalis (spring-flowering), Alstromeria aurea (summer), a free-blooming plant, Anemone japonica alba (autumn), Hepaticas (spring), Michaelmas Daisies in variety (autumn), Campanula persicifolia (summer), Coreopsis lanceolata (the same season of flowering), also Delphiniums, the Fraxinella, Erigeron speciosum, Sea Hollies for the drier, summer spots, Galega officinalis alba (the White Goat's Rue), Irises in rich variety, Gypsophila paniculata, Day Lilies, White Lujine, Lychnis Haageana (flowers of various colours), Lythrum salicaria roseum, Oriental Poppies (splendid in bold masses), (Anothera frutescens, Rulbeckia speciosa, Sedum spectabile (autumn), and a host of beautiful bulbs for spring—Anemaris, Daffodils, Tulips, Lilies (summer), Squills, Hyacinthus candidans (August), Crocuses, and Fritillarias. I hope you won't make a blushing-rod affair of it. In the shadier spots you can get Solomon's Seal in perfection.—C. T.

THE HEMP-PLANT (CANNABIS SATIVA).

The Hemp-plant, a tall and graceful member of the Nettle family, is generally believed to be a native of Asia, although cultivated for centuries nearly all over Europe and also in Africa. It is in northern climes that its fibrous qualities or bast tissues are best developed; but

Hemp (*Cannabis sativa*).

in India it is largely grown for its resinous narcotic products, such as Gunjah, Bhang, or Hashish. The Hemp-plant is diocious, a fact long known to agriculturists who have grown it as a fibre-yielding crop. Thus Threlkeld in 1727 especially tells us that the more attentive husbandmen observe that, in a fat soil you have more male plants of Hemp, and in a lean soil

more of the male. The use of Hemp-seed in the fattening of poultry is not so well known as it deserves. It is a matter of history that Queen Elizabeth used a milk-like emulsion of Hemp-seed, and so escaped the markings of small-pox, and the oil of the seed is a specific for burns. In the garden, however, we are mainly concerned with Hemp as an ornamental plant, of which there is a giant form, but even the ordinary attains a height of from 5 feet to 10 feet in good rich soil. As shown in the illustration on p. 514, it is a plant of elegant habit, and a good group of it serves admirably as a background for more showy flowers, while its light feathery growth contrasts well with Castor-oil plants, or with the stiff-leaved Yuccas and Dragon-trees, Aralias, or Ficus during the summer months as used in the open air. Hemp is a robust annual plant, very easily raised from seed. Sown in a gentle bottom-heat, strong young plants may be had for planting out about the middle of May, and as the plant grows very rapidly, it is peculiarly effective and distinct from most other annuals commonly met with in the open-air garden. The engraving also well illustrates the grace and beauty of a good-habitual plant as well placed near a suitable background of shrubs, instead of being mixed with other things. B.

4884. — *Ostrowskya magnifica*. — Almost any soil and situation will suit this great Oriental Bell-flower, but it prefers a deep sandy loam. It is a striking plant, and must have good culture to bring it to full perfection. Its long fleshy tuberous roots descend into the ground for quite 2 feet in depth, and this fact indicates the necessity of having a soil that has been deeply worked for growing this plant. The soil should, therefore be broken up to quite this depth, and if it needs manure, some that is well decayed may be incorporated. Its long fleshy roots are very much like those of that charming though little-grown biennial *Mischocixia campanuloides*. When planting, the roots need to be carefully handled, as they are decidedly brittle and easily broken. They may then be left alone, as though commencing to grow early in spring, the plant is absolutely hardy and does not need the slightest protection. It is a comparatively new plant, but is now easily obtainable, as it seeds freely. Seeds can be bought, but those who raise their own plants will have to wait two or three years before they are rewarded with flowers. — A. H.

— I don't think this at one time promising plant is of great garden value. Its flowers when in full beauty are very handsome, but they are never to be depended upon. The best species I have seen were those that were shown a few years ago, but since then I have never seen it well grown. It appears to be like the New Zealand Forget-me-not (*Myosotidium mobile*), described in GARDENING a few weeks ago — pleasing enough to look at, but terribly hard to grow. — C. T.

4881. — *Plantains, &c., on a lawn*. — There is no better way than digging them out. It is a tiresome business, but if a good boy can be captured a moderate-sized lawn need not cost much. In very bad cases it may be as cheap to cut up the turf, dig over the ground and pick out the roots of the weeds, and then weed the turf and lay it down. Roots of Dandelions are difficult to get up, as they descend so deep in the earth. Lawns are more ready than usual this autumn, especially where much burnt up in summer. The Grass itself and the weeds took possession. — L. H.

4878. — *Outdoor plants*. — All spring and summer-flowering subjects of a thoroughly hardy nature ought to — and, indeed, must be — planted in the autumn if they are to flower to any extent next season. Those of a comparatively tender or delicate nature, such as *Peutatomus*, *Lil-astrum*, and others had, however, better be left until March or April, especially where the soil is of a heavy or damp description. *Chrysan-themums*, *Mischocixias*, *Daisies*, *Tulipums*, *Philoxas*, and other late-flowering plants are also best removed in the spring, just as the fresh growth is commencing. But, as a general rule, autumn planting is decidedly preferable for the majority of this class, particularly where the soil is fairly light and well-drained. — B. C. R.

FERNS.

SMALL BASKET FERNS.

I AM asked by "C. P." and others to name about a dozen small Basket Ferns that will succeed and make handsome specimens in a stove, together with some hints as to their management. The baskets must be well finished, and the soil in them must be solid and firm. The plants must never be allowed to become dry at the roots, the

A good Basket Fern (*Asplenium filifolium*).

heat must never fall below 60 degs., and there should always be a slight moisture arising from below. This will allow of a neat growth and prevent the pinnae of the older fronds from becoming browned and disfigured. The baskets may be of galvanized wire, and the soil should be composed of good light turfy loam and fibrous peat in about equal parts, the whole made sandy. The drainage I should advise to consist of charcoal, because of its lightness. This should be covered with a layer of Sphagnum Moss. The varieties I should recommend are as follows: —

GYMNOGRAMMA GLORIOSA is very handsome when grown as a pot specimen, but when seen as a basket-plant it is far better. The fronds, which are very finely cut, are of a light-green, sowing a little white farinose powder at the base of the stem.

ADIANTUM DOLABRIFORME. — A plant with thin dark-brown or black stems, which throw out young plants from the ends of the fronds. The pinnae are entire and somewhat in the form of *A. lunulatum*. This plant is superior to *lunulatum*, inasmuch as its fronds remain green throughout the year.

LUZIOLEPIS FILOSELLAIDES. — This makes two kinds of fronds; both are entire, the fertile ones being linear, pale-green on the upper side, below furnished with large reddish-brown sori; the sterile ones much broader, but, like them, pale-soft-green in colour.

DRYINARIA MUSEIFOLIA. — This is a somewhat larger grower than the other kinds, with entire fronds, which are so exquisitely beautiful in their venation, that it must perforce find a place. The fronds are pale-green with dark-green veins.

ASPLENIUM FLABELLIFORME (see cut). — Although this plant is a native of Australia, it will be found to grow well in the stove. It has neat little flabellate fronds, which are dark-green and the streaks of sori on the under side render it very handsome.

NEPHROLEPS TRICHOMANOIDES. — This plant makes pendent fronds which are each from 1 foot to 18 inches long. The pinnae are very deep-green on the upper side, below covered with white scales, and have a continuous row of jet-black sori round the margin.

PLEKOPETIS STIGMATICA depends for its beauty upon its exquisite venation, which is much added to when fertile.

DAVALIA PYRMAI. — A charming plant, making stout rhizomes densely clothed with large silvery scales and deep-green fronds, which are very thick and fleshy.

GONIOPTERIS GRACILIS. — A Fern with pendent fronds some 18 inches long, the pinnae being of a rich deep-green.

DRYINARIANUM FILOSELLAIDES. — A singular little Fern from Japan and the East Indies, which is well adapted for this particular purpose. Its fronds are of two kinds, the fertile ones long and narrow.

HYPOLEPIS DISTANS. — The fronds of this are from 6 inches to 1 foot long. They are finely divided and deep-green in colour. J. J.

DIPLAZIUM.

This is a very beautiful family of Ferns, which a reader signing himself "C. Wickie" inquires about. I do not make any doubt but the various kinds of which he sends specimens are all of them species of *Diplazium*, but then they are so poor, and the fructification (when present) is so old and worn that it is quite a task to decipher them correctly, and I would fain take the second part of his letter in hand in the first place and tell him something of these Ferns, and name a few that are worthy of a place in every collection of stove Ferns. They for the most part are large branching plants similar to the *Aspleniums*; indeed, they differ but very slightly. They begin to fruit when quite young, and these fronds differ so widely from the fronds upon the same plant when mature that the names get quite confusing; then another cause is through their being large growing plants, and perhaps the fronds have only been dried in halves, so that their natural form is quite hidden. They are Ferns that thrive well if planted out in the stove fernery. They like an abundant supply of water during the summer months, therefore they require ample root drainage in order to carry it away quickly, and during the dull months of winter it must be given more judiciously. The following kinds will be found most distinct and attractive. More might be added, but these will be found quite enough for most purposes. *Diplazium arborescens*, *D. brevitorum*, *D. costale*, *D. celtidifolium*, *D. coarctatum*, *D. Francoeni*, *D. grandifolium*, *D. juglandifolium*, *D. lanecum*, *D. plantagineum*, *D. Thwaitesii*, *D. zeylanicum*. J. J.

Original from
4890. — *Ferns not thriving*. — The past summer has been very trying to Ferns, unless carefully and frequently watered, shaded, etc.,

CHRYSANTHEMUMS.

SEASONABLE NOTES.

PREPARING PLANTS FOR CUTTINGS. — No sooner have the blooms faded upon the plants than a start must be made for next year's display. The preparation of the plants for giving a supply of sturdy cuttings is an important detail in culture too often neglected by the amateur, I fear. If the cuttings are not sturdy and clean, I fail to see how a proper foundation is to be laid to ensure future success. Some varieties are notably shy in producing cuttings at all, and especially the right kind. Those most desirable push through the soil a few inches away from the stem, for the reason that the growth is not inclined to run prematurely to the production of flower buds, as in the case of those growths coming direct from the stem. Still, where the variety is scarce, it is better to have stem cuttings as none at all. The objection to stem cuttings is that they, as previously stated, are apt to form buds instead of growth. No difficulty would be experienced in striking these banded cuttings, but the chances are that before they had grown beyond an inch or two, other bloom buds would form instead of growth shoots. The proper way to manage the plants that have flowered that are known to be shy producers of cuttings, is to cut them down to within 2 feet of the soil. Those that throw up freely from the base, like the "Queen" family, for instance, should be cut down to within a few inches of the soil. Place the pots containing the old roots or stools in any end-hous, sash-frame, or at the foot of a south wall, providing the frost is kept from them. Ainery or Peach-house at rest affords a good situation where plenty of light is available consequent upon the leaves having fallen from the fruit-trees. Place them as near to the glass as possible to induce a stocky growth. Cold frames answer very well, but there is the trouble of covering them in the case of frost, the young

growths being tender at this stage, consequent of their having been gnawed a long way from the glass prior to cutting down. In the case of those varieties that have cuttings several inches long at cutting-down time, if these new growths are left by the time the cuttings are required, they will have become drawn up weakly and rendered useless as cuttings. It is better in such cases then to remove the tallest at once, allowing more space for those coming through the soil at the time. A better class of cutting is obtained when required by this means. In the case of reputed shy producers of cuttings means must be taken to induce them to grow more freely. Examine the drainage to make sure the plants are not waterlogged, and remove any manure from the surface used for top-dressing, if the roots have not run into it. Replace the manure with loam and leaf-mould in equal quantities, adding sand freely. Cover the roots with half an inch of this compost and avoid anything like keeping the roots wet. With the plant cut off and no growth at the base, but little water will be required. It is wise to keep such plants on the dry side at the root for a time until a better action is apparent. Syringing the stems during bright weather is a means of encouraging new growth. Those starting freely should have all the air available to ensure a robust growth. Those that are sluggish in this respect would be all the better for a gentle bottom-heat, if available, or be placed at the warmest end of the house. Greenfly occasionally attacks the joints of the young shoots, and should be got rid of quickly for fear of its crippling the young leaves, thus causing a check to the free growth. Where fumigating with Tobacco-smoke is not practicable the affected points should be dusted with Tobacco-powder, vigorously syringing the points the next day with clean water to remove the cuttings of both powder and fly.

E. MOYLENA.

4891.—**Chrysanthemum M. G. Grunerwald.**—There should be not the slightest difficulty in getting this variety. Any good Chrysanthemum nurseryman, such as Mr. Davis, of Lilford Road Nurseries, Camberwell, or Mr. Jones, of Hilder Green-lane, Lougham, will supply you. It is a closely early variety, probably a seedling from Mme. Desgrange, the

But very likely it will grow all the more strongly next season, especially if the plant can have a little extra warmth when starting into growth, with a nice moist atmosphere. Good fibrous loam, mixed with a third of leaf-mould, some sand, and a small quantity of "ballast," varying in size from a Pea to a Hazel-Nut, will grow these Ferns well. —B. C. R.

—Pterises are so easy to grow that I never care to keep old plants, as young specimens are more effective. In the present case, if it is intended to restore the old plant, keep it rather dry till February or March, then shake away most of the old soil, and divide the plant into two or three, and pot in rather small pots, shifting on as more space is required. All this family will grow well in loam and leaf-mould in equal parts, with some sharp sand to keep the soil from getting too close, the sand to be used liberally if the loam is heavy, and less if the loam is sandy. The loam found round London is the best for Ferns. —E. H.

—Evidently the plant requires repotting. It has thoroughly exhausted the soil, but wait until early March, when take the plant out, divide it, and use for a soil a mixture of loam and peat, with sufficient sharp silver-sand to keep the compost fairly open. Provide ample drainage, and place in moderate heat to encourage quick formation of roots. Water very carefully for a few weeks. If newly-potted things get too much they rarely succeed. —C. T.

ORCHIDS.

ODONTOGLOSSUM BLANDUM.

I AM in receipt of a spray of flowers for a name from the Leeds Orchid Company, which certainly does appear to be of this species; but it is too far gone for accurate recognition; consequently, I am compelled to simply guess at the name, which is a thing I do not like doing, because it may lead to error, but I do think this Orchid is *O. blandum*. This plant was first found by the collector for Messrs. Low and Co., now some thirty years ago, but the assignment went home to that firm were all dead, and so from time to time the plants sent over here by numerous collectors all arrived in a similar condition, and so this state of things continued; thousands upon thousands of these plants were sent home, but all arrived in a putrid condition. This caused a severe rebuke from Reichenbach and others, and, indeed, we were told that the Orchid was becoming extremely rare, and that it appeared to be soon becoming an extinct plant, and that fears were entertained that we should never see it in our collections in anything like the beauty exhibited in its native home. Now what was the cause of the sad destruction of the plant, and why did it come home in such a bad condition? Well, this was the fact—this *Odontoglossum* grows naturally in a very wet climate, and the collecting it in such great quantities, and packing them closely in boxes, only led to their decomposition on the journey home, and it was not until greater care was exercised in their transport that we began to see it at rare intervals in our collections. It remained scarce for some time, but now I see it is more plentiful, and I find it about in many collections where *Odontoglossums* are well done. It is a plant that was at first thought to require a very cool atmosphere; but I have found it to thrive well in the same temperature as the *O. Alexandrine* in the summer-time; but I like to remove it to a house just a few degrees warmer in our winter months, but it must always have a good supply of water, and also be kept in an atmosphere well charged with moisture. This species is found in New Grenada, growing at from 5,500 feet to 6,600 feet altitude, so that it does not reach so high as *O. Alexandrine*, this plant growing up to 8,400 feet elevation; consequently, *O. blandum* thrives better in a little extra warmth in the coolest months of the year. It is said to be constantly moist, and to be nearly perpetually in bloom, so that we have something yet to learn in the cultivation of this beautiful sweet-scented plant. It, like all the Orchids, is a lover of a free circulation of air, and by a judicious arrangement this can be accomplished in a much better style than the Belgians grow their Orchids on open stages, and which they see to claim so much credit for, by putting the plants into the houses below the pipes and

some ventilating caps on the roof, and if these are kept constantly open a delightful fresh atmosphere is maintained. I should like the Leeds Orchid Company to spare me one more flower from their plant in order that I may be sure of the name. I do not require more, and perhaps it would be as well if they dried it before sending. Now, a few more words in respect to its management. I have before stated the temperature I have found it to thrive in best. It is a plant that enjoys shade, so I like to keep it near the glass in a north-house, where it does not get any sunshine. The pot should be well drained, and the soil consist of good brown peat-fibre, and fresh and sweet Sphagnum Moss, and great care should be exercised in keeping any sour or stale stuff lying about it. MATT. BRAMBLE.

ODONTOGLOSSUM CERVANTESI.

A FINE spike of this beautiful old plant bearing five large flowers comes to hand from "James Brylen," asking if it is not *O. Rossi*? To which I must answer it is not, *O. Rossi* being a larger and bolder flower, its lip is longer, and the colour at the base of the sepals and petals is not displayed in such concentric rings as in the case of *Cervantesi* flower. This is one of the oldest species of *Odontoglossums* known, but yet it has not been grown as a living plant in our gardens more than about fifty years, having been first sent home here from the neighbourhood of Oaxaca, in Mexico, from whence it is found southwards into the neighbouring country of Guatemala, and the plants that come from the latter country thrive better with a little more heat than the same species coming from Mexico. It varies somewhat in colour, but the best named varieties which I know are *decorum roseum* and *punctatissimum*. The first-named plant has the lip of the flower deeply lobed and profusely streaked with purple; the sepals and petals are broader, and dotted with purple. This is a beautiful form, well deserving every attention, as also is the variety *roseum*, which has the colour of the sepals and petals of a soft rosy-purple, whilst in the variety *punctatissimum* the whole of the flower is spotted more or less with reddish-purple. In the flowers before me from "J. B.," the colour is of a uniform pure white, having a broad concentric ring at the base of the sepal and petals of reddish-brown spots. Now I suppose this plant flowering at the present time is caused by the wonderful season we have passed through, for I should imagine from the strength of the spike it had produced flowers before in the spring of the year (?) which more frequently is the time of its flowering. But, never mind; I have heard people say frequently that fruits and flowers are always prettier and more valued out of season, and I am sure that is so then *O. Cervantesi* will not lack admirers. This, as well as many others of the small-growing *Odontoglossums*, succeed best planted in shallow earthenware hanging pans, which should be well drained, and the plants should sit on a little mound of soil, which may consist of about half and half chopped Sphagnum Moss and peat-fibre, the whole to be pressed down firmly. The present species and its varieties enjoy good exposure to the light, therefore I used to hang them up near the glass in a north house; here they could remain all the day without shade, and in such positions I always found them to increase and to grow well and flower profusely, and to all of my readers I say—"Go thou and do likewise." MATT. BRAMBLE.

4886.—**Primula obconica.**—Handling these plants does, I believe, irritate the skin of those predisposed to skin diseases, but I imagine the number of these must be few. I have grown them for years, and find them most useful, both in the greenhouse and in the room, or for cutting, and I have never yet noticed a case of so-called poisoning by coming into contact with either plants or flowers. —E. H.

4877 and 4885.—**Flowers beneath trees.**—Try *Gaillheria Shallon*. It grows and spreads most rapidly under trees and shrubs, and is a handsome evergreen plant. Any soil but chalk or limestone suits it. —A. B.

4893.—**Nitrate of soda on a lawn.**—This must have been carelessly used, probably also in larger quantities than is necessary. About 5 lb. or 6 lb. to the square rod would be a heavy dressing. Though the Grass may be killed brown it is not likely to be killed. The roots will be damaged beyond use, and be decayed. No harm is done unless the nitrate has been rashly used. —E. H.

flowers of an exquisite rose shade. It is exceptionally free, and worth growing both outdoors and under glass.—C. T.

— This fine variety can be obtained from Mr. H. J. Jones, of Hither-green, Lewisham, who holds a large stock of this and others of the same class.—B. G. R.

EARLY AND LATE CHRYSANTHEMUMS.

If anyone is going in for Chrysanthemum culture with an idea of making a profit of the blooms he must look well after the flowers for the two extremes of the season—viz., the very early and the very late ones; not that they are better, or even so good, as the mid-season ones, but simply from the fact that there are so many of the mid-season ones grown for exhibition, decoration, &c., that everyone seems surfeited with Chrysanthemums, and no one appears to think of buying them. It is, however, quite different with the early and late sorts. This year, owing to the great heat and drought, there was a great scarcity of white flowers in September, and the early White Chrysanthemums like Lady Fitzwygram, Mme. Desgrange, &c., came in most opportunely; but mid-season sorts are so very numerous that one requires considerable forethought to time them to come in when they can be sold. But not so with the very late kinds, which are with us now plumping up fine buds, and any quantity can be sold at Christmas, and, as a rule, at very much more remunerative prices than can be made during November. It is rather singular that with almost all other flowers a month in advance of their usual season of flowering, the Chrysanthemum shows very little difference, and our late kinds still out-of-doors are only in the bud state. Similarity is with me the latest of all sorts, either new or old, one of the purest whites, and of the best and dwarfest habit of growth. There have been numerous additions to this useful class of recent years.

J. G., Gosport.

DEEP CULTIVATION.

It would be difficult to find a stronger argument in favour of deep cultivation than that afforded by the appearance of crops growing side by side during the summer drought, the one on deeply cultivated soil, and the other on such as has been merely dug over one spit deep; the one would be drooping, while the other would be vigorous and apparently enjoying the heat and drought, for the simple reason that the roots could penetrate in the deeply cultivated soil and find abundant moisture long after those growing in the shallow cultivated soils had exhausted their supplies; and this is the sole reason why allotment holders get so much heavier crops than the very same kind of soil yields when only ploughed over. And I would strongly insist all that have vacant land, which is not required for cropping until the spring, to deeply trench as much of it as possible; any kind of garden refuse can be utilised for burying at the bottom of the trenches, and no better use of cleaning one's land that has been allowed to get into a wretched state can be adopted than by trowling. Green crops are especially beneficial to hux in the soil, and old Strawberry beds are especially useful after many autumn rains to get weedy; but if the whole mass is turned in two spits deeps there will be no fear but that any crop put on next season will show good results, and after rapid cropping and frequent manuring, trenching is absolutely necessary to restore land to its fullest capabilities.

J. G., Hants.

HOUSE & WINDOW GARDENING.

CUT-FLOWERS IN THE HOUSE.

WINTER NOSEGAYS.

Our worst winter season gives us from a fairly stored outdoor garden much that a tasteful person can make beautiful use of. A charming bunch of winter flowers can be made up of the small and ordinary Christmas Roses, the brownish leaves of Ivy, a truss of Pyreanthin, a deep fringe of the large-leaved Saxifrage, and a few bits of the small silvery Eranthis and Laurustinus—all open garden materials easily got. In mild sea-coast districts, too, Anemones and other flowers that open during mild seasons are available, and if loosely arranged in a vase, as shown in the annexed illustration, they form a charming ornament to any room.—B.

— "E. Cooper" omits to say what arrangements he proposes to make for warmth in winter, without which cut-flowers for the house are not easy to procure from this time until spring arrives. Chrysanthemums can be made to yield plenty of bloom, if any sort of shelter, such as a south window, or a glass

taller old-fashioned kind, Brompton Stocks, Single Pyrethrum (excellent for decorative work throughout the summer), Madonna Lilies, Irises (both English and foreign), White Pinks (Mrs. Shikins being the finest kind to grow), and Iceland Poppies (most useful with their soft yellow tints). Roses, Carnations, and the host of summer blossoms will supply June and July, with plenty of Mignonette, Sweet Peas, Blue Cornflowers, Marguerites (both white, pink, and yellow), Gladioli, and Lilies in variety. August is the month for Asters and Dahlias, both of which should be grown in variety for cut-flowers, the

SINGLE AND CYCLOS DALLIAS being the best in cases. There should be a continuous supply of Shirley Poppies from early spring until frost begins, and this is easily secured by sowing seed in autumn as well as in spring, with successional beds to be sown in May, June, and at the end of July. These last will bring a blaze of colour into the garden during September and October, and be most useful for cutting when other things begin to fail. The writer has bouquets of them in the drawing-room at this date (November 4th), contrasting most charmingly with Pure-white Chrysanthemums from seed sown late in July. These Poppies need to be picked early in the day and when only half open; their delicate beauty will then be preserved in a cut state for several days, and few flowers are so light and elegant for table decoration, while their tints are singularly varied and pure. Japanese Anemones (both pink and white) are useful in September, especially Honoree Jobert (pure white, which, when well established in a shady spot, brings a great quantity of pure-ivory blossoms, exquisite for decoration). The early Chrysanthemums (Madame Desgrange, G. Wernig, La Vierge, &c.) can now be had from old plants, divided in spring and put into a sheltered corner with rich soil, and these with Dahlias, Pyrethrum, Asters, &c., will supply plenty of cut-flowers. After the middle of October Nicotiana glauca become valuable for cutting, and the ordinary run of Chrysanthemums, Pansies, and others, give a wide range of colour for cutting until Christmas, with slight shelter. In growing flowers for decorative purposes it should not be forgotten that suitable greenery is much needed to display them, and a few suggestions as to this may not be out of place. English Ferns of many kinds are very valuable for this purpose, especially Asplenium Adnigrum (nigrum) for small vases, as it is evergreen, and therefore available in winter, with Hart's-tongue (Scolopendrium vulgare), and the Common Polypody (Polypodium vulgare), which, however, needs damp wood in the soil to do well, as it grows on the branches of trees. An excellent substitute for Maiden-hair Fern may be had in the Common Yellow Fumitory (Corydalis lutea), with sprigs of delicate greenery, very Fern-like in effect, which last well in water, however. Even the more Common Purple Fumitory (Fumaria officinalis) is not to be despised in floral arrangements, the flowers being removed from the light, crowd-like sprays of foliage before using it. Plenty of ornamental grasses, too, should be grown, with a few good ornamental shrubs from which larger greenery may be cut when needed. Aucuba japonica, Berberis (Mahonia) Aquifolium, and Laurustinus are useful for the background of large vases with frolics of hardy ferns in the country can often find lovely sprays

OUR READERS' ILLUSTRATIONS: A bouquet of winter flowers. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. J. McWalters, Antrim, Ireland.

pond even (without heat) be available, lasting from October to Christmas, if both early and late kinds are grown. Without shelter they cannot be reckoned on after the first severe frost sets in. The only hardy blooms which can they be found in a garden are those of the Laurustinus, which is now in full bloom, and will continue to blossom throughout the winter in mild weather. Gray Violets, too, if grown in a sheltered spot under a wall, will bring many blossoms before Christmas, and the Yellow Jasmine (Jasminum nudiflorum) and Christmas Roses will also open in December after a mild autumn. January is usually quite flowerless outside; but in February the first bulbs appear, Snowdrops being better than Crocuses for cutting. March will bring plenty of Wallflowers (in a sheltered corner where cold winds do not blow), with Yellow Anemone, early Van Thed Tulips, Erica carnea, Anemones, Primroses in warm corners, and White Abyssians. In April the earliest open-air Dahlias (Narcosis) open, with Forget-me-not (Myosotis dissitiflora), Wallflowers in the open, Hyacinths, alpine Auriculas, and White Violets; the Devonshire Violet being one of the best of these. "May is the time" are proverbial, and include the sweetest of all scented blossoms. Lily of the valley, with Narcissus in great variety, Tulips of the

ing until Christmas, with slight shelter. In growing flowers for decorative purposes it should not be forgotten that suitable greenery is much needed to display them, and a few suggestions as to this may not be out of place. English Ferns of many kinds are very valuable for this purpose, especially Asplenium Adnigrum (nigrum) for small vases, as it is evergreen, and therefore available in winter, with Hart's-tongue (Scolopendrium vulgare), and the Common Polypody (Polypodium vulgare), which, however, needs damp wood in the soil to do well, as it grows on the branches of trees. An excellent substitute for Maiden-hair Fern may be had in the Common Yellow Fumitory (Corydalis lutea), with sprigs of delicate greenery, very Fern-like in effect, which last well in water, however. Even the more Common Purple Fumitory (Fumaria officinalis) is not to be despised in floral arrangements, the flowers being removed from the light, crowd-like sprays of foliage before using it. Plenty of ornamental grasses, too, should be grown, with a few good ornamental shrubs from which larger greenery may be cut when needed. Aucuba japonica, Berberis (Mahonia) Aquifolium, and Laurustinus are useful for the background of large vases with frolics of hardy ferns in the country can often find lovely sprays

of greenery with plenty of lily-like Grass and light berries for autumn decoration. The demand for these things is now so great that they may be bought in most good town markets; but if they have to be grown the various Barberries, Skimmias, Amelans, Hollies, the Snowberry (*Symphoricarpos*), the Winter Cherry (*Physalis*), *Cotonegus Pyramanthi*, and *Cotoneaster micranthylla* will supply excellent substitutes for flowers during the colder months of the year. —L. R.

1854. — **Malden-hair Ferns.** — These Ferns will not keep their foliage in winter in an unheated greenhouse, and would be sure to become shabby under the change from a warm room to a cold greenhouse at this time of year. If "Perseverance" means that they get no water from the time they are brought in until the week's end, this is probably another cause of failure of foliage. Ferns should never be very dry, especially when in a dry, warm atmosphere, such as that of a sitting-room, although at the same time they should not be soaked with water when the surface soil is damp. They also object to a draught, and should be placed in a sheltered corner, not too near the fire, when needed for decoration in a room. But they would be far better out of the room at night, an amount of the dust and draught which they must go through in the early morning, when the housemaid attends to the room. Delicate Ferns suffer greatly from the icy blasts which then go through the place for its necessary airing, with accompanying dust. The best plan is to remove the plants at night (before the lights are lit) either into a warmed greenhouse, where they can stand on a damp floor, or else into a bathroom with hot-water pipes, or a warm bedroom, covering them with a newspaper shelter, easily made with wire, paste, and double newspapers, of a size and shape to suit the plants. In a dry atmosphere they do best if a large tray or flat bath be laid on the floor for them at night, with a little water in it, and the pots are placed on inverted saucers, so as to stand over the water, but not with their roots in it; a paper cover placed over this will keep in the moist air, and save them from dust, too. Ferns feed much through their fronds, and never flourish where there is no moisture in the air, but they can be kept in health in this way, and may be used for decoration during the afternoon, if removed before the drying effects of the lamps or gas do them injury at night. —L. R.

TREES AND SHRUBS.

4885 and 4886. — **A Virginian Creeper.** I do not know if this is obtainable in England, but I see the name is in the "Tree and Shrub Catalogue" of Messrs. J. Veitch and Sons, Chelsea, and possibly they may have it. I do not know *A. japonica* Huggi, but as *A. japonica* is synonymous with *A. tricuspidata*, the kind popularly called Veitchi, I should say that it was different from the one I have under the name of muralis. "M. C." may plant it as soon as ever he can get it anywhere during winter or spring, as it is quite hardy. The few that I had planted on walls have been so beautiful that many more which were planted to climb trees but did not make much progress there have been taken up and planted against the wall. In case "M. C." and "H. P. H." cannot obtain the kind in England they will be able to get it from the same source, as our plants came from the great nurseries of Tramon Brothers, Orleans, France. —A. H.

I see that the variety muralis is advertised in Messrs. Veitch's catalogue. Their address is King's-road, Chelsea. This is the only nurseryman that, as far as I can see, embraces it in their selection of climbers. This is a good time to plant, and onwards to the end of winter. It is perfectly hardy and vigorous, but give the plants a good start by letting them have fairly good soil. —C. T.

1901. **Clipping Conifers.** — I think it is a mistake to clip Conifers at all. They look best when allowed to grow naturally. Especially is this true of *Cypripedium macrocarpa*. But if Conifers must be clipped, the best season is in May, and then the young growth will escape the spring frosts. —E. H.

Spring would be the best time; but why clip and hack the shrubs about as you propose to do? You do not see the natural beauty of the shrub which you are to improve, by pruning. —C.

FRUIT.

APPLES FOR SMALL GARDENS.

The time is more and more at hand for making selections of fruit trees for various purposes for planting during the coming autumn. Although it is yet too early to think of planting the trees, it is not too soon to order them. Nurserymen, as a rule, execute their orders in rotation, therefore those that order early stand a good chance of getting the best trees, as I do not suppose the worst trees are sent out first. There is now such a large number of varieties to choose from that there is not the slightest excuse for having those sorts that are worthless or even of moderate quality. As much space is required to

Apple "Red Calville."

cultivate an inferior variety, and very often more, because worthless sorts of Apples are frequently good growers. Where but a few trees can be accommodated they should be of the best kind, not only as to their individual quality when cooked or in a dessert state, but their merits as croppers ought to be taken into consideration. I have here growing over one hundred varieties, therefore can speak with a little authority on the subject. There are some varieties of Apples that will not succeed in certain kinds of soils, no matter how the planting is done, which renders the selection of sorts more difficult for universal acceptance. However, a safe plan to follow is this: Select those kinds that will succeed in congenial soil, and rest assured that those sorts will flourish in soil that is generally regarded as satisfactory for Apple-culture. In making these remarks I ought, perhaps, to name the two kinds of soil I take exception to. In the first place soil that is insisted to Apple culture

Apple "White Calville."

is that which is heavy in character, but not absolutely clay, yet retentive of moisture, and consequently cold during the winter and spring, and liable to come canker very quickly where there is the slightest disposition to this evil in Apple culture. Canker, in my opinion, is mainly caused by the frost affecting the non-ripened shoots of the previous year's growth, thus injuring the tender bark as a commencement of the trouble. Without experience of soil it is a most difficult as well as a risky thing to make a selection of varieties, but by following the practice advised of planting those sorts that flourish in congenial soil, but few mistakes are made. It is very annoying after spending time and money for half-a-dozen years

to find then that certain sorts are useless for a particular site. Soil favourable to Apple culture is that which is generally termed heavy loam, meaning soil that is slightly above the medium in point of adhesiveness, or, in plain words, more inclined to clay than sand. I purpose to place the varieties in their order of ripening somewhat, so that intending planters may be better able to select, according to the season they require much or little fruit. Opportunity is then given of reducing or increasing the number of trees of any particular section. Dessert varieties: Irish Peach and Devonshire Quarrenden, August; Lady Sudeley and Worcester Pearmain, September; King of Pippin, October; Cox's Orange Pippin, November; Bannan's Red Reinette, December; Sturmer Pippin, January; Fearn's Pippin, February. Kitchen varieties: Lord Grosvenor and Duchess of Oldenburgh, August; Bellinville and Stirling Castle, September; Frogmore Prolific, Golden Spire, and Warner's King, October; Lane's Prince Albert and New Hawthornden, November; Bismarek, December; Brandley's Seelling, January; Newtown Wonder, Sandringham, and Alfriston, February; New Northern Freezing, March. In sunny and cold districts Apples are worthy of a place against a wall or even under glass, and good kinds for these purposes would be the Red and White Calville (here figured) Ribston and Cox's Orange Pippin, or any of the Nonpareil type. S. P.

4905. — **Apples and Pears in a greenhouse.** — Yes, with free ventilation both Pears and Apples may be permanently grown and fruited in a cool green or orchard-house with perfect success, though if the trees can be removed to the open air for a few weeks after the fruit has been gathered so much the better. As far as I have seen, the most successful results are obtained, at any rate in dealing with Pears, by planting single cordons along one or both sides of the house, and training the stems on wires 10 inches or 12 inches from the glass. If the house is sufficiently wide, a central bed may be occupied by bush trees of Apples, Peaches, &c., in large pots or tubs, or even planted out. Still, they will do very well as bushes or pyramids in pots or tubs. Two excellent Apples for this purpose would be Cox's Orange Pippin and Lane's Prince Albert, and two fine Pears Knills d'Herst and Doyenne du Comice. — B. C. R.

4903. — **Gooseberry-caterpillar.** — The present is a good time to take away the soil from under the bushes. It should be removed to the depth of 3 inches or more, and fresh earth put in its place. It may interest this correspondent to know that at South Hill Park, only a few miles from where the inquiry was written, the gardener has laid the short Grass from the lawn under the Gooseberry and Currant-bushes in preventative, and I never saw a caterpillar on them. The Grass was used for this purpose from the commencement of the mowing season until the close. Mr. James, the gardener, never claimed for his practice a cure for the destruction of these insects; all he knew was that since he commenced laying down the Grass he had never been troubled with them on bushes so treated. It would appear that there is something in the denying Grass that is unpleasant to the caterpillars if there be any there. We must, however, remember that these insects appear to possess a kind of migratory character, as they are very much in evidence one year and absent the next. — J. C. C.

Now is a good time to prune the bushes, cutting away any weak branches, so giving more space to those that are stronger. Especially thin out the middle of the tree, admitting light, air, and sunshine to that part. Any shoot of last year's growth not required for furnishing the tree in the future with branches should be cut back to one or two eyes at the base. If the trees are beyond eight years old remove 3 inches of the surface soil for about 2 feet from the stem all round, replacing it with fresh. If the trees do not make much growth add decayed vegetable refuse, partly rotted manure in a sixth part, mixing with it some quick-lime. Next February paint the branches entirely over with diluted cow-dung and clay, in about equal parts, worked into the consistency of paint, adding at the time of using the mixture some fat from the

kitchen refuse; this added when hot prevents the other ingredients being washed off by heavy rains. An ordinary paint-brush is the best way of applying the mixture; it may be rather a slow process, but it is a sure one. Not only does the mixture act as a preventive to the caterpillar, but it also cleanses the branches of Moss and Lichen. Should a few caterpillars make their appearance the spring following, dust the parts affected with Hellebore powder, and vigorously syringe the trees the following morning, bearing in mind that the powder is poisonous. It is perfectly harmless if syringing is properly done with clean water.—S. P.

4377. — **Moving Apple-trees.** — Apple-trees will move with safety now. It is not necessary to wait for the last leaf to fall. It is always advisable to save as many roots as possible; but the bruised and lacerated roots should be cut back to sound wood.—E. H.

— This is the best season of the whole year for planting or moving Apple-trees, and the quicker the work is done the better, so as to let them get fairly established before the winter. Many delay until spring, but this is most certainly not good practice, as the trees are commencing to push forth growth again, and this is checked. It does not matter about the leaves being green. Foliage has kept on longer than usual this year, and a few sharp frosts will soon bring it down.—C. T.

4398. — **Pruning a Vine.**—If the vine has a fruitful habit the side-shoots may be cut back to two buds or eyes. As the vines are old the canes need not be cut back at all. The leading shoot at the top will, of course, be shortened back to three eyes or so. I am assuming the vines have filled the house.—E. H.

POTTING BULBS.

At this season of the year many amateurs are anxious to try their hand at growing bulbs of various kinds, the ordinary Dutch bulbs being the greatest favourites, notably Hyacinths; and as the bloom-spike is already formed, one would think it were almost impossible to fail; nevertheless, plenty of failures do occur, and, as a rule, they may be traced to too much kindness. The following plan never fails, provided the bulbs are good, and it may be taken for granted that unless the bloom-spike is already formed in embryo, no amount of high culture will make one—at least, for that year. For

Outdoor ones or borders October is the best month for planting, and as the beds are then being cleared of summer bedding plants, the first thing to do is to deeply dig the beds, breaking the soil down fine; then take your bulbs, and with a trowel place them in the position they are to flower in, covering with from 2 inches to 3 inches of soil. If the soil is naturally of a porous, sandy nature there is no need to place fresh sand over the bulbs; but in stiff soils it preserves the bulbs from stagnant moisture. After planting is completed a covering of about an inch of Cocoa-nut fibre greatly protects the bulbs from frost, but it also gives a vent aspect to the beds, and it is a very cheap article.

For culture is probably the most satisfactory way of cultivating Hyacinths, Tulips, or Narcissus, for as they are naturally very early flowering plants, our variable springs frequently spoil the finest displays, but even a cold-house or pit renders them safe. In potting the first consideration is to get good bulbs, not only large of their kinds, but especially well ripened, for on this hinges the size and quality of the bloom. Then prepare the soil, and I find nothing suit bulbs better than turf that has been stacked one year. If this is chopped up, and a little rotten leaf-mould and sand added, it will develop them to the fullest extent. After potting place them on a dry, cool ash-bed, and cover the pots with the same material or Cocoa-nut fibre, but do not put them into a warm-house or pit until the pots are full of roots and the tops have started into growth, for this is the most frequent error that young beginners make. They push the top growth up before the roots are ready to support it, and as a natural consequence they fail, and generally blame the bulbs, instead of their mode of culture. In window-boxes many bulbs are planted, and, as a rule, they succeed well, provided the winter is not extra severe; but it should be borne in mind that during very severe frost the soil in window-boxes will get frozen right through, and the roots of the bulbs will suffer. As a safeguard, an extra depth of Cocoa-fibre should be placed over the bulbs, or the boxes transferred to a *Dahlia* *Gaulthery* *fruit* breaks.

JAMES GROOM, Gosport.

THE KITCHEN GARDEN.

FORCING RHUBARB AND SEA-KALE.

MANY amateurs are deterred from growing Rhubarb and Sea-kale-roots for forcing, by reason of the exaggerated difficulties in the way of forcing, whereas it is one of the easiest things in the whole round of the year to have a good supply of both Rhubarb and Sea-kale from Christmas up to the time when it comes in naturally, and, as a rule, Christmas is quite soon enough to get the first batch ready, for it is during the first three months of the year that anything in the way of forced vegetables is most welcome. In starting a supply of these things, the first thing is to prepare a large supply of roots by planting single crowns of Rhubarb at a yard apart, and letting them grow without any disturbance to the leaves during the summer, as they will develop several large crowns, and yield a quantity of stalks when forced. Sea-kale can be increased to any extent

Rhubarb "Victoria."

by seed, or pieces of root cut into sets, and planted out in rows two feet apart, and the sets one foot apart. At this time of the year they will be ready for forcing. A deep box set in any warm place, such as under the stage of a hot-house or in a warm stable—in fact, any position where heat is obtainable; set the roots at the bottom of the box, cover them with soil, and give a good soaking of water, and cover with hay or straw to exclude the light, and the produce will be fit for use in a month or six weeks, according to the heat at command. A succession can be easily managed, and as the season advances, the quicker the produce will come ready for use.

J. G., Hants.

4338. — **Carrots for show.**—Two good sorts for exhibition are James's Scarlet Intermediate, of which there are many "improved" varieties offered, and St. Valery, the latter being a first-rate medium-sized exhibition variety. Seed sown in light, rich soil in a warm situation in March or April would produce good exhibition roots in July. They should be grown on land that has been previously

mumured for former crop (that on which Ch-luges have been grown suits them admirably), as freshly-mumured land tends to produce grubby and forked roots.—B. J. P.

NOTES ON TOMATOES.

WHETHER on account of a largely-increased consumption, or because the production has certainly not exceeded, even if it has equalled, the average, certain it is that the price of Tomatoes has kept up in a quite remarkable manner, especially considering the character of the season, during the whole of the past summer. The market price as quoted in the weekly reports (I am quite aware that this is by no means a positive guide) did not fall below 6s. per lb. during the entire season, while a considerable grower in South London told me recently that he had sold none under 8s. per lb. retail, or 5s. when disposing of them to the local shopkeepers. If the Tomato revels in sunshine to the extent that all the recognised authorities would have us believe—and there is really no doubt about it—then it has been an ideal season for this particular crop, both under glass and in the open air. But there is a good deal of difference between a fair amount of sunshine, as experienced in an average English summer, and over four months of constant and downright blazing sun, without enough rain during the whole of that time to properly dry the dust. This is what we had to undergo here, though in many parts, I believe, it was not quite so bad. During the whole of March, April, May, June, and August also, everything here was as dry as the Desert of Sahara, the sky like brass, and the earth (our stiff, clay soil, at any rate) but little less hard than iron. Unless constantly and copiously watered, nothing could or would grow either indoors or out, and in many other instances, the house supply of water was short, and large quantities had to be brought a considerable distance. Such a state of things not only increased the labour and cost of production largely, but rendered the risk and proportion of failures much greater also. Some, or one might safely say many, growers, however, obtained good—even unusually good and heavy—crops, but at the same time an exceptionally large

NUMBER OF FAILURES of one kind or another have come under my notice, not only in this particular district, but all over the kingdom. Where the plants were healthy and vigorous from the first, and received correct treatment (considering the unusual character of the season) the returns have been excellent, but when through either ignorance or accident errors in cultivation were perpetrated, failure in whole or part has been the inevitable result. In some cases, either through the necessary amount of water having been "skirked," through a mistaken idea of the requirements of the plants, or from actual scarcity of water, the plants were really starved, while in others an excess of moisture has been given; while a very common mistake has been made in an excessive use of the syringe, combined with insufficient ventilation. This kind of thing invariably ends in a bad attack of disease; but there is a certain class of men who cannot learn, or believe that the methods they have always practised can possibly be wrong. Complaints of the blossoms dropping instead of forming fruit have been very numerous, but in nearly all cases they seem to have resulted from errors of treatment, the plants in some instances having been unduly starved, but more generally over-stimulated by means of rich soil, excessive watering, and a too close and moist atmosphere, especially before a certain amount of fruit had been formed. This, of course, absorbs any surplus energy, and, as a rule, effectually prevents the plants "running away," or making a more or less rank and fruitless growth afterwards. Herein lies, indeed, one of the secrets of successful Tomato culture—I do not say to starve the plants, but to carefully avoid throwing them into anything like strong or rank growth by means of either much moisture, atmospheric or otherwise, or manure, or in other words to "keep them well at home" during the early stages, until a certain stage of productiveness has been reached. After that they may, and indeed must, if an abundant crop is to be realised, be "fed" to an extent that few other subjects require, and would endure. The amount of water and liquid-manure that a

healthy and prolific Tomato-plant growing in well-drained and not too deep border, box, or even pot, demands, especially under the tropical sunshine of the last summer months, is almost incredible, and, indeed, under the circumstances named it would be difficult to afford too much. With reference to the peculiar and apparently unaccountable "flagging" disease, or rather affection (for I am now of opinion that it is not a disease) which has been mentioned more than once in GARDENING, and of which several other instances have come under my notice during the last two or three years, I may say that I have suffered from it rather badly the last two seasons, and believe that I have at last arrived at the cause, which is simply to be found in the quality of the water employed. I meant to have written this on the subject some weeks ago, and, indeed, commenced to do so, but have not had time to finish until now. However, farther experience and observation have developed in my then somewhat crude ideas into almost positive certainty, so I trust they will be by so much the more useful. Being here a good many miles from any water-works or mains, where in rain falls for more than two or three weeks at the outside, and the supply of soft water fails, we have to go to the neighbouring ponds, brooks, or springs for the necessary fluid. Ever since I came I have noticed that after having this kind of water for any length of time, the indoor plants of all kinds did not grow as freely as they should and usually do, and after a time assumed a white and starved appearance, but until quite recently I never thought of connecting this fact with the way in which many of the

TOMATO-PLANTS FLAGGED under the influence of a hot sun, and after a time in many cases collapsed entirely. Thinking it might be the fault of the soil, I tried them in earth of all descriptions, both light and heavy, rich and poor; tried keeping them comparatively dry and watering heavily, and also the result of almost all the manures and stimulants extant, but all to no purpose, so at last noticing that whenever a few showers or a thunderstorm enabled us to use rain-water for a time things began to improve in appearance all round, I came to the conclusion that the water, and this alone, was to blame, and this is now proved beyond a doubt. I have since been treating the water with a chemical preparation, with the result that a quantity of fine, slimy, yellow deposit is precipitated from even apparently perfectly clear and pure fluid. This I take to be clay in a finely-divided state (we are on a wide belt of solid clay of the heaviest description), with probably iron in some form as well. In passing through the soil, which acts, of course, as a filter, the water leaves this finely-divided and evidently poisonous matter behind, and it chokes and cripples the roots, with the result already described. A still farther proof is that I never had, or even saw, this affection until this and last year, when of both the spring and early summer were dry, and in 1891, when it rained frequently or constantly throughout, I had in the same house, and under the same conditions, a splendid crop, although the plants were not put out until May, and had no fire-heat whatever. Wherever this affection occurs growers should look to the quality of water employed, and, if possible, get it analysed. I am glad to see that at least some amount of attention is being paid to the quality and flavour of Tomatoes, in which respect the different varieties vary to an extraordinary extent. I have always studied this point carefully, and for some years past have been endeavouring to obtain a Tomato that would combine the prolific and free-setting qualities of the old Large Red with compact and short-jointed habit of growth and superior substance and flavour. Up to the present Perfection is, all things considered, the nearest approach to this happy combination, but then the growth is so very long and strung as to render it unsuitable for low houses or frames, while unless happily circumstanced and skilfully treated it is certainly not the best of setters. Conference is extra dwarf, free, an excellent setter, and of good substance and flavour, but the fruit is rather too small, both for market and home use, to meet the taste of most consumers. A local variety called *Sixes Beauty*, of which I don't know the parentage, is good all round, but not quite up to my standard, and the American variety that I have seen in the

obtain are in my experience more or less useless here, whatever they may be in the climate of the States. Considered from this point of view, many of the most prolific varieties, and notably King Humbert, also known as Chiswick Red, are wretched things, devoid of both substance, weight, and flavour. Challenger (which appears to be very similar to the old Tennis Ball, possibly slightly improved) is but little better. I think that when judging Tomatoes at shows, the adjudicators should cut some of the fruits across, so as to show the substance, or want of it, even if it is not tasted, as in the case of Melons. I may, perhaps, be allowed to add that one or two of my seedlings exhibit an unusual amount of solidity, with very few seeds and a rich, sweet flavour, while the habit is extremely short, and the fairly large fruits freely produced. Of one I have a golden character from a large Jersey grower, to whom I sent a few seeds for trial. Owing to the circumstances described above I had only a limited quantity of fruit, and that was late. Much the finest crop of Tomatoes I saw this year was in a nursery in the south of London (that of Mr. H. J. Jones, of Lewisham), where the plants were a perfect picture, being laden with large fruit of perfect form and finish. Every bloom had set, and each plant, I was told, would produce between 20 lb. and 30 lb. of fruit by the end of the season. The variety chiefly cultivated is an improved form of Perfection.

B. C. R.

ONIONS FOR WINTER USE.

THESE are in great demand in winter with all families, large and small, and therefore must be

Onion "Pear-shaped Spanish."

had in good condition. The great point is to thoroughly ripen and harden the bulbs by full exposure to sun and air after lifting. The weather in September of this year was excellent for that purpose. Where they were taken in roughly to be cleared on wet days, proceeded with, and finished so far as seems possible, all would be well. Any with thick necks, or that made a second growth, and which seem to be in consequence almost in two parts, should have been put in one side for immediate use, as they will not keep until spring. Others of extra large size may also be placed amongst these, for it is only medium-sized bulbs of good form and great soundness which should be stored away for use in spring and early summer. The common flat White Spanish types, though otherwise excellent, are not such long keepers as Bedfordshire Champion, and a good strain of the Pear-shaped Spanish Onion, such as James' Keeping, which should always be left to the last. I rarely ripe any of my Onions. They look well in that way, but that is all. I find they keep equally well without the trouble of tying if simply laid out in a thick layer on shelves, or on the floor of a dry, cool room or shed. Properly stored Onions do not decay readily, and they are not injured if exposed to a few degrees of the frost if perfectly dry. Mine hardly fail in that way until they begin to grow, which is not until April or thereabouts.

specimens of this were shown last season weighing 30 lb. Golden Ball, fine globe-shaped variety and splendid keeper. Cranston's Excelsior, grand globe-shaped; for weight and shape, combined with keeping qualities, this Onion has no superior. Trebons, a fine large exhibition variety, equally good for autumn or spring sowing. Magnum Bonum, grand distinct variety. Bedfordshire Champion, oval-shaped, and Giant Zittau, both good varieties and splendid keepers. Sow the seed under glass in January. In March prick off to boxes, and in April plant out in land which has been deeply trenched and heavily manured the previous autumn. If you find the grub attack them, as is often the case, sprinkle the bed with coarse salt, which will not only prove beneficial, but also act as a manure to the roots.

—E. J. P.
1893.—Treatment of Rhubarb.—The best treatment for Rhubarb at this season is to touch round the circumference of the roots with good manure, adding a forkful of manure rather longer over the crowns. This covering makes the crowns dry earlier, and it is ready to gather a week or ten days before anything can be had from the unprotected crowns. —E. H.

THE HOLLYHOCK AS A GARDEN FLOWER.

ALMOST every cultivator of the Hollyhock could speak or write about the difficulties he has had to contend with in dealing with this, the most stately of the hardy flowers that adorn the garden in autumn. Some timid amateurs are overcome with the first signs of disease on the plants, and have not energy enough to make anything like a strenuous effort to overcome it. I find a great deal depends upon the weather. The year before last the disease was very troublesome. I had to give a lecture on this flower that year in August, and at the time some of the plants were quite covered with the fungus, many of the leaves being totally destroyed, others far gone, and the entire collection diseased to a great extent. I have grown some of these plants this year, others were added to them, and they have flowered splendidly. Although the disease appeared in the spring, it did not spread after May, and the plants are practically free from it. I made no attempt to destroy the fungus, and yet, owing to what I may fairly term the incidence of the season, a good bloom was obtained, and the plants now seem as if they might be propagated freely for next season's flowering. I have not yet touched the plants; they still remain in the open border, but in October or November they ought to be lifted and planted in flower-pots of a suitable size, or what answers us well, plant them out closely together in an ordinary garden frame, and give them sufficient attention in the winter to prevent the leaves from damping off. I cannot severely winter my Hollyhock plants unless I get them under glass in some way. I find even in frames, with the continual fogs now London, the leaves are constantly dying off, owing to mould getting upon them through their being almost constantly damp. If the plants are putted up and flower-pots placed on shelves near the glass roof of a house from which frost is merely excluded by artificial heat, they are not injured in the least; but here, again, we have to face the readiness with which the plant is attacked by the disease under these somewhat artificial conditions, and again, comes the time of propagation, when the plants, or rather the cuttings, have to be placed in a forcing-house, and the chances are that even if there were no traces of fungus before it will appear now. We cannot help ourselves; the cuttings must be put into heat, and the addition of bottom heat, with a rather close atmosphere, is necessary. We may expect the appearance of the fungus, and I saw a good specific for it is sulphur stirred up in soft-soapy water, about 2 oz. of soft-soap to the gallon of water; too much soft-soap injures the leaves; 4 oz. of sulphur may be used. The sulphur has a tendency to sink rapidly to the bottom of the water, and must be constantly stirred when the leaves are being dipped. Another plan which has been found quite as effectual in removing the parasite is to dress the affected parts with Cundy's fluid, using a soft brush to apply the liquid. When the cuttings are rooted they must be taken out of the hot-bed and be placed on a shelf near the glass in the same house; this causes the leaves to become more crisp, and if the cuttings have been placed in flower-pots they may be

reputed into 3-inch pots, and when the plants have taken hold firmly of the new potting-soil they may be removed to a much cooler house, and subsequently to a cold frame. The propagation of the plants and preparation for planting out are important parts of their culture, and the point to attend to as of most importance is to keep the leaves clean, free from the fungus, red-spider, and thrips, as it is only by thus caring for the plants that they can be kept steadily growing. Care must also be taken not to allow them to receive any check at the time of their removal from the warm-house to a greenhouse (temperature or from the greenhouse to an ordinary garden frame.

Some cultivators of hardy plants may wonder that it is necessary that so much pains should be taken with a plant comparatively hardy. To this I reply that although the Hollyhock is a much hardier plant than the Dahlia, it cannot be so freely propagated. The cuttings take longer to form roots and growth is slower afterwards, and unless the spring cuttings are propagated as advised, they would not form roots in time to give good flowering plants, or they might not bloom at all. The preparation of the ground is also of much importance, and this should be seen to in the autumn. The Hollyhock is a gross feeder and requires a deeply worked soil with a good dressing of farmyard-manure, and when the ground is trenched up in the autumn the winter weather prepares it for planting in April or early in May. The young Hollyhock plants should have been well inured to the open air before planting them out, and the operation of planting should be performed when the weather is mild and the ground dry. The permanent sticks must also be placed to the plants at the time of planting out; indeed, it is much better to drive the sticks firmly into the ground before planting, and dig out a hole at the front of the sticks into which should be placed some prepared soil, such as is used to pot Pelargoniums, to give the plants a start. The plants must be tied to the sticks as soon as they have grown a little, and it is a good plan to mulch around the roots with a little decayed manure; this keeps the soil moist, preserves a more equable temperature over the roots, and the plants will make a much better growth. As the season advances, dry weather will set in and water at the roots will be needed, but it will also be desirable to syringe well underneath the leaves to keep off red-spider. The first appearance of the fungus is the signal for an attack upon it; if it is taken in time some good may be done, but when it has spread widely over the entire collection of plants, the case is hopeless. It requires a good stout stick to hold a well-grown Hollyhock plant in position, and as the spikes advance in growth, they must be securely fastened to prevent their being snapped over in a high wind. A good strong plant will throw out many side growths, and it is usual to remove these so that all the strength of the plants may be thrown into the centre spike. Upon the side growths there are also numerous flower-buds, but at the base of each there are a few leaves with leaf growths at their axils; all these may be taken and cut out as Vine eyes are treated for propagation, and if inserted singly in a small flower-pot, they will soon form plants in a very mild heat if covered with a garden frame. The dead and decaying flowers should be removed from the plants, as they not only have an untidy appearance, but they also cause the seed-pods to decay. Seedling raising is also an important and interesting part of the cultivator's work. I sow the seeds in May, and they form strong plants for flowering the following season. They may be sown out-of-doors, or, what is better, in a frame over a hot-bed. The seeds are more likely to vegetate well in that position, and the seedlings can easily be pricked out into boxes to be transferred to the open borders as soon as they are large enough. They ought to be planted where they are to flower in good time so that they are well established before the winter. Seedlings are seldom injured by frosts. J.

poured over them will kill all its touches. Pieces of raw meat or bones from which the meat has been cut has a wonderful attraction for them, and the bones could be dipped in hot water occasionally, when the insects are crowded upon it. Poison is sometimes used. Arsenic mixed with treacle is effective; but, then, such mixtures are extremely dangerous. Carbolic acid will kill them, and a strong solution of Sunlight soap, 6 oz. or 8 oz. to the gallon, will destroy any insects. —E. H.

GARDENS IN JAPAN.

There is in Japan a calendar of flowers, and each month has its festival. In March it is that of the pink Plum-blossoms; in April the Cherry-trees are in bloom; in May all the hillsides are aldaze with the Scarlet Azaleas, and the Wisterias are hanging their long lilac blooms over trellises in the Tea-gardens, or from the trunks of trees in the woods; in June the tall Lilies and Irises (see illustration) are scenting the air; in July the Peony-gardens are visited for the sight of the exuberant blooms; in August the lovely Lotus covers all the muddy pools with splendid flowers and leaves, and laddens the heavy air with sweet perfume; in September the Maple reddens the mountain-sides; later the Chrysanthemum heralds the winter, which is also not devoid of flowers, for before the frosts and snows have disappeared the red Camellias, growing on

Its time in a Japanese garden. Engraved from a photograph sent by Mrs. Ernest Hart.

trees as large as our Hawthorns, are brightening the woods with their ruddy blooms. (Of this p.

WISTERIA-GARDENS I must say one word. It was in May, the month of months all the world over, when I went one brilliant Sunday to Kanmibu in Tokio to see the famous Wisteria-gardens. These gardens are situated on the confines of the temple grounds, which are always the scene of the happy innocent amusements of the Japanese, their religion and their worship not being of the kind to induce to gloom and apprehension, but leading them to make the best of everything in the best of all possible worlds. A bridge, which describes more than a semicircle, and which it is one of the mild jokes of the place to traverse, connects the temple grounds with the Tea-gardens. The bridge spans the narrow neck of a pool or pond, around and overhanging which are set the booths where the happy people picnic. The garled and twisted branches of the ancient Wisteria-trees form the roofs, and under the flickering shadows of the long lilac blooms, which hang in abundant masses 2 feet and 3 feet deep, the light-eyed *misses* and the winsome children sit on their heels eating sweetmeats out of little lacquer picnic boxes; or leaning over the parapets they clap their hands, at the sound of which huge golden carp as large as salmon-treat lately come to be fed with biscuits and bonbons. Words fail to convey an idea of the brilliancy of the scene. The radiant air, the luxuriant wealth of flowers, the soft brilliant colors of the women's dresses, the many, many lanterns, the laughter, the gaiety, and

the careless happiness of the whole combine to make a scene never to be forgotten. The

ART OF GARDENING is, however, cultivated in Japan not only by public bodies, or solely as a means of providing public amusement and recreation, for it is an art dear to the heart of every inhabitant of the land of the Rising Sun! Every Japanese, however poor he may be, however small may be his house, strives to reserve some little space which would be in England relegated to the uses of a backyard, dustbin, and rubbish heap, to the laying out and cultivation of the traditional garden. This is, as everything else in Japan, unique. In the traditional garden should be found a miniature stream flowing between rocks, bordered by one or more tiny stone bridges and bordered by low Pine and other trees, which are not allowed to grow their own sweet way, but are trained to bend and reach at strange angles over the shallow stream, in the water of which a few tame carp are always to be found. Blossoming trees and shrubs fill up the space, and among them is always to be seen the stone lantern, in which on certain occasions a lamp is placed, with the object, it is said, of lighting the soul back to its old home on earth. In many such gardens, adjoining the paper-walled workshops where the patient Japanese produce their marvels of art workmanship, have I had the processes of manufacture explained or demonstrated to me, or the objects brought out to be photographed. But small as are most of the gardens in Japan, like the people and their houses, and expressive as anything else of the refinement, the absence of care and the repose of their lives, there are yet many gardens and parks which are as extensive as those in England. The great enclosures of the Daimies during the old rule of the Shogunate, most of which have become public parks, the silent groves around the Shiba Temples, and the extensive gardens of the Mikado's palace at Tokio testify to the fact that the Japanese can conceive and carry out a grand scheme of a garden. Among many

BEAUTIFUL PRIVATE GARDENS I may mention, however, that of Count Matsura at Tokio, which was a celebrated garden before the city of Tokio was built. Here a lake takes the place of a pool, and forest-trees overshadow the blossoming Cherries, and a tea-house and bath-house bear witness to the thorough enjoyment of life in a garden. In Japan, though flowers are adored, hot-houses are unknown. With a taste as correct as it is refined, the Japanese do not aim at cultivating the rare, the costly, and the novel, but at taking the common flowers of their country occurring in their natural sequence, and by care and cultivation making them the sources of national enjoyment. Thus the Cherry-trees in Ithome, which in England can only be seen in our kitchen gardens, are deemed in Japan a sight worthy of the Mikado to invite his guests to view. If.

INDOOR PLANTS.

4880.—Fuchsias from seed.—Seedling Fuchsias are not more difficult to raise than other plants. Sow the seeds in heat in spring; pot off when large enough, and treat the same as plants raised from cuttings. The probabilities are the seedlings will not be altogether like the parent. If you have saved seeds wash them out of the pulp at once, dry and place in a paper packet till spring. Keep the soil about dry through the winter, and warm it up in spring, there will then be young shoots break out that will make the best possible cuttings. Under good treatment seedling Fuchsias will flower the same season if helped in heat in the spring.—E. H.

—This is a very simple matter, all that is necessary being to wait until the berries or fruits are ripe and of a deep blackish-purple colour; then wash or rub out the seeds in sand, sweet them in a dry place, and sow in well-drained pots of sandy loam and leaf-mould in February, placing them in heat, of course. Prick off the seedlings singly as soon as they can be handled. Transfer them singly to small pots when fit, shifting them on into the 3-inch size, in which they will bloom during the succeeding autumn. But plants thus raised from seed will not come true to the parent plant. Cuttings are very easily

4837.—Destroying ants.—There are several ways of destroying ants. Boiling water

of the women's dresses, the many, many lanterns, the laughter, the gaiety, and

struck, though it is almost too late now; but with a very little care there is no danger of losing a healthy plant if wintered in any frost-proof place.—B. C. R.

4896.—**Camellias losing their buds.**—I think that "W. N. G. L." is keeping the roots of these too moist in comparison with the atmosphere. The temperatures given are all right for plants under forcing; but this grand greenhouse shrub will not bear hasty forcing, nor do they like a dry atmosphere at any time, least of all when the blooms are expanding. Buds of Camellias will drop very freely from slight causes, and it may be that the plants have been too dry or too wet for a short period. Syringe them occasionally, and so soften the buds somewhat. This often aids them considerably.—P. U.

— This is a common question at this season of the year, and a frequent complaint of amateurs. It is simply the blight of summer, and results from neglect during the late summer days, when it is thought the plants are at rest, and therefore require little or no attention. I often see plants absolutely dust-dry, and it is foolish to rely upon showers, as these simply moisten the surface of the soil, and that underneath is quite dry. A Camellia is a plant that does not quickly show signs of neglect, and is apparently healthy when almost dying. At any rate, this drooping of the buds is due to this cause, but I hope you will not lose all the buds. Pay careful attention now to the watering, giving no more than necessary, and avoid a hot atmosphere.—C. T.

— The temperature is too high, and the plants do not get enough water. Give more water, and put a little stimulant in it. Soot-water is good for Camellias. Do not let the night temperature rise above 50 degs.—E. H.

4899.—**Semi-double White Ivy-leaved Pelargonium.**—No; there is no white-flowering variety in this section at all equal to Mme. Crousse and others in habit of freedom and flowering, etc., and anything of the kind would be a great acquisition. The two best whites so far are La Candeur and Sarah Bernhardt, but neither of these are quite pure, and they are on the whole poor things compared with some of the others. Congo, Mine Cochin, and A. F. Barron are the nearest to a true lilac shade, and Alice Crousse, Daniels Bros., and Cavier are, perhaps, the best among those with magenta-coloured blossoms.—B. C. R.

— There are a number of beautiful varieties, and a good double white is Candeur, the plant very free, and of vigorous growth. Jeanne d'Arc is a fine kind, the flowers white, touched with a lavender shade, and other varieties worthy of mention are Beauty of Castle Hill (rose), Rycroft Surprise, a new kind, a cross between Mme. Thibaut and Souv. de Chas. Turner, the flowers salmon-pink in colour, and the plant very free and vigorous; Edith Owen (rose magenta), La France (lilac), the habit dwarf and free; Souv. de Chas. Turner, one of the best of all, the flowers produced in large trusses, and of a pink colour, with maroon on the upper petals; Galice (rose-pink), Congo (pale-lilac), Mme. Thibaut (pink), and Le Printemps (rose-pink), a beautiful variety.—C. T.

— There are no semi-double Ivy-leaved Pelargoniums as good as Mme. Crousse. Jeanne d'Arc is a very useful variety, with white, sometimes lilac-tinted, flowers; but it is not so free in habit as Mme. Crousse, and the flowers have shorter stalks and are not so useful for cutting. Congo and A. F. Barron have lilac-tinted flowers, and are in their way very good.—E. H.

4903.—**Eucharis and Amaryllis.**—The temperature named would suit the Amaryllis, but though the Eucharis Lilies may be kept in a night temperature of 55 degs., they will do very much better when the thermometer does not fall below 60 degs. Water should be given according to requirements, and most plants will use up more in a warm house than in a cool one. During the resting period the Amaryllis bulbs are kept quite dry, but water is given again when there are signs of movement. The Eucharis is an evergreen, and will not bear drying off in the same way as the Amaryllis, but a partially dry treatment is useful at times for its resting effect. The Amaryllis flowers in summer, sometimes earlier, sometimes later. The Eucharis may be made to flower at any season by varying the resting periods. Those who have plenty of bulbs need never be without flowers.—E. H.

4881.—**Foliage Begonias.**—The best newer varieties in this class are Bertha

MacGregor (leaf long, pointed, and notched, centre dark, with broad silver zone, and narrow margin of bronze); Decora (dwarf, with small leaves and stems, leaves bronzy-olive, marked with greenish-yellow along the midrib and nerves); Dr. James (leaves satiny greyish-white, with dark-green margin and veins); Flora Hill (small leaves, body colour green, irregularly splashed white); François Buchner (large heart-shaped leaves of light-green, edge bronzy-red, pearly-white zone); Mme. Cholet (bronzy-green, with silver blotches); Mme. G. Bruant (leaves deep metallic green, with purplish-red centre and white blotches); Mme. Putry (ground colour, white, with rose markings, and purple and black margin); Mme. P. N. Binot (centre dark, zone silver, and broad margin of purplish-green); Mrs. A. G. Shepherd (broad leaves, centre and edges bronzy-red, remainder of a silky-green hue, beautifully shaded); Mrs. E. Bonner (light silvery-green leaves, margin and ribs, bronze-red, fine habit); Perle Humfeld (leaves velvety green, shaded, with zone of bold silver spots or blotches). Six good older kinds are: Comtesse Louise d'Erdozy, Diademe, Distinction, Louise Cluson, Mme. Amagny, and Mme. Selbecq. All, or nearly so, of the above can be obtained of Messrs. Laing and Co., Forest-hill, or of Messrs. Cammell and Sons, Swanley.—B. C. R.

4885.—**Begonia seed-pods to dry.**—You may ripen the Begonia pods by pulling them in a shallow pan of sand and placing them where they will get the full benefit of the light and sun, either on a shelf in your greenhouse or in the window of a warm room. When thoroughly dry the seed may be cleaned by rubbing the pods through a fine sieve or a piece of muslin.—E. J. P.

4888.—**Violas in winter.**—If there is no danger of overcrowding the plants in the frame allow the runners to remain; they will give good blooms later on when the bulk of those from the plants are over. When the plants are put into the frame the leaves of one plant should just touch those of its neighbour, then there is no fear of overcrowding.—S. P.

RULES FOR CORRESPONDENTS.

Questions. Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters in business should be sent in the Postman. The name and address of the sender are required in addition to any designation he may desire to be used in his paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent in press some time in advance of date, they cannot always be copied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their respective departments) should always bear the number and title placed against the query copied to, and one answer will generally suffice us for ordinary queries, or for as brief knowledge and observation permit. The correspondents who seek assistance. Conditions, such, and means very so irregularly that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4917.—**Japanese Anemones.**—Will anyone kindly inform me when to plant these in a garden?—K. M. P.

4918.—**Himantophyllum splendens.**—Will someone kindly give me directions for culture and treatment of this plant?—A. M. P.

4919.—**Spring Onions.**—I should like to know whether Spring Onions will do best on a Carrot-bed or where?—Gelling has grown?—Novice.

4920.—**Cinerarias in a cold frame.**—Should Cinerarias in a cold frame be watered overhead through a rose pot at this time of the year, or watered at edge of pot?—Hector.

4921.—**Pruning Fig-trees.**—Will someone kindly tell me whether Fig-trees should be pruned now? An old Fig-tree I have is now full of a new crop of fruit. Should these be taken off?—BALDROCK.

4922.—**"Malmalson" Carnations.**—I have some "Malmalson" Carnations in a greenhouse, and they have brown spots on their leaves. What is the matter with them, and what is the best remedy?—NOTICE.

4923.—**Grafting or budding Cherries.**—I have this autumn dug up several Wild Cherries and planted in my garden. To obtain fruitful Cherry-trees ought I to graft them, or bud them next spring?—C. W. G.

4924.—**Lawn-sand.**—Will anyone give me a good recipe for making lawn sand for a large lawn that is much covered with Moss and Ferns? The sand is mainly loam. Will nitrate of soda and sand suit?—F. H. Chrétien.

4925.—**Pelargoniums, Tea Roses, &c. for market.**—Would anyone please to inform me what I should keep on for such plants as Pelargoniums for early market, and for Tea Roses and Callas?—EDWARD TUNNICLIFFE.

4926.—**Cape Gooseberry.**—Will someone kindly tell me if the Cape Gooseberry is a good market fruit? Could it be grown with profit in a forcing-house, where an early market; also where seed could be obtained?—J. S. WEAVER.

4927.—**Early Tomatoes for market.**—Will someone kindly inform me when the first sowing of Tomatoes should be made for next year's crop? I would like to have them into the market as soon as possible.—JOHN DICKSON.

4928.—**Sulphate of ammonia.**—Will someone kindly explain for what vegetables sulphate of ammonia is good? Also the quantity to be used, and if dry or in water? Is it good for any flower-roots—viz., Chrysanthemums, &c.?—Cook.

4929.—**Aspidistra.**—How many varieties of Aspidistras are there? Does the variegated variety ever flower; and, if so, what is the best treatment to attend it? Can you give any directions for the general management of Aspidistras in the house?—C. CURFMAN.

4930.—**Plants for a shady spot.**—A part of my garden is shadowed by tall trees, and I should be much obliged if someone would give me a list of under-shrubs and hardy flowering perennials suitable for such a position? The shade is partial, not dense.—CERAMUS.

4931.—**Aphis on Chrysanthemums.**—My Chrysanthemums have been covered more or less all the season with a little black aphis, which clings to the stems. I keep removing it, but it soon appears again. Will someone kindly tell me the cause and the best way to get rid of it?—B. M. P.

4932.—**Fruit-trees in pots.**—My master has bought some newly-potted fruit-trees (Peaches, Nectarines, Plums, and Pears) for an unheated house. Not having grown any before in pots, I should be glad to know if I should keep them dry or moderately wet? The house is as cool as possible.—S. S. B.

4933.—**A garden hedge.** My house fronts a road, and has a plot of garden ground between. I am planning a Laurel hedge, but until it grows up it will need other protection from publicit. Will someone please suggest a few tall flowering plants to grow inside the Larches?—J. C. BIRMINGHAM, M.D.

4934.—**Roses for pegging down.** I am about to form a bed of Roses with an idea of pegging them down. At what distance apart should they be planted, having in view the well-being of the Roses as well as economy in space; or should I obtain a little offset from a bed of Lauras planted closer?—BYOONA.

4935.—**Heights of Chrysanthemums.**—Will someone kindly give me the average heights of the following Chrysanthemums, grown without topping? La Spaulding, Etiole de Lyon, President Hyde, M. G. Levesley, W. Tricker, W. Coles, Mes. A. Wright, Mrs. de Levin, George Daniels, Mons. Bernard, Violet Tomlin, Mas M. Haegras.—CHRISTY VICAR.

4936.—**Unhealthy Weeping Ash-trees.**—Will someone kindly tell me how to treat two unhealthy Ash-trees? For the last two summers it has made hardly any growth and very scanty foliage, and seems falling. As I have a pair of them on my lawn I am most anxious to save them, and should be greatly obliged for information on the subject.—S. W.

4937.—**Ferns not thriving, &c.**—I have a small store-house, containing principally Ferns. These are well thriving, the foliage being of a pale, delicate green. Will someone kindly state the probable cause, and also what ventilation and watering such a house should have at this time of year? Also whether a large and busy conservatory should have daily ventilation?—ISQUIRE.

4938.—**Lilies in pots.**—Last year I had some Lilium reginae (Queen's) given me, which I planted out. Next year I should like them in pots, so have taken them up to dry. Should I break off the little offsets, and plant them out, or in pots, or will they be best dried with the old bulbs? I, of course, should like to increase them, and do not want to waste the little offsets.—BALDROCK.

4939.—**Scotch Firs.**—I am proposing to cut off the lower branches from a row of Scotch Firs. I have done so for several winters past, but each year the trees seem to bleed or exude more resin. This year the branches are so thick that I am afraid of bleeding the trees to death, so appeal for advice. Is there much danger of killing the trees? What is the safest time to cut them?—AMATEUR.

4940.—**Plants for a herbaceous border.**—Would someone kindly give me the names of about twenty plants suitable for herbaceous border? I would like good flowering kinds that would not grow higher than 2 feet on an average. I may say I have planted bulbs of sorts in it, and want these to partly form a background. Being a reader of GARDENING this last eight years, I am sure you will assist me.—ALLANBARDA.

4941.—**Vine-roots going down.**—I should be glad to know the best way to encourage the roots of Vines to the surface of the border? My land being rather heavy they have a tendency of getting to the bottom of the border—I mean inside of the house. Also, would the present time be right to lift them carefully? The Vines are now about seven years old. Any information on the above subject I shall be glad with.—F. C. C.

4942.—**Gas-tar on hot-water pipes.**—Will someone kindly say if gas-tar on hot-water pipes causes any injury to the plants? I have just put in a hot-water apparatus in my new greenhouse just erected, and I was advised to use the pipes with gas-tar in present run, but I find the plants are being burnt considerably. Is this the cause of the tar on the pipes? If so, can I do any thing to prevent this?—A YOUNG ENGINEER.

4943.—**Japanese Chrysanthemums.**—I shall be very much obliged if any one can tell me the name of some Japanese Chrysanthemums now growing out-of-doors in London gardens (November 1st). They are a brilliant bronze-colour, and I see, are being a great deal sold in the streets. I should also like to know the name of a very large cream-coloured Japanese Chrysanthemum now growing out-of-doors in London?—M. R.

4944.—**A bushy Rose, &c.**—Will someone kindly tell me the best bushy Rose to grow in a mixed border against a north wall about 5 feet high, or a Fuchsia to answer the same purpose? I wish it to grow just above the wall, so as to take off the strain of the line; but do not want a too showy one, one that would have to be kept constantly cut back at the centre of flowers. I get a little a stake, but that never buds. Rose is more suitable subjects.—J. GLENN.

4945.—**A garden in Surrey.**—I shall be very grateful if someone will tell me what to do with a garden in Surrey on a slope facing south-west, with the sun on it all day? The soil is very sandy, and when any deeper than one spit is sand-rock, either soft black or yellow clay. A lot of fruit-trees were planted by a nursery gardener, but, so far, in three years have made no growth. What should be done with them? Also, how ought the borders to be prepared for flowers?—M. B.

4946.—**Early-flowering Chrysanthemums.**—Will someone kindly give me a reliable list of early-flowering Chrysanthemums for outdoor work in Yorkshire, not including *Mine*, *Desgrange* and her sports? This year, if ever, Chrysanthemums should have flowered well outside; but William Holmes, Lady Selborne, Plymouth (and I think), and Mrs. Cullingford, all called "early-flowering," have failed to get beyond the bud stage with me. They were planted out in a rich border in May. —*CORSTAR VICKAR.*

4947.—**Valiota not flowering.**—I have had a *Valiota* for three years, and it has flowered each autumn, but does not make any growth. During the summer it has about seven or eight leaves, and directly it has done flowering about three or four of these turn yellow and drop off. It is kept in a sunny window, with a fire all the winter. This year it has not flowered at all. Should this be so? I see other *Valiota* plants large and full of leaves. I have not repeated it since I had it. Any information will oblige. —*A LOVER OF FLOWERS.*

4948.—**Early Strawberries.**—I have about 250 strong plants of Nobles and Paxtons, grown in 5-inch pots which have been for the last three months in a trench in my garden filled with Cocoa-nut-bark. I want to know the future treatment for forcing? When must they go into vinery? I have a hanging shelf that will hold about 50 pots some 18 inches from the glass, and another shelf against a wall at back of vinery. Will they require heat, as I do not want to force *Vines*? Should I take all the quantity into house and approach of hard weather, or only a portion of them, as I want to see them in flower in rotation? I do not want them to fruit until the season is fairly on. Any information will oblige. —*AMATEUR.*

4949.—**A kitchen garden near a river.**—My kitchen garden runs alongside a river, the normal height of which is about 2 feet 6 inches below the lowest level of the garden; even in very high floods the water never comes into the garden. The soil is sandy. I propose to protect the river side of the garden with 10-foot high barbed paling. This will have an aspect east by south. I am anxious to cover the fence with fruit-trees—Pears and Plums for choice. For about how many trees would there be room in 30 feet length? What inexpensive precautions, if any, would be recommended to prevent the roots getting into the water? What sorts would be likely to thrive in such a situation? What would be about the latest safe date for planting? In fruit I infinitely prefer flavour to size and appearance. —*REVEREND QUERY.*

REPEATED QUERY.

4948.—**Ferns for a heated conservatory.**—Will someone kindly tell me what Ferns and Mosses will suit a conservatory, moderately heated by hot-water pipes up to 60 degs. It is on the south side of the house. There are glass panes, with windows above and at the sides to open, size 20 feet by 7 feet. I live in Bayswater, London, and wish to grow some large hardy Ferns high up, and some smaller and fairly delicate Ferns low down among the tufts, which forms a rockery overhanging a pool. There is plenty of *Platanus*. Will *Smilax* trail up the wall in this conservatory, or does it require more moisture?—*PASIR.*

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4950.—**Cypripedium Leeanum.**—*H. Hubbard* sends a flower of this fine hybrid, but it is a very poor form of the plant which has become a great favourite. Your flower appears to have so much green in the dorsal sepal, and the rest of the flower is very dull coloured. I cannot congratulate you upon your success.—*M. B.*

4951.—**Lycaste Skinneri alba.**—*Ben Hardy* sends me a flower of this chaste and beautiful variety. It is not so large as I have seen, but the contour of the bloom is charming, and being so broad and full. "B. H." asks me to tell him something about this family? I cannot do so this week, but I will endeavour to shortly.—*M. B.*

4952.—**Indian Filberts (S. J. T.).**—These seeds which you inquire about are sold in London by this name. The seeds are contained in large, flat, woody pods, which grow from four to six feet in length, and are the fruits of *Eutida scandens*. It is a native of tropical America, and the natives of these countries convert them into spoons, snuff and Tobacco-boxes. The seeds, although large, are not edible.—*J. J.*

4953.—**Adiantums.**—*G. Gubbin* sends what I have always known as three distinct kinds under the one name plant of *A. hispidulum*, and he asks if these are all the same? Now the broad marked 1 is *Adiantum julium*, 2 is *Adiantum tenellum*, and 3 is *A. hispidulum*. You will see a great difference in the shape of the fronds in 1 and 3. The frond marked 2 is more like 3; but in its size it always keeps constant under cultivation whatever it may do in a wild state, and I have always maintained the three to be distinct kinds.—*J. J.*

4954.—**Cypripedium insignis punctatum violaceum** (No Name).—This is the name of the variety sent, and not the form known as *Mauli*, after Mr. Maul, of Bristol. This is a bolder and, in my way of thinking, a far superior flower. It is quite astonishing the number of fine varieties of *Insignis* that are cropping up nowadays, making this old species quite a gay and desirable plant, and I wish to see you to my residence there is a collection with several hundred flowers now open, which make quite a splendid appearance.—*M. B.*

4955.—**Cypripedium Arturianum (G. Gloze).**—I cannot compliment you on your skill in cultivating this seedling. It is certainly the most beautiful I have ever seen; but I strongly feel the necessity of bringing forth such a fine form of it as you send, and I should imagine it

must have been a fine form of *C. Insignis* which you took for the parent, for it is an excellent variety of the above hybrid, which was obtained first by the Messrs. Veitch, and it was named by Reichenbach in honour of one of the members of the firm. Your flower has a wonderfully long dorsal sepal with a very white top.—*M. B.*

4950.—**Repeating Orchids (J. Benson).**—You do quite right to ask these questions in good time. You say you have taken my advice, and repotted your *Odontoglossum* and cool *Oncidium*. Now get some peat-fibre and some sphagnum moss plucked, and keep it in the house ready for use. All the plants will not require potting or repotting at the same time, so that in the case of one or two coming on with their wants and requirements you will have nothing to stop you from doing it at once. The advantage of keeping material in the house with the plants ensures you from injuring the roots with cold soil.—*M. B.*

4957.—**Oattleya calumnata (John Godefroy).**—I read your letter before seeing the flower, and I came to the conclusion that it was not likely to be true, for the plant is too expensive to be in the collection of a working Amateur. It is a supply one of the parents of *calumnata* (*C. Arabialis*), and if you paid anything like a price for this raised between *C. intermedia* and *C. Acanthis* by M. Bleu, of Paris, and it is certainly a most beautiful hybrid; but it appears to differ from most of the garden hybrids in being of a bad habit of growth, whilst the most of garden hybrids are very free. Your flower is an ordinary form of *C. Acanthis*.—*M. B.*

4953.—**The Sage Palm.**—*W. Williams* sends a penately-cleft woody leaf, on which are borne the seeds of the *Cycas revoluta*, and which will be of no use whatever, because it require to be fertilised. These plants are really not Palms at all, but are members of the *Cycadaceae*, and in Japan and China a kind of starch resembling *Sago* is obtained from the pith. You have a beautiful ornamental plant, and one that will not rapidly grow too tall for your house, although it does require watch to spread its leaves. Do you require to cut the old leaves away? This is the plant used by the Saxons to do honour to the dead, and a leaf was used in the same manner as we use wreaths and crosses.—*J. J.*

4959.—**Lælia Dormaniana (Catherine Edwards).**—This is a pretty variety which this lady sends for a name. It flowers for the first time some fourteen years ago in the garden of the gentleman whose name it bears. It does not appear to vary greatly, and this does not say much for the supposition of its being a natural hybrid; and yet I have seen it imported in great numbers. The sepals and petals are bronzy-green, streaked and flushed in the flower before me with purple. The three-lobed lip has large side-lobes of a rosy-purple, and the middle lobe is of a very deep and rich amethyst-purple. Its native home is in the mountains about Rio de Janeiro, at some 2,000 feet elevation. It is a very pretty little plant, having slender stems growing about 1 foot or eighteen inches high, usually bearing a pair of leaves, and it is because the thin stems become dry and leafless on their journey home that the plants have such a paltry and mean appearance that it has not yet received the attention at the hands of growers to which I think it is entitled.—*M. B.*

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to me should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—*C. M. Mayor.*—Appears to be *Rubus australis*.—*J. P. Sorlie* underland.—1, *Nephrolepis exaltata*; cannot name the others from leaves only.—*H. B.*—The numbers of two were off; but I think this is how they were with the very dark edge to the lip. 1, *Lælia Perrini*; 2, *Lælia Dayana*; 3 and 4, varieties of *Cattleya Lohrbachii*.—*L. Stauffer*.—1, Cannot name from infertile fronds; send again; 4, *Polystichum Wollastonii*; 5, *Lastrea Niebohl*. The others had no numbers; send again.—*T. W. S.*—We cannot make anything of your *Cypripediums*, for when they arrived they were all without a spot or marking whatever.—*W. Horbin*.—1, *Adiantum hispidulum*; 2, *Polystichum angulare* prolixum; 3, Not recognizable; 4, *Ditto*; 5, *Ladies Cudston* is *Armeria vulgaris*, but cannot recognize the plant you send; 7, Send when in flower.—*B. Williams*.—*Cycas revoluta*.—*Catherine Edwards*.—*Lælia Dormaniana*.

Names of fruit.—*Quat.*—Pears all Autumn Crascae.

POULTRY AND RABBITS.

4826.—**Keeping Pigeons for table.**—Try the cross of *Dragoon* hens and *Cherry* cocks. Hens will breed well up to five years, and cock birds when of generally finish off their young better than younger birds. Feed the old birds on equal quantities of brown Peas, Tares and Indian Corn, leaving the last out after Christmas, as it makes laying hens too fat. When the young can peck give them Indian Corn.—*J. B. R. P.*

The common Cote Pigeon, sometimes called the Blue Rock, would be the variety I should recommend. You should procure some young birds from two or three lofts, and thus ensure a cross from the first. There may be some exhibition varieties which would answer, but the probability is they would not breed as rapidly as those which have been accustomed to harder fare. Pigeons rarely grumble at any food which may be offered them, especially if they are accustomed to the food from the first. Peas are useful, but I find they relish anything which the hens will eat, such as soft foods of various kinds, Wheat, Buckwheat, Barley, and the like. They like mortar rubbish to peck at and will also

readily pick up small pieces of rock salt. For breeding Pigeons I should use plenty of meal, as this is passed on at once by the old birds to the young ones in the nest. Pigeons breed for several years and need not be changed every year like fowls. If I were about to make a start with Pigeons on a large scale I should take care to keep an exact record of the birds hatched in each year, so that the birds could be distinguished at any time on examining their legs. Pigeons will feed as often as their feeder cares to throw them corn. I should be content with twice daily, and let them do a little foraging on their own account. I cannot speak positively as to the number of pairs which may be bred in each year from one set of birds, but this year I have known a flock of birds increase from two (that is, a cock and hen) to eighteen. I believe two pairs of the young birds have nested on their own account, and I have reason to think that another nest is being made. I do not think this could be looked upon as an average return, especially if a large flock is intended to be kept. The pair of birds to which I have referred were about to nest last Christmas when the remainder of the flock were sold; they were therefore kept and have had the use of a large Pigeon-house, in which they have not been molested either with rats or other Pigeons. I am not prepared to say that Pigeons (the common kind) will not pay in any case, but, as a rule, I believe they do not. I have already said they are tremendous eaters; they are ever ready to drive away chickens from their food, and when any favourite corn happens to be stacked within easy reach of their cote, they are constantly engaged in pulling out the ears or pods. Another obstacle to profitable returns is the constant shooting which goes on when the birds take a daily turn in the neighbourhood. On several occasions I have seen them return with a broken limb, and there is no doubt that many are ever ready to shoot at any game which comes within their reach. It is right to point out these things to "Blue Rock," so that he may not be disappointed. If he merely looks upon the Pigeons as a hobby he will not be so particular about the expenses exceeding the receipts.—*DORLING.*

4827.—**Keeping fowls, &c.**—It is difficult to advise in cases of this kind. If the bird were active last year, and good broods of chickens were hatched, there is no reason why the same success should not be forthcoming next spring. It would undoubtedly assist to secure this end if the bird were now separated from the hens, and be made to pass the winter in a roomy run, where he could get plenty of attention, and not be permitted to fall off in condition. The two birds should certainly ensure an abundance of fertile eggs. If the old bird were not reliable last season there can be no encouragement to keep him for another year, and in that case I should certainly sell. I am not particularly partial to cross-hen cocks, although I have met with some which were very useful, and begot good chickens. The Rock and Houdan cross should answer, large birds, good table fowls, tinted eggs, and plenty of them, as well as little trouble from excessive broodiness, all being possible to secure if good strains are selected for the parent birds. With regard to "Ivy Bank's" fowls, the quiet omits to mention whether any chickens, and, if so, how many, have been bred during the nine months. This alone can determine the question whether the returns given is a good one or not. We may consider the nine months' average to be one hundred eggs per hen, and there are still three months to run, during which few eggs can be looked for. I should not look upon the average as a good one if the hens had done no sitting; but even in that case it is not wise to pass an opinion, because the pullets should have done some work in the three months immediately preceding the 1st of last January. October is the first month in the poultry-keeper's year, and the returns should be given from the beginning of that month to the end of the following September.—*DORLING.*

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner and will appear in due course in

BOULTON & PAUL, MANUFACTURERS, NORWICH.

PORTABLE WOOD & IRON BUILDINGS
FOR LEASEHOLD PROPERTY
Cool in summer; warm in winter; can be inhabited the moment they are finished; no possibility of damp.

Shooting and Fishing Boxes, Gentlemen's Residences, Stables, Coach Houses, &c., Game Larders, Gardeners' & Labourers' Cottages.

Descriptive Catalogue of all our Manufactures, including Iron Buildings for Shooting and Fishing Lodges, Stabling, Huts, Kitchens, Laundry Appliances, Greenhouses, Garden Frames, &c., free on application.
Families, amusees, and additional recommendations to visiting dwelling houses mentioned.
Testimonial from Herbert Greg, Esq., Sept. 13, 1893: "I am pleased to say the work was done very well, and I think I should it will be very comfortable when finished."

THE NEW TUBULAR OIL HEATING STOVE

(HOT WATER AND STEAM)
FOR CONSERVATORIES, POULTRY HOUSES, AVIARIES, &c.
Superior Oil and Gas Furnaces.

Prices 45s.
55s.
70s.
95s.

Write for Price List.

The introduction of this stove marks an important advance in the method of heating Conservatories, Poultry Houses, Aviaries, &c. It surpasses all existing systems, particularly the old and uncertain one of furnaces with the necessary stoking at all hours. It is simplicity itself, and, like simple inventions, is almost self-acting. As will be seen by the illustration, the stoves made upon this principle are constructed on the tubular system, but they differ from any others in that the tubes are heated partly by hot water and partly by hot air and steam. The hot air and steam tubes become hot immediately after lighting the burner, and the hot-water tubes soon after. The ordinary stoves are fitted with a flue and a tall chimney. The large have special heat giving burners. Stoves 5 ft. 4 in. long and under are supplied with a coal boiler, when over that length is required, these tubes are supplied to any required length which can be fixed by avoiding travelling to the distance required. There is an inlet with wheel gear provided to run off waste products, so that for Conservatories, Poultry Houses, &c., these Stoves are absolutely impalpable, and they contain, moreover, a Superior vessel for keeping the air properly moist. For efficiency, economy, and cheapness these Stoves are unrivalled. It is important, when writing for information, to give all the information possible as to the dimensions of the conservatory or greenhouse required to be heated, with particular as to aspect, connection with house, &c., and a rough sketch is always of assistance.

RICHARD EVENS, 43, BAKER-ST., LONDON, W.

HEATING APPARATUS,

GREENHOUSES.

AMATEUR.—Span-roof, made of well-seasoned red deal in a strong, substantial manner in sections, and can be put together by any handy man or gardener in a very short time. Complete with ventilators, iron for opening door with lock, stages for plants, all glass fitted and marked to proper places. 7 ft by 5 ft., 4s.; 9 ft by 6 ft., 4s.; 12 ft by 8 ft., 5s.; 15 ft by 10 ft., 5s.; 21 ft by 14 ft., 10s. 6d. Strong Garden Lights, 2 ft by 1 ft., 1s.; 2 ft by 1 ft., 1s.; 4 ft by 3 ft., 1s. 6d. each; 16 ft by 4 ft., 5s. 6d. each. All securely packed on rail. For illustrations of above and price of other sizes, send for Complete Catalogue, post free. Estimates free for every description of Horticultural work.

J. JAMES,
355, High-road, Chiswick, London.

GLASS WIRE HYACINTH SUPPORTS. Made of flat wire, best quality. 2s. 6d. per dozen, carriage paid on 1 dozen and upwards. E. F. JAMES & CO., Wireworks, High Bridge, Newcastle-on-Tyne.

FAWKES' SLOW-COMBUSTION HEATING APPARATUS

Most Efficient and Cheapest in Existence.

Requires no work at all and no brick setting. Will last all night without attention. Will burn house coals, therefore works next to nothing for fuel. Anyone can use it. A domestic servant can stoke it.

SUCCESS GUARANTEED.

Thousands of these in use all over the country.
ONLY SLOW-COMBUSTION APPARATUS OF THE KIND

CAUTION.—Reverse of instructions. Incomplete apparatus which will not last all night.

Full particulars and prices of every sized apparatus and numerous testimonials for hot fire seasons, showing enormous success, post free on application.

Complete Apparatus from £4 12s.

BEST CONSTRUCTED and CHEAPEST Greenhouses
Ponding Houses, Pits, Frames, Plant Protectors, Potting Sheds, Tool Houses, &c.

Illustrated Prospectus sent post free from
CROMPTON & FAWKES, CHELMSFORD.
NO FLUE REQUIRED.

CHRYSANTHEMUMS.

THE BEST NEW VARIETIES.

So many take an interest in Chrysanthemums now and grow the newest kinds that I have made notes of the more important novelties worth getting to add to any collection. All the newer additions, at least those for exhibition, bear very large flowers—in fact, a small or even medium bloom is useless in competition. It is overshadowed by the monsters, measuring sometimes nearly a foot across. This is a false taste, but as readers want to know the best varieties, their names and a brief description of each are here given.

JAPANESE.—Of this class, amongst the whites the first is unquestionably *Mlle. Therese Rey*, a large, handsome flower, pure white, the florets broad, but not coarse, like so many of this section—*Waban*, for instance, a much-praised novelty, but far too coarse and ugly to grow. There seems a perfect plague of these monstrous, big kinds, and why they are grown is a mystery. This former variety is French, but many of our most beautiful novelties are raised by English growers, a few by Americans, but it seems likely that in the future the majority of the best Chrysanthemums will be English seedlings. *Golden Wedding* is likely to prove the best of the yellows; the flowers are large but refined, the colour deep-golden-yellow, and the florets incurved slightly. It is a sturdy grower and in all ways a fine Chrysanthemum. *Chas. Davis* is a sport from *Vivand Morel*, that peculiarly sportive variety, which is pure-white on early buds, and later blooms display various shades of rose-lilac. The sport *Chas. Davis* has bronze-yellow flowers, and the petals reflex, more so than the parent. It is a good grower. *Lord Brooke* is classed as a reflexed Japanese, and is a very fine flower. It is very large, full, and when in perfection more like a giant incurved than a Japanese. The colour is very rich and beautiful, bronze-yellow, with a more distinct orange margin to the broad florets. *G. C. Schwabe* is a full, handsome flower, colour carmine-rose, the centre of a golden shade. *Col. W. B. Smith* will be as much grown as any Japanese kind. The habit of growth is like that of *Avanduche*—that is, dwarf and vigorous, and the flowers are of pleasing colour—old gold, shaded with terra-cotta, a distinct tone. I have seen many fine blooms of it this year, and it has been shown in all the leading stands. Excelsior is of a different style; the flower is stiff to a fault, but very full, solid, and striking, the florets broad, cherry-rose colour, and somewhat incurved, showing a silvery reverse. *William Seward* has not shown to advantage this year, but this is due, I think, to hard propagation. There has been a great demand for it, with the usual result—the plant is propagated "to death." Those flowers in free stands I have seen have been very fine, as much for form as for colour, a deep-crimson, not unlike that of *F. A. DeWitt*, but with another very fine dark-coloured variety, remind-

ing one in aspect of *Val d'Amloré*, the colour deep-crimson, a superb shade. It is quite a relief to see such kinds, and I hope raisers will get good decided colours. The poor, washed-out colours of many novelties is objectionable, and such kinds are lit only for the rubbish-heap. *Gen. W. Childs* is a variety that seems very poor. It is not worth buying as yet, although might be better next year. At present it is far inferior to many older varieties. *Beauty of Exmouth* is worth noting, the flowers are very refined, and the white florets curl and twist about in a charming way.

A few years ago much interest was shown in the hairy or hirsute class. *W. A. Manda* (yellow) and *White Louis Boelmer* are beautiful, the latter far more so than the daisy type. It is better far, in my opinion, than *Mrs. Alpheus Hardy*, which is a miffy grower, whereas the other is vigorous and the flowers solid. They are pure white, opening of a primrose tint, and very hairy, if that is any special recommendation. It is synonymous with *Enfant des Deux Monts*. *Miss Dorothy Shea* (terra-cotta), half reverse. *R. Flowerlay*, the florets crimson and with silvery reverse. *Duke of York*, crimson, and *Mrs. Harriet Payocare* good acquisitions, the flowers large, of a rose-purple colour, the reverse silvery in colour. *J. Sunborough Dilbeek* (yellow to bronze) is a splendid kind. Many new kinds have been certified quite recently, but will not be in lists yet, and, therefore, it is of little use describing them. The incurved Chrysanthemums are getting much more numerous, and we have now some really fine things amongst them, which make this class more interesting. At one time it was chiefly the *Queen* family that was grown, until one got tired of the same colours and style of bloom. *M. R. Buhant* is a good French variety, although we do not like the same dark rose-purple colour. It has, however, been much shown this year, and is likely to be popular because strong in growth. *Brookleigh Gem* is of note for its rather distinct colour in this section, the flowers neat, and lilac-pink in colour, shaded with white. It is scarcely decided enough, but is shown well this year. *Lady Hemtel* is excellent for exhibition, and *Mrs. Robinson King* has been shown very freely this year. It is a sport from *Golden Empress*, the colour richer than in the parent, the flowers well shaped and neat. *Ami Histo* may be mentioned, the flowers buff in colour, with a purplish shade. There are some kinds that are really both incurved and Japanese incurved. *Robert Camell* is a case in point, a reddish-bronze colour, and the same may be said of *Mrs. Libbie Allen*, which, as I saw it a few days ago, was distinctly incurved the colour clear yellow. It is rarely difficult to advise upon this section. The shoots often turn out very similar to the parent, and one must exercise extreme care in purchasing. In the various other sections, a very good Anemone kind is *Mme. Nathalie Bram*, the colour sulphur-yellow, with disc and ray florets. *Kate Wells* is a reflexed Pompon, the flowers of a crimson shade, with the petals topped with golden-yellow. A very distinct Japanese Anemone kind is *John Bunyan*. It is quite new and worth recording as a fine acquisition to a small but

pretty class. The flowers are yellow, brighter in the centre than the guard florets. *Mrs. C. J. Salter* is a delicate self-bluff-coloured Anemone. I shall mention a few others as they are exhibited that I think worth noting by nurseries who grow the Chrysanthemum largely. There are now so many new varieties that the utmost care is necessary in selecting only those of real merit. F. P.

4931.—Aphis on Chrysanthemums.—Tobacco-wash and soft-soap—3 oz. of soap and 1 quart of Tobacco-liquor to the gallon of water—will kill black-fly, which are more difficult to destroy than green-flies. Tobacco-powder dusted over the infested parts, if taken in time, will be effectual. There is no lack of remedies if there is no procrastination in their use to keep down flies with ease. If the plants are not too large they may be dipped in a tub of wash made by dissolving Sanlight soap, 3 oz. to the gallon of water, used warm; better still the soap in the water.—R. H.

— This is one of the troubles of the Chrysanthemum grower. In doors or out-of-doors the aphid attacks the plants, and it is found on the young growths now starting from the roots, from which the cuttings are to be obtained for next season. Dip the cuttings in a solution of a little soft-soapy-water and Tobacco-liquor before planting them; and if it appears on the young plants when they are under glass, fumigate them with Tobacco-smoke. The insects will appear on the points of the growths when the plants are out-of-doors, and are usually destroyed by dusting with Tobacco-powder.—J. D. E.

— This is the Dark Aphid or Goldfly (Aphis fabae), which has been unusually troublesome this season. The best remedy is Tobacco, dipping the affected shoots in, or syringing the plants with an infusion of the fat, or the diluted liquor may be employed.—B. C. R.

4943.—Japanese Chrysanthemums.—There are many bronze-coloured varieties, but no doubt the kind is *Source d'Or*, *L'Isle des Plaisirs*, or one of that class. *Source d'Or* is one of the roughest, the flowers being produced with great freedom, and their bronze, orange, and chestnut colour is very rich. *Source d'Or* is a good market flower, and I notice it is being sold largely in the streets. Possibly the other variety is *Mrs. Randle*, which will do out-of-doors, but the white flowers get sullied in wet seasons. The time to plant is the spring.—C. F.

— Probably the bronze-flowered Chrysanthemum is *Source d'Or*, and the creamy-white may perhaps be *Lady Selborne*, as it is much grown.—E. H.

4946.—Early-flowering Chrysanthemums.—The varieties mentioned are really the October-flowering indoor kinds; but I have seen them blooming well out-of-doors. It is possible, however, the position does not suit the plants, and you are a good way north, where flowers are naturally later than in the south. This year in the northern counties the Chrysanthemums have been very late. My advice is to rely upon *Mme. Desgrange* and its sports, which bloom before the frosts. Three flower from August to October: *Alice Butler*, a sport from *Lyon*, red, with an orange shade in the throat; *Blushing Beauty*, a very bluish-coloured

Pumpkin; Early Blush, very early, bluish; Golden Shag, splendid yellow Pumpkin; Piercey's Seedling, bronzy-yellow; Lyon, deep rose-purple; Mlle. Loni Lassali, creamy-white; La Vierge, pure-white; and Précoce's, bright yellow.—C. F.

— This has been a very bad season for all of this class, probably the most un-remiss; but it will not be always so. As a rule, all those named do well and bloom beautifully. So far north you will find the true "early" or summer-flowering varieties, as distinguished from the October-flowering kinds you name, much more satisfactory, though the individual blossoms are not quite so fine. A few good ones are Lyon (rosy-purple), Anastasia (light-purple), Blushing Bride (rosy-lilac), Alice Butcher (reddish-orange), Précoce's (bright yellow), Crissun Précoce's, Tiberta, Flora, and L'Ami Condorhet (all shades of yellow), Piercey's Seedling (bronz-yellow), Martinnas (blush), P. Pâle (leucocrissun), Mme. Pécot (purple), and Mr. W. Piercey (bronz-red).—B. C. R.

GARDEN WORK.

Conservatory.

Now that the outdoor flowers are for the most part over, special pains should be taken to have the conservatory as gay as possible. It will, of course, be mostly understood that winter flowers cannot be improvised. A good winter display involves a long previous preparation. Even the Chrysanthemums, which are now so much in evidence, require some upon twelve months' work to bring them to perfection; and if they are to remain in good condition as long as possible, other things must in a general measure be subservient to them—at least, for the time being. Too much moisture or too much heat, and the flowers soon show decaying petals, and cleanliness and a freely-ventilated, dry atmosphere must be insisted on so long as the Chrysanthemums remain effective. Labor on when the forest flowers come in, the camellias can be altered to suit the plants which have been brought in to heat. To keep the flowers in good condition the house should never be altogether closed, except in frosty or windy weather. The watering now is a very important matter. Never neglect to immerse the plants. Plants, even when the pots are full of roots, dry slowly now, and though it will be necessary to look over the plants every morning, only a few may require watering. Unless there are visible signs of distress no plant should be watered without its condition being first ascertained by tapping the sides of the pot. To the practical ear the sound tells in a moment the condition of the mass of earth inside. Permanent plants with the roots in the border must not be permitted to get dry. Camellias, Acarias, and other plants in a free state of growth must have water enough. There is but a danger of these being overlooked, and they may grow the buds of the Camellias or the flowers of the Acarias, which in a hot house may burst in a week or more, some small. In a hot house the roots of the Acarias may be used to water the columns or to drain the walls. Give Camellias now opening their blossoms weak salt-water. This is best of their large smooth leaves, and if they are permitted to effect a blotch the plant is soon withered. I have had the Indian Daphnes very good planted in a bed of loam and peat well drained, and fragrant blossoms are always appreciated. Mignonette of the palm-growing variety when planted out becomes almost a shrub. I have seen denser bushes under glass which are always in flower, and will last two or more years; of course, with age the flowers become smaller and there is less fragrance, but young plants started early in spring, and planted in the nursery border about June, will make strong plants full of bloom in winter.

Stove.

Cypripediums are among the easiest Orchids to manage, and are also about the most useful, because they may when in blossom be removed to the conservatory or the room, and remain in flower for several weeks if watered carefully. There are many beautiful forms of these plants now, some of which are too expensive for the person with a slender purse to buy. Their requirements are plenty of drainage, some good fibrous peat and Sphagnum, with a free admixture of broken charcoal. The pots should be half-filled with drainage. During growth the plants require plenty of water, and to be syringed freely. After growth is finished root down, and give less water, but do not dry off altogether. Good plants of *C. insigne* for growing on may be purchased for a comparatively small sum, and *C. renatum* (barbatum), which will last for years, are cheap kinds; but a good trade list will contain something like one hundred and fifty species and varieties; so a good deal of money will be required to obtain a really good collection. The *Filtonias* and *Sonchidas* are very beautiful. The *Filtonias* when grown in pots are charming for table-decoration; but the *Sonchidas* are too delicate for rough work. They would be very interesting under a bell-glass in the small stove. The amateur might grow these who could not find room for larger specimens.

Cucumbers.

Seeds should be sown now for planting in a warm-house next month. Sow in single pots and plunge in a brick half-bush in a small frame or under a light. It is thought by some that old seeds are better than new; this is, I think, a mistake, for plants started now cannot have an excess of bloom. Plants raised now will be ready for setting out about the first of January, or perhaps a little earlier, and if pushed on freely fruit may be cut early in

March. Bottom-heat there must be of some kind; hot water is regular and steady; but where there are white pits and plenty of manure, the manure left in a narrow row will do quite well, so long as the soil is not too dry. At the top, at any rate, the plants like to rest in it, and it is a great help to them when they are bearing freely. There is nothing better for planting in than old, rotted turf, which has been laid up six months; this may be mixed with a little old manure. No great quantity is required to start the plants in, but as soon as they begin to grow, and the white roots work out on the surface, top-dressings of the same kind of compost must be given. During the early season care is necessary in the watering; and the water should be of the same temperature as the house. Always cut all Cucumbers when large enough for use.

Mushroom-house.

Do without fresh air as long as possible. Where new beds are frequently made up the heat arising therefrom will keep up the temperature; 55 degs. will be high enough to produce good Mushrooms. Fresh batches of Spakaly roots should be introduced every fortnight to keep up a regular supply. Blankets as often as is necessary; probably every three weeks will suffice. Put a few roots of Chicory, the blanched leaves will be useful for salads. Dandelion roots planted in boxes will be useful also for the same purpose.

Forcing-house.

Tea Roses which have been well ripened may be started now. Buds of many kinds which have filled the pots will grow as well in soil as in air, and will soon open its flowers in heat. Lilacs, Deutzas, Rhododendrons, Azaleas, Sissoons, the Red, Lily of the Valley, and any other forcing plants which have had a suitable preparation may soon be planted in heat.

Forcing Asparagus in Frames.

Asparagus will come on fast now in warm frames. Beds of sticks and straw, and leaves, 6 inches high will give heat enough to start Asparagus strongly. Mat up the frames until the beds are pushing through, then gradually expose to the light, and give a soaking of warm liquid manure. A little ventilation will help the favour. Asparagus frames will afterwards come in for Potatoes, Radishes, Carrots, &c.

Window Gardening.

Ventilate on fine dry days, but avoid cold draughts. The air should be admitted at the top, not the bottom. Water with judgment, and never leave any water in the saucers. Keep down insects on *Platygaster* by using the sponge dipped with soap and water; the flies may all be wiped off with a light brush. Begin in time, and the pests will not give much trouble.

Outdoor Garden.

Wesley lawn may be plowed now: the large weeds should be taken out, and a top-dressing applied to encourage the grasses to get strong and form a thick, close growth. Many lawns have been injured by drought during the past season. These are in the worst condition when the grass has been cut close to the ground. I may repeatedly urge in this column that the grass should not be sown down so close, till the machine is half an inch by dropping the front rollers; that half-inch of fibre over the roots will be a check upon burning in summer, and if well laid in the banishment of weeds and worms. Groups of *Yerbanensis* and *Tree Peonies* are charming things on the lawn; they are getting riper now, and when a strong roof of a good variety can be brought for a shilling, I think there is an extravagance in the purchase, having regard to their permanent character. French up the beds, but do not bring up hot soil. Add manure, and bury down its character. Leaf-mould may be largely used as a top-dressing for beds and borders, if it can be made at home. In country places leaves can often be had for the collecting, and when laid up for a year or a little longer they are very useful for mulching borders of bulbs, &c. Christmas trees are throwing up flowerings now. Though unexpanded at present there is but strong plants a promise of a good bloom. If possible, the blossoms should be sheltered with hand-lights, or something of a similar character.

Fruit Garden.

Those who are thinking of planting fruit on a large scale will find the advantage of getting the land into condition by breaking it up deeply either with the spade or the steam-cultivator, and during the winter have it well worked, and, if poor, manured, the cleaning and general preparatory work to be finished by pinning the ground with Pulverizer in March, or not later than the middle of April. If the steam-cultivator is used the crop of Potatoes will pay for the cleaning of the ground, and a heavy crop of fruit-trees may be planted with reasonable chance of success. I have seen several trunks of land treated in this way within the last year, and the result has been what one might expect from good work. Merely digging a hole and setting a tree in it is not planting it in the proper sense of the term, it is only just sticking it in. And even when larger holes are made and the trees are properly planted it does not give the tree so great a chance as when all the ground is thoroughly sanded up with a steam-cultivator 30 inches or so deep. Where not sanded are employed for producing the earliest lot of grapes they will now be in readiness for starting. It is not customary to repeat Vines just before starting, and, no doubt, there are good reasons for this, though I have several times shifted Vines on the eve of starting them I never found any bad results therefrom; but I think it is best if Vines are in pots too small to brush the top to wait till the trunks are set, and then repeat.

Vegetable Garden.

As regards sowing Peas and Beans in autumn, much depends upon situation and circumstances. In warm sheltered gardens it is advisable to sow towards the end of November in the warmest site available. If the garden is bleak and cold try and raise the first bit of Vias in pots or boxes, or in some other make-shift winter glass. In the early stages Peas may very well under glass in a temperature of 45 degs. to 50 degs., but they should be sanded when up more than 3 inches high. If kept in the pots too long the Peas may be weakly and tall over, the crop may be not worth much. Chichester, Gen. American, Wonder, and William I. are good early Peas. If sown direct open have the land in a good condition, and

before sowing, and cover about 2 inches or 2½ inches deep. If there is any danger of mice attacking them dress the Peas with red lead just previous to sowing, and either mice or rats will touch them. Kale are often damaged among Potatoes and other vegetables in this season. I have never found myself difficulty in clearing them off with phosphoric-gas sprays on Inval-sulphur and laid in their runs last thing at night. Must be taken up early in the morning and buried if it is not all consumed. Those who have plenty of leaves may make up hot-beds for Carrots, Early Potatoes, and any other crop of which early produce is required. It is perfectly true that all things move very slowly in winter, and if a start is delayed till Christmas is hurried not much time will be lost. E. Hooley.

Work in the Town Garden.

As Chrysanthemums go out of bloom they should be cut down to 6 inches or 8 inches of stem, and such as are required to furnish cuttings for next season's display be removed, if possible, to a root and low pit or frame. Any surplus may be thrown away at once. In such a position as I have just described, and where plenty of air can be given in mild weather, and the plants stand close to the glass, they produce far stronger and better cuttings than if standing far from the glass, and perhaps shaded by other plants, and in an unnecessarily high temperature. They will stand in pots close to the glass, but save old stocks thrown over the glass will effect this at least, in the present; but bear in mind that if once thoroughly frozen through the pots very few of the modern show varieties will survive. Where a few extra large specimen plants are desired it is a good plan to reserve a few plants of such free-flowering varieties as Klaine, any of the *Itulle* family, Fair Maid of Hamsey, Mme. Louise Leroy, or almost any of the reflexed class, choosing such as show signs of breaking freely from the stems. Do not cut these down quite so low as the others, remove all suckers, keep them in good greenhouses temperature, and spray them occasionally overhead, and if stopped two or three times and shifted on into large pots during spring and early summer such plants will attain a very large size, and produce an immense number of moderate-sized but most useful blossoms. Begin striking cuttings of such varieties as Bonté d'Or, R. Brocklebank, Meg Merrilies, Coronet, and other varieties that require a long season of growth. The cuttings strike better in an ordinary greenhouse temperature of 45 degs. to 50 degs. than in either a cooler or warmer place; but to prevent flagging they should be placed in a rough kind of frame, and not too closely covered with an old sack, or with a few horse sheets of glass until rooted. The removal of some of the early Chrysanthemums from the greenhouse will allow the stock of other plants to be spread out considerably. Chinese Primulas, single and double, will be in full beauty now, and should constitute quite a feature, as they are decidedly the best winter-flowering plants for a town garden we possess. They succeed best at this season on shelves moderately near the glass, and to keep them in full vigour the soil must ever be allowed to grow in the ordinary way. Examine the earliest potted batch of bulbs, and if the pots are full of roots and the tops show signs of moving, clean over a few of the most forward pots of *Rumex*, *Fraenula*, *Van Thol*, *Tulips*, *Paper-white* and other Narcissus, and subject them to a moderate amount of 60 degs. or so, when they will be well on by Christmas. Bulbs of the Valley require a stronger heat at this season, and of these no result may be looked for yet. *Bonnyas* are very beautiful now in a warm house. H. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from November 25th to December 2nd.

Baked up and watered leaves for making hot-beds, &c. A large quantity of manure are annually used for making hot-beds, consisting of vegetable refuse, which decayed at the end of a year or so make excellent compost, suitable for many purposes. At the present time I am using the compost from the old hot-beds for top-dressing and mulching Lilacs and other bulbs in herbaceous borders and elsewhere. Beds of Lily of the Valley and Christmas Roses are annually mulched with the old hot-beds, which are largely composed of tree-leaves. Made alterations in several parts of the grounds, including the opening up of a shrubbery by the removal of some old Laurels, Lilacs, &c., and the planting of a group of four of *Laburnum* and *Prunella*, consisting of green and variegated varieties, are also partial to the introduction of *Burford* Laurels. They give a hint of green different to most evergreens, and which allowed to grow out form grand masses of foliage, and large plants flower very freely. In a suitable position, put out upon the turf, three plants of the Venetian *Sunshades* have been planted with the view of their forming a group of larger size than could be obtained from one plant. Another plant which is pretty for grouping, especially in the margin of the turf, or even altogether on it, is the *Tamarisk*, commonly used for wind-breaking. It is sometimes wears a rusty tinge when the leaves are dying, it is a charming thing in summer, and is very light and elegant framed over a building. Though mostly considered a low-growing shrub, it will cover a wall 20 feet high in a reasonable time. Having much faith in the capabilities of Lamb's Prince Albert Apple, a considerable number have recently been planted. It is a good cropper, and comes into bearing early. No one can possibly do wrong in planting several trees either on the Crat or the Broad-green, and even a small tree from one of the old trees kept out, but all favourable occasions for light are drawn off, so that the plants for some hours at a time may have full exposure. This helps the foliage and enables them to bear up under the close covering which will have to be given to many things should severe weather set in. There is no letter coming than dry Bracken, and if this is cut in summer and stacked it will be ready for use. Bracken cannot be had everywhere, and in such cases one might find bark upon dry straw, which might be used as thick, laid upon wooden frames and secured with tar, or by other means, covered with straw, and some may use mud (Buckingham) or Bayley-straw for covering livers and other vegetables. They are cheap and fairly durable. When one has a good supply of Bracken, I like these even better than

straw. It is often a question of cost, the cheapest material having the preference. Covered Fig-trees on walls. Unlike most other fruit-trees, covering does not seem to have any ill-effect upon Figs, and if the roots are now in a good condition a crop is certain.

ROSES.

ROSE NOTES.

I HAVE been requested to name Roses suitable for various purposes so often during the present planting season, that the following notes may be of some service to many intending inquirers:—

ROSES FOR A WARM POSITION OR A SOUTH ASPECT.—Climbers: White and Yellow Bank-sims, the Austrian and Persian Briers, Fortune's Yellow, William Allen Richardson, Lamarque, Triomphe de Rennes, Céline Forestier, Sulfaterre, Cloth of Gold, Maréchal Niel, Climbing Niphetos, Climbing Devonianais, Madame Eugène Verdier, and Belle Lyonnaise. Dwarf growers: Comtesse de Natchille, Comtesse de Parisse, Niphetos, Souvenir d'Elise Varlot, Catherine Bernet, The Bride, Madame Polot, Rubens, Perle des Jardins, Marie Van Houtte, and Innocente Pirola (here figured).

FOR A MORE EXPOSED SITUATION the following climbers may be used, while, of course, the same

little value unless used to supply flowers a considerable time before the earliest varieties open upon walls outside; and they also need the slight protection of a pit or frame from the early part of November. This induces sap to rise and new roots to commence. Now, if the pruning is delayed too long the wounds "bleed"—i.e., exude sap—and not only do we lose a considerable amount of strength, but the points of young roots are also affected; they stop growth, simply because a severe check has been given to the rising sap. My readers will see what I mean more plainly if they will turn out a plant which has had a check from severe and late pruning; the points of roots turn brown, and often die. But when the pruning is done early we secure the full benefit from root growth, and all of its energies are devoted to the eyes remaining upon the plants. There is a great difference between early pruning of pot Roses and those in the open border. The former are pegged early, and can be protected from the injurious checks caused by late frosts, which the latter are often unmercifully subject to. An unchecked growth should be aimed at; even the latest batches of pot Roses will be much better if pruned now, because they will be stemily preparing themselves for quick growth when introduced to heat.

only they will not reach the same height as the others. Provide a good soil 18 inches deep for your Roses if you can, and set out own-root plants, and you will never regret it.—J. C. C.

4944.—**A bushy Ross, &c.**—I am afraid the aspect you describe will be against any Rose thriving with much satisfaction. You might try Gloire de Dijon for one, but this is not lushy, and would require a little pruning to keep it within the required bounds. The Japanese Roses are exceptionally hardy, but have only single flowers. However, they are produced in abundance, and are followed by very showy berries. Stanwell Perpetual is another variety which might answer your purpose, so might the strongest of the Scotch Roses; but you are not giving good Roses much chance in the position you mention.—P. U.

LIQUID-MANURE AND ITS ABUSE.

In the cultivation of plants and flowers liquid-mannure forms an inconsiderable element towards success or failure. No hard and fast rule can be laid down, but the application of this stimulant is of so much importance that I propose noting a few of its benefits and abuses. First of all, I would warn against the regular use of solutions of definite strength. Like the foolish plan of watering by rote, such as daily, bi-weekly, &c., one then either gives water when not needed, or else affords a much less supply than the plant requires. A hot day, or a cold, drying wind, will have considerable influence upon all plant life, and during such a time double and treble the amount of moisture is needed in comparison to a dull or wet period. If we water by rote, the two extremes so often fatal to plant life are reached. If of so much importance to apply ordinary water with this care, it becomes much more so when dealing with liquid-mannures. There are two points which should never be lost sight of—viz., not to give stimulants except when the plants are in full growth, and the soil in a semi-moist condition. Unless the roots of a plant are in such a state as to be able to assimilate this form of food quickly it has an injurious instead of beneficial effect. From this we can readily imagine the folly of applying liquid-mannure to weakly plants; and yet this is frequently done with the object of bringing them into full growth and health. Another grave error lies in affording solutions of too strong a nature; for better apply the same strength in two or more doses. Nor should a plant which has recently been fresh potted ever be watered with liquid-mannure. Until the food contained in the new soil has been almost exhausted, and the whole well permeated with fresh roots, such applications will only tend to make the compost stale and distasteful, instead of aiding the plant. A pot-bound plant, in growth, derives great aid and benefit from liquid-mannures of a rather weaker character than the amateur usually applies. The exact strength depends so much upon the class of manure used, as well as the subject treated, that no guide can be given in a general article of this description. For example, Arum Lilies and Cinerarias will benefit from much stronger and more frequent doses than would be safe or necessary for such slow-growing plants as Azaleas, Camellias, Palms, &c. We also find that many plants are much more partial to one kind of manure than another, but if a little care be taken in applying them weak, and when the roots are in a proper condition, almost all liquid-mannures are beneficial. There must be the necessity for extra food—viz., healthy growth, with its attendant hungry roots, otherwise this form of stimulant is decidedly injurious.

P. U.

Rose "Innocente Pirola."

will also do well in a warmer position: Aimé Vibert, Miss Glegg, Gloire de Dijon, Rêve d'Or, Madame Bernet, Henriette de Beauveau, Emile Dupuy, Kaiserin Friedrich, L'Éclat, Madame Chancery, Chesnut Hybrid, Reine M, Henriette, Waltham Climber No. 3, Fulgenscent Blanc No. 2. Dwarf: Anna Olivier, Marie Van Houtte, Homère, Madame Lambert, Dr. Grill, Souvenir de la Mulmaison, the Rugosa or Japanese Roses, the White (B. Moreau) and crested Mosses, the Old Cabbage, Common China, Bardon Job, Augustine Guinnoisseau, Souvenir d'un Ami, Madame Casin, Edith Gifford, and Ernest Metz. In addition to these we may name the following to be dark-coloured Hybrid Perpetuals as suitable for rather exposed places: General Jacqueminot, Abel Carrière, Countess of Oxford, Annie Wood, Dupuy Jamain, Duke of Edinburgh, Eugène Pêrce, Fisher Holmes, Prince C. de Rohan, Charles Lefebvre, Suzanne Marie Rodocanachi, and Ulrich Brunner. A dozen hardy, light-coloured Perpetuals will be found in Mrs. John Laing, Boule de Neige, Business Rothschild, Elie Morel, Mercedes de Lyon, Marguerite de St. Amand, Madame Montet, Madame G. Luizet, Jeanne Dickson, Heinrich Schmittheis, Anna de Diesbach, and Her Majesty.

POT ROSES.—During the latter part of November it is a good plan to prune all pot Roses. When left later than this they are apt to take a considerable amount of

4941.—**Roses for pegging down.**—"Rugosa" will get the best effect for a short time by using strong growers and pegging them down; but for a more constant supply of flowers I would strongly advise dwarfs of a more lushy habit being planted. Gabrielle Luizet and Gloire Lyonnaise, &c., give a fine bit of bloom once in the season, but seldom produce more than a solitary bloom or two during the remainder. General Jacqueminot, La France, Anna Olivier, Augustine Guinnoisseau and others of like character produce successional crops all through the summer and autumn. Plant the latter kinds about three feet apart each way; and those intended for pegging down, six feet apart. The latter produce long growths, and you need more space for them. In pegging down do not scruple to cross the shoots over one another if necessary to cover the ground; it will not be seen when foliage appears, and as they are cut away later on there is no harm done.—P. U.

Plant the plants 2 feet apart all round the bed, and 18 inches from the outside; then fill up the remaining space with the plants 2 feet 6 inches apart each way. This distance is, I may say, given for an ordinary soil, but 6 inches more may be safely given in what I may call a good Rose soil. If you are looking for effect, icky, a bed of dwarf plants will be the best. You will, however, get about three times the number of flowers from pegged-down growths.

4857.—**Destroying ants.**—You should endeavour to discover the nest—not a difficult matter—and over it place an inverted flower-pot. The ants will work into this pot, and then with a spade one can remove the whole affair and plunge into a pail of boiling water. Dressing the place with sulphur is sometimes efficacious, or laying about bits of sponge soaked with sugar. They soon find them out, having a strong liking for sweet things. This is the usual way of dealing with them in plant-houses.—C. T.

Fill a saucer one-quarter full of sweet oil, and place it near their hole. The ants will get into the oil, and not be able to get out again. J. C. C.

SOME GOOD HARDY LILIES.

It is advisable now that the hardiest Lilies should be planted at once in their permanent out-door quarters, and it is also a good time to buy them at a moderate expense, as many varieties reach this country in November from our principal Lily exporters, the Japanese. It seems wonderful to those who recollect how comparatively recently the L. auratum was first introduced into this country, to find them sold in hundreds and thousands of prices within the reach of everyone—even the humblest cottager. From my own experience of this very handsome Lily I should not care to recommend growing it extensively unless the person planting the bulbs be prepared in a few years, and quite likely in a shorter time, to find them becoming small by degrees and beautifully less, and then disappearing. The only reliable exception to this general deterioration of the auratum family is mainly confined to the varieties platyphyllum and merranthum. I do not know the exact difference between these varieties; I have bought them under both names, but they seem similar and are also satisfactory. Those I have longest in my possession, for some six years, and which never have deteriorated, I believe to be platyphyllum. To people to whom expense is no object I also recommend growing the variety virginale and the red-banded L. a. rabro-vittatum. Virginalis is a beautiful Lily, having a pale gold band and no spots; it is well named. Besides the auratum and its varieties, there are many other Lilies which grow well out-of-doors. To every one, L. candidum, the Madonna Lily, and L. croceum (the Orange Lily) are known, but every one cannot grow them successfully, as L. candidum especially is most tantalising, growing freely and well in the gardens of cottagers, but with every apparent advantage doing very indifferently in many good gardens. I do not think that even experts have accounted satisfactorily for these vagaries; at all events, I have read numerous reasons and remedies given, and have tried the latter when mine have done badly, but cannot say with very good results. It grows where it likes. Lilium chaldeanum is one of our best known varieties, having been grown in this country for centuries, but it is not very frequently seen. Why this is I cannot understand, but it may be in part accounted for in the fact that it is not imported largely, as many other Lilies are. It is a very remarkable kind, its scarlet reflexed flowers showing most prominently amongst other flowers. I believe this Lily comes from the Grecian Archipelago, and its oriental magnificence of coloring is quite in keeping with

one for the other, but when testaceum arrives at the bud stage, and subsequently in blossom, there is a decided difference; the flower of testaceum when fully open is curled back somewhat like others of the Turk's-cap or Martagon varieties, to which group this Lily belongs. Testaceum and candidum flower about the same time. L. Humboldti is a fairly hardy grower, but I have found it requires a second year in the ground before it grows or flowers properly. It is of an orange colour, with black spots. Of the earliest Lilies I think the L. Kramerii to be the loveliest of all as regards its delicate colouring, and it has a most agreeable scent, but it is somewhat delicate, and very difficult to grow in or out-of-doors. Taking this latter fact into consideration, as also its price, as compared with the size and growth of the bulb, I can hardly commend it for general or popular cultivation. I do not believe, with every advantage of skill and careful cultivation, you can command success with this Lily. At one time I thought I had found out the secret, having been very successful, growing them with as many as seven flowers on a stem, the more usual number being from one to three or four; but out of some 150 bulbs I once possessed I have hardly six left, the reason for my loss being quite incomprehensible to me. Comment on any possible remedy is almost unnecessary. I may say, however, that I envy those who can grow L. Kramerii with anything like success, as there is a delicate refinement about it which few Lilies possess, the beauty of Lilies being more usually of a very pronounced type. L. Browni (see illustration) and its almost identical variety Colchesteri are worth growing for their remarkable size and distinctive colour—creamy-yellow inside the trumpet and a brown tinge outside. They are handsome and effective in the Lily garden and not objectionable indoors, the scent being agreeable and not overpowering. It is an expensive bulb, but I think worth having and necessary in a good collection. Of the longiflorum species—one of our oldest kinds, having been imported about 1820—the original type and Lilium Harrisii are probably the best. In Bermuda these Lilies are grown by the hundred thousand. The Americans are great admirers of the Bermuda Lily. It is very effective in pots, and when you can grow longiflorum successfully out-of-doors it is a very desirable acquisition in the garden. I have found one rather common defect in the flower—the trumpet frequently, when developed, splits, and is of little use then for specimen table decoration, although, no doubt, it can be otherwise used effectively where faultless growth is not an absolute necessity. Of the later varieties, those which are most generally useful are L. tigrinum splendens, L. speciosum rubrum (variety Melpomene), and L. speciosum album (variety Kratzeri). These three kinds of Lily, if planted in a fairly suitable position, will bloom till October, and Kratzeri until late in October. I have quite recently (this being November 7th) cut a large number of flowering-stems of L. speciosum Kratzeri, but have had to open most of the buds indoors. As they were planted in a somewhat shaded position in a clump of some 150 Lilies near my house they were unable to properly develop their flowers from want of morning sunshine and after the recent cold and frost, but in a sunny position they will properly develop and be satisfactory all the late autumn. These are but a few of the best Lilies which can be grown in most cases with the greatest ease and with marked success in the open. Remember to plant now before severe frosts overtake us. C.

THE KITCHEN GARDEN.

CUCUMBER "BONNEUIL LARGE WHITE."

In reply to "J. R.," "D. B.," and others, this Cucumber, which is almost always grown in the open air in France, is quite distinct from all other varieties. The fruit, instead of being almost regularly cylindrical, is ovoid in shape, swollen about the middle, and, moreover, very perceptibly flattened from end to end in three or four places, producing the same number of angles more or

Cucumber "Bonneuil Large White."

less rounded. It is very large, readily attaining the weight of 4½ pounds. Like the fruit of the Early White Cucumber, it is at first of a pale-green colour, and whitens gradually as it increases in size. This is the Cucumber which is most generally grown about Paris for the perfumers, who use large quantities of it in their manufactures.

4882.—Treatment of Rhubarb.—Rhubarb will grow under very rough treatment, either in good ground or bad, and even on the surface of the ground. But to cultivate it properly is in the following manner: The situation is not of very great consequence; still, if wanted early, a south or south-east border will be best. The ground should be dug to the depth of 18 inches or 2 feet, as much half rotten manure dug in the trench as the quality of the land may require; but you cannot very well overdo it, as this plant is a gross feeder. When thus prepared the roots can be planted about 3 feet or 4 feet apart every way. The present time is a very good time to make the plantation. But "M. C." has, I presume, an old bed of Rhubarb that he wishes to improve without moving the plants; if so, proceed in the following way: Dig out the soil between the roots, placing it on one side. Do not dig too near the roots to damage them too much, though they are not easily injured in this way. Fill up with rotten stable-manure, placing it well round the roots. Fill in soil, make all smooth, and proceed in the same way until finished. Then place a forkful of longer manure over each crown to preserve from frost. Though this plant is thoroughly hardy, still, I think a little protection in this way is useful, as it protects the young growth in the early spring.—J. BRYES, Rugby.

4843.—Onions for show.—Referring to "Lerner's" query in GARDENING, Nov. 4, it may be interesting to him and other amateurs to know how Onions are grown for show in this quarter. I sowed the seed in a hot-bed about the middle of January, and when the plants are 3 inches long I prick them off into 3-inch pots; grow them on in a temperature of about 60 degs. till the middle of March; then repot into 4½ pots, using good loam, leaf-mould, and sand, in about equal parts; place one crock in the bottom of each pot; fill the pot about one-fourth full of well-decomposed old stable-manure; remove the Onion from the 3-inch pot, and, without breaking the ball, place it in the centre of the 4½ one, potting rather firmly; grow the plants on in heat till the beginning of April;

Flowers of Lilium Browni.

the surroundings of its native habitat. One of the hardiest as also one of the hardiest of Lilies is L. Szovitzianum, but it has a vile scent, and is, therefore, only hearable in the open. It is, however, exceedingly effective, and is an early variety; therefore, well worth cultivating. L. testaceum or excelsum is a strong and easily-grown variety. Its colour is very distinct, being, in fact, exactly what is named by some cultivators.

THE NANKERS LILY, which is a sort of light-yellow. The growth of testaceum is very similar to that of candidum, and these Lilies might easily be mistaken for the foliage and the

4904.—Double and Single Violets.—In a case like this prevention is better than cure—if the plants had been kept properly watered during the dry weather they would be free from insects now. I do not see that you can do more than syringe the under-sides of the leaves twice or three with some good insecticide, and keep the plants well supplied with water and weak liquid-manure. Yes; the double varieties seem to appreciate a very gentle artificial warmth or bottom-heat during the winter.—B. C. B.

4903.—A garden hedge.—Sunflowers, Hollyhocks, Dahlias, Delphiniums, Boccunia cordata, and Polygounum are good. Some or all of the above may be planted in a row, and the Laurel-hedge got up, &c.

then harrow off, and plant out towards the end of the month. Prepare the bed you intend growing them in now by giving a good coat of manure, digging it in deeply; some warm lime may be given with advantage. Raise the bed 4 inches or 5 inches above the ground level, so as to keep it dry, for Onions are difficult to ripen sometimes in wet seasons. All through the season they will require attention as to watering with manure-water once a week, but this must be stopped when the first signs are seen of the top of the leaf blades are turning yellow, for they are then beginning to ripen, and if a second growth is started they will nearly all split, and grow on till winter. If they are to be exhibited dried you must lift them three weeks before the show, but if shown as grown they may be lifted on the show day. Cranston's Excelsior is the best of all the large show varieties. Ailsa Craig is also good, but is more apt to shunt. By this mode of culture I grow them 18 inches in circumference, and 2 lb. in weight each.—W. H. P., *Ayrshire*.

FORCING ASPARAGUS.

Throughout the winter months Asparagus is looked upon as a luxury amongst vegetables, and where a supply of this can be maintained in conjunction with other choice vegetables, the grower has little to fear as regards the supply of winter vegetables being appreciated. Rarely, however, is this the case, as a sufficiency of Asparagus roots suitable for forcing throughout the winter is more the exception than the rule. Some soils are naturally adapted to the growth of Asparagus, being of a well-drained, sandy, or gravelly description, a heavy manuring previous to sowing and planting, and a top-dressing of the same annually being all that is needed to bring the crowns to a condition suitable for forcing. It takes from three to four years to secure roots strong enough for forcing, and if more time was allowed it would be all the better. Sometimes I have forced younger roots, but these had been grown well on good soil. The reason, I believe, why this method of securing good roots of Asparagus for forcing is not generally carried out is the old-fashioned belief that expensive preparations are needed, such as raised beds and so forth. This is a very erroneous opinion, as good roots suitable for forcing may be produced with no more trouble than is bestowed upon Potatoes. Some people break up an old bed annually and prepare a new one, but this, I think, is not a very economic method. On heavy, wet land a raised bed would have to be made if the roots are to thrive as they should do, but on light land this is quite unnecessary.

Asparagus roots may be either forced on hot-beds or by the aid of hot water, or the two combined. Where forcing has to take place entirely on hot-beds, a well-made hot-bed is of the first importance, as a steady and lasting heat is what is necessary. At this season of the year tree-leaves are abundant, and these, mixed with the same bulk of stable-litter and formed into a bed, will retain the heat much better than when only manure is used. A bed at the least 4 feet in depth should be formed quite 6 inches larger all round than the frame when placed in position, so that a lining may be given to keep up the temperature. After being made up and any violent heat expended, a layer of light soil should be first placed over the manure, afterwards packing in the roots closely together. A covering of light soil sufficient to cover the crowns to the depth of 2 inches must also be put on. To think that a heavy dressing of soil is needed to cause blanching is an erroneous opinion. If blanched produce is needed, cover up the top of the frame so as to exclude light. I think blanching is quite an unnecessary proceeding, but if so desired it must be done. After the roots are packed in, a good watering with tepid water will be all that is necessary. A little ventilation at the back of the frame will be needed on all favourable occasions, and the frames should be closely matted up during frosty nights.

HEATED PITS where the body of the pit can be filled up with fermenting material are the most suitable. Many such pits are used for growing Cucumbers and Melons during the summer months. Such pits generally allow of a depth of 2 feet of well-worked fermenting material being placed firmly in the bottom. Even where

bottom-heat pipes are provided, it is better for the well-being of the roots to have a layer of litter spread over the brick rubble which is generally placed in heated pits where the bottom-heat is derived from hot water. In these heated pits a top temperature of 55 degs. to 60 degs. is ample, with a bottom-heat of 80 degs. A succession of roots put in about every three weeks would keep up the demand.

THE TURN OF THE YEAR, or from about the middle of February, forcing permanent beds has much to recommend it. This is by no means a new system, as I remember it being done quite twenty years ago by the late Mr. James when at Reildes, Isleworth. Each bed is 4 feet in width, with an alley between of 3 feet or 4 feet in depth and the same in width, the sides being bricked up and pigeon-holed. This space is for the reception of fermenting material, the top of the bed being covered with a length of low span-lights. The heat from the fermenting material raises the temperature of the bed and growth soon takes place, the lights being further covered with mats or litter at night, so as to assist in the retention of the heat. Where blanched produce is needed, the beds are kept closely covered up. A 3-inch flow pipe all around the bed also assists in keeping up the heat. It does not do to force these permanent beds too hard, or there would be danger of their being worn out. By careful forcing the beds will remain productive for

early Tomatoes for market on a small scale does not pay. If you can grow them in sufficient quantities that you can choose your own market you may do much better. Growers and the retailer in the neighbourhood in which I write all say that there is but a limited demand for ripe Tomatoes in or near a small country town until the price comes down to about 8d. per lb. At that price they do not pay for very much fire-heat, as at best it will take between four and five months to get ripe fruit, reckoning from the first of January. I find the beginning of the new year quite soon enough to sow the seed; even then the progress must be slow or the plants will be badly drawn up.—J. C. C.

Seeds may be sown now for the earliest crop. A good selection of the Old Red takes a good deal of heating for the first crop. Some of the strains of Old Red produce nearly smooth fruit, and these cannot be improved upon for early work. Later on might come in Ham Green and Perfection. Carter's Market Favourite when true is a good variety.—E. H.

4910.—**Spring Onions.**—Celery forms a much better preparation for Onions than Carrick. To grow good Onions liberal treatment is necessary. With me the ground receives a heavy manuring as the land is being trenched in winter, and in February a further dressing of short manure is given, and just lightly turned in.—E. H.

HOUSE & WINDOW GARDENING.

HYACINTHS IN GLASSES.

This is an old-fashioned way of growing and flowering Hyacinths, but it is not nearly so much followed as it used to be, and yet it is a

Hyacinths in glasses.

many years, the aim being to encourage a strong early growth by surface feeding and the application of liquid-manure. If it could be managed, a portion should be forced in alternate seasons. As the season advances little forcing is needed, the pits being filled up with leaves and the beds covered with a span-frame, so as to ensure the natural warmth, and as a protection from late frosts.

4949.—**A kitchen garden near a river.**—As the soil is sandy I did not anticipate that you will meet with any serious difficulty in growing Plum-trees on the wall fence, but I do not feel so confident about Pears. The common Green Gage, Gishorn's Page, Angell's Bartlett, Cox's Golden Drop, and Victoria are the sorts I should select, and this number will be sufficient to fill up the space. It would be a good plan if you could raise the border 18 inches high at the back; but to do this you would require a stone or brick wall that height above the present level for the board fence to rest on. I do not think you can do anything better than this to keep the roots out of the damp soil below; creating the bottom to keep the roots from going down is not a very expensive job, but too much so, I think, to be worth it. You may safely plant the trees up to the middle of March. I advise you, however, to order them at once for delivery at the proper time.—J. C. C.

Early Tomatoes for market. From my experience I should say that growing

very pleasant method. I have known very fine flowers produced in this way; but it is mainly a matter of attention. Neglect Hyacinths, and failure is certain. I have seen the bulbs started into growth in glasses, and grown on for a time until they had put forth good roots, and began to make an upward growth; then they were brought out of the cupboard and placed in a living-room, only to be neglected. Supposing the Hyacinth bulbs were put into glasses at the end of October or the beginning of November, and placed in a cool, dry closet or cellar, where they have been excluded from the light; they will by this time have put forth good roots, and partly filled the glasses with them. When brought out into the light the glasses should be examined to see if the water wants renewing, and if so, it should be emptied from the glass, which, together with the roots, should be well washed to thoroughly cleanse them from any impurities. Then put them back again and refill the glass with clear fresh water. I have always adopted the practice of putting some small pieces of charcoal into each glass, which help to keep the water sweet. The glasses may now have the full benefit of the light from a window, but on no account should they be left in the window on a frosty night if there is danger of the water becoming frozen. It is always safest to move the glasses back on to a sideboard or mantelpiece by night, replacing them in the window by day. The golden-shaped glass with a broad, flat, circular bottom is the best for growing Hyacinths. This cannot topple

over, as was the fashion with the oil, tull, upright, chimney-shaped glass. Neat supports are sold with the glasses, by which means the inflorescence can always be kept in position. These glasses can be purchased cheaply in handsome patterns, and they are very useful in the summer and autumn months for cut flowers. Prizes used to be offered for Hyacinths grown in water, but it was seldom the real thing was obtained. The exhibitors almost invariably grew and flowered their Hyacinths in pots, and then shook them out of the soil, washed the roots clean, and placed them in the glasses a week or so before the date of the exhibition. R.

GOOD ROOM PLANTS FOR WINTER.

AMATEURS are always inquiring the names of a few good room and window plants, particularly for the winter, when flowering ones from a greenhouse seem to quickly fade. One reason of so many failures is that they are bought from barrows, and these plants are forced in heat to make them sell. They look in the perfection of health, but, so to say, possess no stamina, and the change from the hot-house to the dwelling-room is too great.

THE PARLOR PALM (*Aspidistra ltrida variegata*) is one of the best of all room plants, and stands first in my selection of the best twelve. The reason is that the leaves are leathery, and practically impervious to dust, hence the reason why those trees and shrubs with thick foliage succeed so well in towns and suburbs. Soft-leaved things get covered with soot, and Conifers, for instance, get choked to death. The *Aspidistras* is rather expensive, the plants being valued by the number of their leaves, each at 1s. Of course, after a certain number that is not so, but this is the usual way to price young plants; and the more distinct the variegation, so much the more the expense. The flowers are very curious, not attractive, and produced on the surface of the soil. Loam mixed with peat is a good soil, and provide a good drainage. After potting stand the plants in the greenhouse if possible to assist them to become more quickly established. A great fault with amateurs—or gardeners generally, for that matter—is constantly repotting their plants, which is not required. As a rule, in the case of such things as these, the less they are disturbed at the roots the better. A great check is imposed by this constant disturbance, and they never increase properly. As so frequently pointed out in GARDENING, it is essential to sponge the leaves frequently with tepid water to remove dust and dirt from the surface. Once a week at least this should be done.

INDIA-RUBBER PLANT (*Ficus elastica*), is the next best room plant for winter. It is not so useful nor so vigorous as the *Aspidistra*, as there is a certain objectionable stiffness about it, but it often thrives where it is impossible to grow flowers. A good loam and peat-soil and a moderate amount of drainage must be given. But the most important thing, as in the case of the *Aspidistra*, is to sponge the leaves at frequent intervals to remove dust and dirt. When the foliage begins to turn yellow a little soot-water will be beneficial, but there is really little attention required, simply not to overpot or repot too often, and water very carefully during the winter months.

THE OPHIOPOGON is another good window or room plant, although usually kept in a greenhouse or conservatory. But it may be brought into the room, and its wealth of narrow green and creamy-white variegated leafage is very attractive, especially when set off by spikes of sapphire-blue flowers. It grows freely in an ordinary sunny soil, and when used in the greenhouse is very pleasing in a terra-cotta vase or window-box, so to say, on a greenhouse shelf.

THREE EXCELLENT FERNS for rooms are *Pteris cretica*, its variety *albo-livata*, and *P. tremula*. I do not think it is possible to get a more useful trio, all being so vigorous, and not like the majority of Ferns, averse to cultivation in rooms. They succeed in ordinary peaty soil, and greatly dislike an oversupply of water.

DRACENA INDIVISA is another useful plant hard to kill, and always fresh in aspect when the foliage is kept properly sponged, and to this small selection may be added the *Date Palm*, *Corypha australis*, *Crotonia robusta*, the Norfolk

Island Pine (*Araucaria excelsa*), very pretty when small and distinct in aspect, and the Sedge (*Cyperus alternifolius*) and its variegated variety, which requires more moisture than any of the other plants mentioned. It is graceful, free-growing, and pretty when stood on a small table so that its fanciful growth is in no way cramped. All the foregoing kinds I have grown for years in rooms, and during the winter especially they succeed better than anything else I have tried. F. P.

CAMPANULAS AS WINDOW PLANTS.

THESE will thrive well in pots and baskets, and make most excellent window plants. I saw during the past summer in some villages near the Norfolk coast most delightful groups of

Flowers of the White Peach-leaved Bell-Flower (*Campanula persicifolia alba*).

Campanulas flowering in great profusion in cottage and other windows. A notable kind was the one here figured, *C. persicifolia alba* and the type, and also *C. garganica*, *C. Barrolieri*, *C. isophylla alba*, and *C. fragilis*, extremely beautiful for a suspended basket. Those who have not tried *Campanulas* as window plants in pots and baskets should do so. The plants should be potted up early in spring. H. B.

FILLING WINDOW-BOXES.

DURING winter window-boxes may be made to play a much more important part in the decoration of the house than in summer, for the general bareness of the outlook makes the window-box then come out much more prominently. After trying all sorts of things, I am inclined to say that in our variable climate flowers are impossible if fully exposed to alternate freezing, thawing, and drenching with rain. Far better fill the boxes with really hardy foliage plants and shrubs, which will vary considerably in different localities. Here, by the seaside, there is nothing so effective as nice lush little plants of golden-leaved *Eonymus*, alternated with the dark-green form, or *Laurus tinus*, *Box*, or *Aucuba*, the soil being covered with *Stonerop* and bulbs of *Crocuses*, *Snowdrops*, or *Hyacinths*, placed in front of the shrubs to add colour in the spring. For variety, boxes may be filled with *Wallflowers*, *Veronicas*, *Forget-me-nots*, and *Pansies*, with bulbs in the foreground, and these will be very gay in spring, but are not so bright in winter; or bulbs alone may be used with excellent effect in spring, but are bare during mid-winter. I lately saw some boxes with the surface of soil covered with the freshest green turf, and under this bulbs were planted for spring display; in fact, window-boxes admit of a great variety of subjects being brought close under the eye of the owner. J. C., *Hants*.

Leaf-mould.—Queries respecting this valuable compost and its manufacture are frequently appearing in GARDENING, so that as the present is a most favourable time for its manufacture, I propose giving a few hints upon the process. Almost any tree-leaf will do, but those of the Oak and Beech are preferable. Quantities of these may be collected from the ditches and roadsides. If a little good loam can be obtained

and mixed among the leaves, so much the better. Another splendid mixture is road-scrappings, this often containing much horse manure as well as grit. Vegetable refuse, weeds, &c., may be kept separate if desired, but my own plan is to intermix all such things with a large quantity of leaves and road-sidings. If the whole be turned over occasionally, decomposition will be accelerated, while a little fresh lime, besides helping in this connection, also keeps the whole sweet, clean, and free from insect pests. In decayed vegetation we get plant food in the most perfect state for easy assimilation, and very few subjects can be grown in better or more suitable compost than the results of what I have briefly described.—P. U.

ORCHIDS.

ANSELLIA AFRICANA.

I AM in receipt of a nice truss of flowers from "Lincolnshire" of this fine old plant, and I am not surprised at the high terms in which it is spoken of, for I consider it one of the most beautiful Orchids for flowering at this season of the year. It also speaks well for the warmer kinds of Orchids, because the heat that is required to grow and to bloom this Orchid, is sufficient to grow nearly all the East Indian kinds. This plant was brought home to us here between fifty and sixty years ago, having been found in Fernando Po, in West Africa, and Dr. Lindley named it after its discoverer, Mr. Ansell, who was attached as botanist to the Niger Expedition, since which time, however, it has been found in various parts of the West African coast, and, indeed, I saw a nice dwarf kind having larger flowers than the type with Mr. Bull, of Chelsea, about two years ago flowering in the summer months, and although the plant did not look quite so gay then as it does at this season of the year, it was a very acceptable change. I do not know whether the plant was flowering at its normal season or if it should have bloomed more in accordance with the species which I now have under consideration. I am much obliged to the sender of this fine truss of bloom; it makes a grand ornament placed in water, and by cutting about an inch or a couple of inches off the stem every two or three days and renewing the water, it will continue to enliven my room for a long time; but I would remind the sender that although I heartily rejoice at his gift, I do not wish so to rob him of the beauties of his houses, and the little spray from the base of the spike bearing five flowers would have been ample for me to have determined the species, as well, indeed, as a large spike bearing thirty flowers which were well packed, not one of them being either bruised or injured in any way. This gentleman tells me that "he has recently changed his gardener, who took the lead in the management of his Orchids, and his new man does not appear to be so well up with them, for he called this plant a *Dendrobium*." Well, this remark tells somewhat against the employer, who should insist upon having every Orchid in his collection legibly and properly named; but with the plant in flower no one could mistake it for a *Dendrobium*, its sepals and petals being nearly equal, having a ground colour of yellow, with numerous cross bars of rich brownish-purple; the yellow lip is fringed in front; but I am not able to record any perfume, which detracts somewhat from its attraction, especially from the ladies' point of view. The plant is a strong grower, attaining some 3 feet or 4 feet or more in height, making stout, round bulbs, which bear towards the top numerous thin and strongly-ribbed, dark-green leaves, and from the point of the bulb from between the leaves the spikes appear bearing many flowers, which last a long time in full beauty. This is a plant which requires considerable space to grow it well, as it makes a great deal of root, and these roots are for the most part on the surface; therefore, the pan or pot should be well drained, and the soil used for it may be some good turfy brown peat, to which may be added a small portion of turfy loam and good leaf-mould, mixing with the whole some sharp silver sand. In the spring months, when the growth commences, it should be watered carefully; but as the bulbs lengthen a more copious supply may be given, and after flowering it may be kept somewhat dry; but, of course, at the present season, when it has its

blooms to support, it requires a good supply of moisture; but when these are past it may be moved into a cooler house, and have a less supply. I like to keep this plant in the East India house or a hot stove during its growing and blooming season, well exposed to the sun and light.

MATT. BRAMBLE.

CATTELEYA SPECIOSISSIMA.

From "G. Waterhouse" comes a flower of this Cattleya, but it is very poor both in size and colour. I have seen blossoms of this variety of C. labiata with fine large and broad petals which measured fully 8 inches across, with the lip very richly coloured. What then can I help saying to a flower of a poor washed-out colour which does not cover the measure at 6 inches? I do not say that mere size is the great desideratum in a good flower, but when one sees a flower of good size, with all the parts harmonising as to good colour and shape, then it is only rational that size will carry the sway. This plant is a variety of the now well-known labiata, but it grows, I should think, in a far warmer position than do most of the so-called forms, and the bulbs show it to be a very different plant to the rest of the varieties. The flowers are produced from these stems at various times, but always after the growth has been completed, and that accounts for my now receiving a flower. The plant is reputed to be a very shy flowerer; but this, I think, comes about only from mismanagement in its treatment of the variety; for if not grown in cool warmth, and the plants well exposed to the sun and light, so as to get the growths well ripened up, then I have seen them stand for years without ever producing a flower; but when treated right I have seen them produce flowers annually. This Cattleya has more varieties than any other of these labiata forms. Some people I know go in for calling this plant C. Lindleyana; but it appears doubtful if this is not another plant, so I will confine myself to the name by which it is known in English gardens.

MATT. BRAMBLE.

TRICHOPILOIA NOBILIS.

This plant some prefer to call Ptilonia nobilis, and others, P. fragrans nobilis, but under whatever name it is known it is a great beauty. This Orchid was introduced in the first place by M. Linden, of Brussels, who called it, if I do not mistake, P. fragrans grandiflora. "Peter Henderson" sends me a flower for its name, and "J. S." sends me at the same time the typical form of P. fragrans, stating it to be a white form of Trichopilia tortilis; but this is all a farce, for on looking at the spike sent I see that it has been two or three flowered, and this has been an erect spike, but the flowers had lost their fragrance, so that "J. S." may here take the name of his plant. The flower of "P. H." is, however, a very different affair, being both larger and stouter, and with a beautiful aroma. This is a plant well adapted to the wants and requirements of the amateur, for it is a beautiful species or variety, whichever you may like to call it, having pure white flowers, with a broad orange-coloured blotch in its eye, and having a fragrance resembling bitter Almonds. It is admirably adapted for a button-hole flower, and they last long in full beauty. Now, let me see what can be said for this plant; and the one feature that I can say is that it requires to be grown in the cool-house with the Orlotoglossum crispum and others that like cool treatment best, but yet they like more light than the majority of these plants do. They may be either grown in pots or baskets; but these must be well drained, and for soil use good peat and Sphagnum Moss. Water freely during the summer months, but more cautiously now and through the dull winter months.

MATT. BRAMBLE.

4942.—Gas-tar on hot-water pipes.—Scrape it all off at once and paint the pipes with lamp-black and oil.—E. H.

Callas in pots versus planted out.—Many different modes of culture are adopted with more or less successful results with these very popular plants, for they are very accommodating plants, and unless very badly done by do not fail to return good results. I have tried various plans, and have had the best success from plants put out in June and lifted in

September, especially when they were not required to flower very early in the season, for lifting and repotting, however carefully done, must check the roots, and, consequently, the top growth, and to get really fine plants, in comparatively small pots, I find that pot culture all the year round is decidedly the best. The plan now adopted is, as soon as the plants cease flowering and can be safely trusted out-of-doors, usually in the month of May or early in June, they are set out on a coal-ash bed, and do not get much water until the oldest leaves die down, when they are shaken out of their pots and all the offsets taken off, and the strong single crowns are repotted in 5-inch or 6-inch pots, using good rich loam enriched with quite rotten manure and sand. They are kept out-of-doors and carefully watered until September, when they are placed on light airy shelves near the glass, and get plenty of manure-water, and they push up very dwarf sturdy stems with leaves of the darkest green. By feeding liberally with liquid-manure, bloom quite equal in size may be obtained from plants in 5-inch pots to those in 7-inch or 8-inch without it, for Callas are such strong-rooting and gross-feeding plants that they will take any amount of rich food. The surface of the soil getting quite white with active roots, the flower-spikes are now pushing up strongly.

J. G., Hants.

TREES AND SHRUBS.

FLOWERING SHRUBS, ETC., FOR WALLS.

In reply to "Midlander," &c., amongst the most beautiful of these are the Clematises, and none are better than C. Jackmani (here illustrated), Honeyekles, and the White Jasmine and yellow winter-flowered variety are both of great value. Wistaria sinensis is very fine. Climbing

off the roots to a depth of 6 inches or more and from 3 feet to 6 feet away from the stem, and fill up the space with a mixture of good earth and rotten manure in equal parts. The other reason is that it is quite possible that the scion has not taken kindly to the stock. If that is so, whatever you may do to it will not benefit the tree in any way.—J. C. C.

OUTDOOR PLANTS.

BULBS PLANTED IN GRASS.

This is a good time for anyone desirous of trying this excellent plan of growing bulbs making a start, or the season will be lost. Many kinds of bulbs answer admirably; in fact, I never saw Snowdrops, Crocuses, and Daffodils in such fine condition as when grown in this way. The positions selected for bulbs should be where the Grass grows naturally rather thin, or where the partial shade of deciduous trees gives some shelter from rough gales of wind, but where they get the benefit of spring sunshine to call them early into bloom. Evergreen trees are too dense to plant under, but make good wind-screens, and recesses in shrubberies make good positions for trying this form of gardening. Snowdrops are such elastic and beautiful flowers that they are special favourites with many; they increase rapidly in the stiff soil of Kent, but here, on the south coast, they die away in a few years. Daffodils appear to thrive equally well anywhere; Bluebells are the same. Crocuses make a gorgeous display, if the birds would only leave their gay petals alone. Scilla sibirica is a little gem, and looks lovely on mossy banks or where the Primrose is at home, and in many a small garden there are waste corners overrun by fern and weeds that could be made quite beautiful by digging up the rubbish.

OUR READERS' ILLUSTRATIONS: Clematis Jackmani on a house wall. Engraved by GARDENING ILLUSTRATED from a photograph sent by Mr. Henry J. Fuller, The Village, Bexley, Kent.

Roses are indispensable. Cotoneasters do well, and also Escallonia macrantha, Aristolochia Siphon, and many of the Ivy, and, of course, the two Virginian Creepers (Ampelopsis), the older and best known one and Ampelopsis Veitchi, &c.

4936.—Unhealthy Weeping Aeh-trees.—There are only two reasons that I know of that would account for the unsatisfactory condition of the trees. One is that the soil is too poor and too dry for the Ash; probably the ground is so full of the roots of other trees, if the soil is poor you had better remove it from

Plant the hulls in good-sized clumps, then sow Grass seeds on the surface and await the result. If it does not fully justify your expectations, I, for one, shall be very much surprised.

J. GROOM, Gosport.

Hardy November flowers.—The outdoor garden need not be quite devoid of flowers during this month. If such hardy Violets as the Czar and the very large and fragrant Well-siana are well cultivated, they will begin to yield good blooms quite by the beginning of the month. The hardy Chrysanthemums are of the greatest value. They demand but little cultural

core, and in ordinary years they yield an abundance of bright blooms for cutting quite up to the close of the month. The old Cottage Pink, once very common here in Surrey, is a really good November flower. There is no hardier and more reliable Chrysanthemum for the open air than this. It is not generally known that quite a nice show of Pansies can be had during this time of year. I have now a tolerably large bed, the plants carrying an abundance of blooms almost as good as one generally has them in spring. Fourteen degrees of frost did not in the least mar their beauty. The seeds were sown in July and put out a few inches apart on good ground. *Jasminum nudiflorum*, the Naked-flowered Jasmine, is blooming with freedom, and the earliest of the Christmas Roses (*Helleborus maximus*) is already in flower.—BYLEET, Surrey.

4878.—**Outdoor plants.**—The greater proportion of hardy perennials may be transplanted now. It is indeed far better to do so at this time of year than to wait till spring, as the winter rains settle the soil round the roots, and most of them will begin to form new roots at once. They are thus better enabled to start strongly into growth the following spring, and are less liable to suffer from the effects of a dry season. Plants of hasty growth, such as dwarf *Caryophyllus*, the small mossy and ornamental Saxifrages, Primulas, &c., and fleshy-rooted things, such as *Lobelia fulgens*, *Alstroemeria*, &c., should not be planted until March. They must be well established to resist the cold and wet of the winter months.—J. C. B.

—It all depends upon what perennials you are going to plant. Such comparatively tender things as *Alstroemeria*, *Chelone*, *Pentstemon*, hardy *Orchids*, *Dielytra spectabilis*, *Lobelia fulgens* and its varieties, and such bulbs as *Anemone*, *Belladonna*, should not be planted until the spring, nor, as it is now so late, *Carolinianus*, which are best planted now in the spring. *Hieracium lobelia*, like, for instance, the other things mentioned, often get much cut up by the frost or wet of winter, and are best taken up and planted in a cold frame. But the majority of things—*Delphinium*, *Pyrethrum*, *Sunflowers*, and a host of other perennials I could name did space permit—may be planted now, or at any time during the winter when the weather is mild and the soil well worked. Plant firmly to prevent frosts injuring the newly-planted things, and if the beds or borders, as the case may be, want digging up, do this at once, and let the soil remain idle for a time, so that it may be thoroughly pulverised by the action of the weather. Read GARDENING carefully. You will get many hints from the replies to queries.—C. T.

4917.—**Japanese Anemonee.**—Now is an excellent time to plant these, and almost any portion of root will grow. They are not at all particular as regards soil, but like one of a rich nature best. "E. M. P." will find they need one season in which to become established before they show their full beauty and floriferousness. Recently I saw them doing remarkably well by the roadside, and I know of no flower which is less trouble when established. All they need being a slight mulching with rough manure during the early part of winter, and when their foliage is dead.—P. U.

—I consider the best time to plant these is just as growth is on the move in spring. They then get established at once, and if the crowns are strong enough they will flower the same season.—E. H.

4920.—**Plants for a shady spot.**—A list of the best shrubs for a shady place was given recently. There are not a great many plants that will succeed in shade, even if it is partial. Ferns of many kinds may be grown, Foxgloves, the fine Crown Imperials (*Fritillaria imperialis*), *Trisesis* if the shade is not very dense, *Creeping Jenny*, a well-known creeping plant, *Creeping Primrose* in variety, *Solomon's Seal*, *Polygonum cuscutatum*, *Saxifrage*, *S. hypnoides*, and *S. umbrosa*, *Sedum spectabile*; *Globe-flowers*, provided the position is neither too dry nor too shady, the winter-flowering fragrant *Coltsfoot* (*Tussilago fragrans*), *Vincas* in variety, and of bulbs the Spanish Squills, *Scilla campocaulata* in particular. One may get a variety of these varying from white to rose, and the plants bloom with great freedom. They make noble chumps. The Snowflakes will succeed also in partial shade, but not if the soil is too dry.

knowing your garden. At any rate, Squills, *Solomon's Seal*, *Lily of the Valley*, and the other things mentioned may be planted.—C. T.

—The most likely things to succeed are *Mahonia Aquifolia*, *Vincas* in variety, *St. John's Wort* (*Hypericum calycinum*). These will make pretty foreground plants if planted in groups somewhat thickly. Then behind these might come Box, Hollies, Yews, and Laurels. These also will look better planted in groups. Something should be done to improve the soil before planting.—E. H.

NEGLECTED PLANTS (ALLIUMS).

THESE, as a rule, are a class of plants seldom recommended for their beauty, either for rock-work or for the flower-border; yet to banish them altogether would be to deprive our gardens of a few really handsome plants, and plants, too, that can always take care of themselves without

Flowers of *Allium neapolitanum*.

extending beyond their allotted space. Their smell, if bristled, is against them, and although the Neapolitan Allium (*A. neapolitanum*), the flowers of which are beautiful and fragrant, is sometimes used in bouquets, this objection to it is always more or less felt. It is, however, a pretty border plant, and also can be grown in pots, and thus get in bloom earlier, and in company with *A. verulenum*, *Moly*, *scorzouerifolium*, and *pedemontanum*, undoubtedly useful and decorative; the last especially, with its numerous purple, drooping, Tulip-like flowers, is good enough for pot culture. *A. giganteum*, a species well named, growing, as it does, even taller than the well-known *A. siculum*. Its leaves are flat, strap-shaped, and of a light glaucous-green, and the flowers, though small individually, are of a purplish colour and collected in countless numbers into a large globular head from 2 inches to 3 inches in diameter. This sort is a decided acquisition. D.

4940.—**Plants for a herbaceous border.**—Here is a selection of plants averaging about 2 feet in height. Amongst white-flowered perennials select the Double White *Achilles*, *Anemone japonica alba*, which is taller than 2 feet, but so beautiful that one must include it; *White Antirrhinum*, a lovely flower, *Campanula Bells*, *Epilobium angustifolium album*, *Madonna Lily*, *White Lupine* (taller than 2 feet), *White Malva*, *White Perennial Phlox*, *Double Fair Maids of France* (*Ranunculus acemtifolius plenus*), *Trillium grandiflorum*, beautiful in late spring in a moist fairly shady spot, and the *White Scilla empannolata*. Of other things besides white one may choose *Aquilegia*, the dwarfed September blooming *Asters*, *A. versis* and *A. Anclasiu* in particular, *Delphinium nudicaule*, bright scarlet, the *Lyre-flower* (*Dielytra spectabilis*), *Genium coelestinum*, *Lilies* in variety, *Pyrethrum*, double and single, *Sedum spectabile*, *Campanula glomerata dahurica*, rich-purple flowers in close clusters; *Aionis vernalis*, yellow spring-flowering *Wallflowers*, *Coreopsis lanceolata*, *Erigeron speciosus*, *Rudbeckia speciosa*, *Globe-flowers* (*Trollius*), *Pansies*, and such things as *Polyanthuses*, *Auriculas*, etc. All the plants mentioned will grow well in ordinary borders, and are not expensive.—C. T.

4945.—**A garden in Surrey.**—Mulch the fruit-trees heavily with rich manure. What you really want is a few hundred loads of chyt to make the sand more fertile, and this would be as economical as manure if the chyt could be obtained within a reasonable distance. In the park, where some parts are very light, clay is carted there to dress the light soil. They

clay cannot be obtained, heavy manuring, and especially mulching, must be carried out. It is a difficult thing to make a sandy soil fertile; still, it can be done by perseverance. Salt will be found useful in hot summers.—E. H.

—I am afraid that you will not do much good with fruit-trees in your garden. The soil is too poor and too shallow for subjects that require a deep root-run, unless you remove the rock and fill up the space with fresh earth. You may do fairly well with Gooseberries, Currants, and Raspberries, if you give each plant plenty of room, and mulch the surface every winter with a thick layer of rotten manure. If you bear in mind when planting that as the roots cannot penetrate only to a certain depth, they must have an equivalent space in other directions, you may possibly get a fair return for any outlay you may make. Mulching with short Grass in the summer between all such crops as Peas, Beans, Onions, and Cauliflower, and thin sowing or planting, are operations that in such a case as this are indispensable to secure anything like success. Seeing that the sun sets on your garden all day you had better take out the rock to a depth of 8 inches or 1 foot for the flower-beds and borders, or they will not do much good in a dry summer.—J. C. C.

4899.—**Nitrate of soda on a lawn.**—I have many times written against the use of any of the artificial manures for restoring lawns in a bad condition, that I only wonder how it is we do not get more frequent complaints of their unsatisfactory character. This inquiry, however, refers to a case in which it has been used in excess, and the best thing for this correspondent to do is to take up the dead turf and replace it with fresh. For the benefit of the weak Grass which is left the lawn should have a dressing of short rotten manure or rich soil spread over it at once. Any money laid out on manure or soil as a top-dressing for lawns will do ten times more good than double the amount spent on any of the forcing manures. They are very well used in the summer as what I call a refresher for the Grass, but they do no permanent good. On special occasions, when I wanted the lawns to look particularly bright on a certain date, I have applied both guano and nitrate of soda ten days before the time, with the best results as a temporary improvement; but at the end of a month all trace of the benefit had passed away.—J. C. C.

—"Miss Eleanor Hughes," when applying nitrate of soda, was probably unaware of the power of the agent employed—namely, nitric acid. If used in excessive quantity and not properly distributed, nitrate would doubtless have the effect described, as, indeed, would ordinary manure properly used. Nitrate of soda should be employed upon Grass in quantities not exceeding 1½ cwt. to the acre, and the utmost care should be taken to secure even distribution. The nitrate should be passed through a sieve, and all lumps removed and broken up. For small lawns it is better to employ it in solution, at the rate of 1 oz. to 3 gallons of water, used once or twice weekly. The best time to apply nitrate is when growth begins in spring. To ensure good results it is essential that the soil be sufficiently rich in the other principal constituents of plant-food—namely, phosphoric acid and potash. This lady would do well to give the lawn at the present season a dressing at the rate of 3 cwt. superphosphate and 2 cwt. kainit per acre, and to apply in the spring 1 cwt. of nitrate per acre, mixed with double the bulk of fine, dry earth to secure even distribution. This will ensure a rich and rapid growth.—I. H.

4928.—**Sulphate of ammonia.**—This may be used more or less successfully for Potatoes, Cabbage, Cauliflowers, and all of the Brassica tribe, as well as for Turnips, Onions, Carrots, and other root-crops. Lettuces, Radishes, Turnips, Cucumbers, &c.; indeed, for almost everything, except Peas, Beans, and other leguminous plants, which are not benefited by nitrogenous manures—at least, not to the same extent as other subjects are, though, as a matter of fact, I have seen French Beans appreciably improved by a light dressing of ammonia. The best way to apply this powerful stimulant is in the form of a solution of the

strength of one ounce to each gallon of water, washing it off the leaves with pure water directly afterwards—that is, if it touches them. In rainy weather it may be sprinkled thinly and evenly between the plants at the rate of 2 lb. per rod, or 2 cwt. per acre.—B. C. R.

FERNS.

ADIANTUM CUNEATUM.

For every-day use, whether in pots or for cutting, it must be admitted that this fine old Fern is still in the front rank. With a good stock of plants it is always possible to have it in good condition. In many cases this Brazilian Maiden-hair is kept too warm. This is a great mistake, resulting in a general weakening of the plants, whilst the fronds will not last nearly so long when cut. For instance, during the summer I would much prefer to keep my plants in a cold frame rather than in a house with the least amount of warmth in the pipes. Again, a moderately dry atmosphere is far better than where it is moisture-laden. This latter state of things is congenial to rapid and free growth, but the fronds grow too large with correspondingly large pinnae, which are not in any sense desirable, whilst they do not last nearly so long when cut. They may look all very well upon the plant, but the plant thus grown will not bear a change to less congenial quarters, nor are the fronds of much use when cut. Shading, again, is a great mistake; it used to be a popular notion in some gardens that shading was really essential, whereas quite the opposite is the case, except in the very hottest weather. When

the shading is dispensed with, the growth is much harder, the pinnae finer, and the fronds, too, somewhat less in size, but supported upon foot-stalks considerably stouter. The paler colour, too, of the fronds when grown thoroughly well exposed is much more desirable for arranging with cut-flowers. The darker green, as seen upon plants grown in the shade is not nearly so effective; in fact, it is sometimes a difficulty to use it tastefully when of this shade of colour, bearing in mind also the larger pinnae. During at least six months of the year no fire-heat need be used, and only a very light shading when the heat of the sun is intense. A free circulation of air is indispensable towards securing a good enduring growth, whilst an abundant supply of water is needed when the plants are healthy, and the pots well filled with roots. When the latter is the case a weak solution of guano (Peruvian) in water will greatly assist the plants. This is often preferable to repotting twice in one season. In fact, potting is frequently carried too far. My best plants this past summer were those which were not potted last spring; these have continued in the best of health up to the present time. Overcrowding of the plants should be guarded against; they should now have all the light possible, not being overshadowed in the least by other things. Where there is any disposition to damp off in the case of the older fronds, these should be at once removed. Plants which have been yielding a good supply of fronds for cutting, and have become destitute of good material for the purpose should now be rested.

Water should largely be withdrawn from such plants; but little will be required between now and the end of the year. I would not hesitate to lay plants of this description upon their sides for a time, as long as they did not get excessively dry, particularly if they are still disposed to grow. It does not matter at all about the fronds dying off; in fact, a little later on they may be cut off entirely, thus clearing the plants of scale if there is any upon them. Take care that the plants whilst in this condition do not get any drip. When thus cut down, a spare shelf would suit them very well. These plants will make a capital stock to start early in the new year in a stove temperature, being meanwhile kept in a temperate house averaging about 50 degs. at night. When given an increase of about 10 degs. they will soon start into growth again, but the watering must be done cautiously until the fronds are well advanced. The best of these now in use will by that time be probably fairly well used up. These plants will then do with a rest, resting them later in the spring in less heat. Where there is a great

demand for cut fronds, it will be found better to have three batches in various stages rather than to rely upon two. In this way it is comparatively easy to have a ready supply. Plants that are now growing should have a fair amount of warmth, but not too much moisture.

A LIGHT AIRY HOUSE with a night temperature of from 55 degs. to 60 degs. will suit them well. The stove itself is rather too warm for them, even when they are growing freely; what some would term a cool stove would answer. Where there is a good quantity of growth still in hand, but fairly well hardened, a night temperature of 5 degs. less will suffice. In this way, by having plants in various stages, can successive supplies be mainly kept up. Young plants—i.e., seedlings, should be carefully looked after. These frequently come up in quantity; if not, it is an easy matter to sow the spores or to stand aside upon a moist bottom a plant bearing fertile fronds, and thus let the seedlings spring up spontaneously, which, after all, is as good a way as any. I prefer seedlings most decidedly to division of the old stools. They make much better plants, whilst if required whilst still in small pots, they are far more useful. When the older plants become exhausted and there is a sufficient stock of younger ones, it is better to throw them away or use them up for decorating. For general purposes, any pot beyond 8 inches or 9 inches diameter becomes too heavy and cumbersome. As to soil, I prefer all loam, with sand or road scrapings. When the loam needs modifying, a little leaf-soil or a small quantity of peat can be added, but not too much, as both tend to a strong growth. Potting is best done in the spring-time. A.

THE WALKING-LEAF FERNS (ANTIGRAMMAS).

In reply to several queries, all the plants mentioned in this part have not the properties of the old and well known North American Camp-

Frond of Antigramma Douglasi

tosorus (Antigramma) rhizophyllus, which spreads by rooting at the top of each frond where it forms a new plant, and from which it again sends out fronds which produce other plants. A few years ago, when I was with the late Messrs. Rollisson at Tooting,

ANTIGRAMMA RHIZOPHYLLA used to be imported in large numbers every year from Canada and found a ready sale. Many years ago, when I had charge of the outdoor ferneries at Hatchford Park, I had many a little colony of this plant, for it is quite hardy. The leaves which fall from the trees if allowed to remain will afford it ample protection through the winter months. The fronds of A. rhizophylla are simple, tapering to a point, where they are proliferous, and at the base are two large, ear-like lobes. The fronds are each about 9 inches long, and bright-green. It is found pretty freely in the United States and in Canada. Linnæus also gives Siberia as a locality for this species, but Hooker makes the Siberian plant a distinct species under the name of A. sibirica. It appears to differ in having a simple frond without any lobes at the base. The same form was found upon one occasion only by my friend Wilford in the Strait of Korea, on the Island of Taus Sima. Any reader who has a hardy fernery should plant this Antigramma in some light, turfy loam, choosing a nice shady place and keeping it tolerably damp.

A. DOUGLASSI (the subject of the illustration) is a somewhat rare plant in Brazil, and at present rare in cultivation. The fronds grow to some 10 inches in length and are about 4 inches broad. They are deep-green in colour, but non-viviparous at the point.

A. BRASILIENSIS has fronds each fully a foot long and about 2 inches or more wide.

Antigrammas are near to Scolopendrium or Hart's-tongue Ferns, but they have netted veins. The two last-named kinds require a stove temperature. G.

GOLD AND SILVER FERNS IN THE WINTER.

THERE is usually more harm done to these beautiful Ferns during the autumn and winter than during all the rest of the year put together. When the weather is dull, damp, and foggy the Gymnogrammas will require looking after closely to preserve them from decay. Where the fronds are large and the growth dense, this will be all the more likely to occur. Such plants want close watching; all the more so if they happen to be in a house that is predisposed to dampness. Those will be liable to suffer most which carry the heaviest coating of the farinae powder. For instance, G. peruviana argyrophylla is very apt to damp off a small piece here and there. This, in any case, should be stopped by frequent examination, removing the decaying pieces with a pair of Vine-scissors, either a knife or fingers not answering nearly so well. Old fronds turning yellow should be at once cut out entirely, and the others will be all the better preserved if drawn outwards in a careful manner. In houses which are somewhat flat, thus being liable to drip, a sharper watch still needs to be taken, or several fronds at once will be injured. When the weather is cold and frosty with an extraordinary amount of heat in the pipes, there is the liability of the plants getting too dry at the roots. They are extremely sensitive in this respect. In the case of some of the Adiantums and Aspleniums it does not so very much matter if they be dry at times. Not so in the case of the Gold and Silver Ferns. The plants should, if the previous culture has been good, have plenty of roots, the pots not out of proportion to their size for wintering. Then the plants will take a liberal supply of water with no risk of an overdose when looked after in a careful way. A good place for wintering Gold and Silver Ferns is the narrow shelf oftentimes to be found next the path on the front side in lean-to plant-houses; under these narrow shelves the pipes will in most cases be arranged. Thus the position is a dry one—drier, in fact, than most plants like it, but not too dry for those under notice. Of course, the watering in such a place is an all-important matter, but when so well within notice there is no real excuse for any omissions. The Gold and Silver Ferns, although they enjoy warmth, may also be used freely in the winter as decorative plants. They are not often seen shown in collections of table plants, but, all the same, it takes an exceedingly good plant of any other family to beat them, they are, in fact, the Gold and Silver variety, so very appropriate to the dinner-table when the latter is well laid-out. It is possible that stray

seedlings may in some cases be now of fairly good size; these might at once be lifted with as much soil as possible and potted, keeping to as small pots as possible. These young ones will then with the turn of days start off into growth more freely by a long way for this early attention. F.

4937.—**Ferns not thriving.**—Evidently you are keeping the Ferns far too warm, or perhaps the fronds are naturally of a pale-green colour. Some kinds are, but we suspect the cause is too much heat and insufficient ventilation. Well, if in a stove it will not be necessary to give air, or at least very little, and the stage and in between the pots must be kept well moistened. Perhaps they require repotting; if so, wait until the turn of the year. Ferns, when they get rather old, often look weakly. A conservatory should be ventilated on favourable occasions, but be careful not to admit keen draughts. You must exercise judgment.—C. T.

—Too much heat and moisture, with insufficient light and air, are the most probable causes of delicate growth and want of colour in the fronds, but at the same time it may arise from some other cause, such as the want of some principle in the soil or water. Ferns require more water, both at the root and in the atmosphere, than most other classes of plants, and especially so when grown in a high temperature, and the soil ought really never to become anything like dry at any time, but at the same time a sodden state of the soil, induced by frequently giving water before it is required, must be avoided. At this season Ferns need very little ventilation, and less than most things even in the summer-time. The roof ventilators may be opened a few inches for a couple of hours in the middle of mild or sunny and comparatively warm days, but beyond this nothing is required. A little soot dissolved in the water occasionally will often improve the health and colour of the plants considerably, and a weak solution of nitrate of soda once a month in the growing season is also very beneficial. The proper ventilation for a large conservatory depends chiefly upon its temperature and contents. If kept warm, no air is necessary, but if cool, give air freely on all mild days.—B. C. R.

4818.—**Ferns for a heated conservatory.**—*Pteris tremula* is a very handsome Fern that in time attains a large size, especially in a genial temperature, such as your conservatory would appear to afford. It may be either planted out or grown in large pots. *P. argyrea*, with variegated fronds, is also fine, and of free and large growth. Another Fern that would suit you for a similar position is *Nephrolepis exaltata*. If you want a greater variety among the large kinds better procure a few *Trochium*, and some *Palms*, such as the *Kentias*, *Latania borbonica*, etc., would also do well and afford a nice variety. Lower down you may place *Lomaria gibba*, *Asplenium cavatum*, *A. bulbiferum*, *A. lucidum*, *Phlebodium aureum*, *Pteris majur*, *P. serrulata* and others, and towards the base *Adiantum* of sorts, *Asplenium recumbens*, *A. monanthemum*, Mosses (*Selaginella*), etc. Of these last almost any of the greenhouse kinds would be suitable, such as *S. Kraussiana*, *S. Martensii* (large), with its variegated form *S. strobilifera*, etc. Tufts of the pretty drooping *Isoplepis gracilis* here and there would also have a nice effect. All the Ferns, etc., mentioned are such as thrive in the comparatively smoky atmosphere of London with ordinary care. Whatever you do, be careful to provide plenty of atmospheric moisture, without which nothing but failure can be expected.—B. C. R.

4886.—**Primula obconica.**—In GARDENING for November 11th, "Constant Reader" inquires if *Primula obconica* is a dangerous plant to grow? It may be mentioned that Dr. E. B. Peckey (*The Lancet*, 1893, page 103) records the fact that a market gardener was accustomed to grow this plant, and after recovering from an attack of erysipelas he was allowed to resume work in his greenhouse, whereupon the disease immediately reappeared. This having occurred several times, his medical attendant advised him to remain in the house for a longer period; but after resuming his work the disease broke out again, and in all there were six relapses. It was discovered that the patient was accustomed to

work the pale-lilac flowers of *Primula obconica* into funeral wreaths, and that this plant emitted a poisonous substance which caused the relapses of erysipelas already alluded to. Consequently, persons susceptible to erysipelas should avoid coming into contact with this plant.—J. H., 220.

"Give a dog a bad name and hang him," is an old saying, and, unlike some old saws, it contains a good deal of truth. As far as I know the plant is perfectly harmless. No one wants to eat it, and if the leaves were chewed and swallowed the result might not be pleasant; but I have handled the leaves and roots again and again, and repotted the plants at all seasons with the result that no inconvenience of any kind has resulted therefrom.—J. D. E.

INDOOR PLANTS.

SALVIAS INDOORS IN WINTER.

Few assisting in the embellishment of greenhouses and conservatories during winter and spring there are few things more showy and

Salvia patens.

useful than Salvias, especially such as *S. splendens* and its variety, *S. Branti*, and the old *S. Heeri*, which is by far the best and most effective for the spring. *S. splendens Brantii* is a remarkably fine kind, and a great improvement on the one from which it originated, as it is of a better habit and has larger spikes of flower of a much lighter colour. The plants, too, have better foliage, being more serrated, thicker, and of a more glossy green. I find it also hardier, although to have it in perfection it needs more heat than is generally kept in an ordinary greenhouse. In a temperature ranging between 50 degs. and 55 degs. it sends up its long bold scarlet spikes of bloom in succession nearly the whole winter through. *S. Heeri*, on the other hand, is very impatient of artificial heat, which, if given for any length of time with a view to force it or bring it out before its season, is almost sure to spoil it, as not only do the plants grow up weak and spindly, but the blossoms come waxy and poor. In order to have

LARGE SPECIMENS it is necessary to put in cuttings in February or March; but as smaller plants are generally the most serviceable, a batch should be put in later, and another lot some time in July or August. These latter may be grown in 6-inch pots, and will be found to come in most useful for window decoration, a purpose for which they are specially adapted, as they look well in boxes associated with small white *Chrysanthemums*, *Carnations*, or *Eschscholias*, and produce a dense and pleasing effect. In a greenhouse placed between or near large plants of *Chrysanthemums*, *Salvia splendens* and *S. Branti* is particularly striking as it bright-

up the whole by the brilliancy of its colour. The way in which these Salvias should be managed is to pot them off singly when struck and keep them gently growing on in any frame or pit where they can have a little heat to the end of May, when they should be gradually hardened preparatory to exposure in the open air, where they always do best during summer, as there they grow short-jointed and stocky, and keep cleaner and healthier than under glass. To prevent the sun acting on the pots, it is advisable to have them plunged in some loam, open material, such as straw or leaves, which keep the roots cool. The most suitable soil to grow Salvias in is good fibry loam, and as they are gross feeders, they are benefited by frequent applications of liquid-manure, especially after they have filled their pots with roots, and are approaching the time when they begin to show bloom—a period when they cannot well have too much, if the

Liquid-manure is not strong and rank. By the middle or end of October it will be time to put the plants in a house or pit to protect them, for if left out in the cold after that they begin to lose their lower leaves, and get themselves discoloured, which detracts from the beauty of the plants when they get into bloom. Some grow their Salvias in the open ground instead of in pots, and it is a good plan in cases where large specimens are required, as, by having more root room, they attain a larger size, and can be taken up and potted early in the autumn. If this is done with care during a dull, showery time the plants sustain but little check, as they soon get hold of the fresh soil and become re-established.

SALVIA HEERI does best wintered in a cool, airy house, where it can have plenty of light, and, like its congener *S. splendens Brantii*, should be well fed with liquid-manure. The natural time for *S. Heeri* to flower is about the middle of March, and it continues to last in full beauty for quite a couple of months. As cuttings made from the young fresh growth are best, the old plants, when they have done blooming, should have their branches shortened, and be then placed somewhere in a gentle, moist heat to give them a start, when the young shoots may be taken off, and if put in the propagating box, in cutting pots, in the ordinary way, they soon strike root.

SALVIA PATENS (here figured) with its unrivalled blue blossoms, is a very desirable variety for pot culture; but to have this good late in autumn it is necessary to keep it pinched back, and grow it in a sunny position outdoors to get the growth hardy. Being tender-rooted, this kind may be kept from year to year, in the way in which Dahlias are kept, and may be increased either by division or cuttings. The only insects that nibble Salvias are green fly and red spider; the latter may easily be kept off by syringing in the evening after sunny days, and the former in the same way with weak Tobacco-juice, or fumigating the plants when placed under glass—a precautionary measure that should always be taken before they come into flower. S.

4918.—*Himantophyllum splendens.*

The *Himantophyllums* are not difficult to grow, and require a warm greenhouse. The plants must be grown on throughout the year, and in potting use a good, loamy soil. You should be able to succeed well with them if you have a warm greenhouse, but they are not much account unless this can be provided. There are many varieties of *Himantophyllum minimum*—*splendens* is one of them—and the various forms run through many shades of colour, from quite a yellowish-buff to deepest orange-scarlet. Individually the blooms are of use to cut, and a display is maintained over a long season.—C. T.

4938.—**Lilies in pots.**—*Lilium speciosum* variety *rosennii* will succeed either in pots or planted out; but the bulbs had better not be dried at all. Pot them as soon as they are taken off, and half-a-dozen offsets may be planted at once in 5-inch flower-pots. No offsets should be washed, but they had better not be taken off until they separate readily from the old bulbs, with plenty of good roots attached to them. When the bulbs are potted they should be plunged in Cocoa-nut fibre refuse or something of the kind to the rims. They will do out-of-

HEATING GLASS-HOUSES.

THE return of cutting winds and frosty nights brings the question of heating our glass-houses and pits prominently before our notice, for the very life of our plants depends on the right temperature being maintained. Now I have no hesitation in saying that it is by far the wisest course to grow only hardy or half-hardy plants in preference to those that need a higher temperature if we cannot give that temperature to them, for all our work in other ways will be lost, and plants grown in cold-houses that need warm ones will yield nothing but a crop of troubles and losses to the owner. There it, happily, no lack of varieties suited to cold, intermediate, or hot-houses, and, to prevent disappointments, make up your mind what classes of plants you will grow, and arrange your heating apparatus accordingly. After a good many years' experience of glass-houses and boilers I can safely say that to be on the safe side you must have a good reserve of heating power, for the following reasons: Boilers of many kinds are advertised to heat so many hundred feet of piping, and, as a rule, they will do so when first fixed up, with all the flues, chimney, &c., as clean as a pin; but to test them properly you want to personally stroke them for a month in the middle of winter, and you will find that, as a rule, too much is expected of a boiler, far in addition to the ordinary house or houses which it can warm easily one or two more are often added on that only need a little heat to keep the frost out. But it must be borne in mind that at this critical time a good deal more heat is needed in the pipes to keep the ordinary temperature up, and if you only warm the pipes in the extra houses the boiler must be driven at the highest pressure to meet the strain, and we all know that overdriving a boiler is very similar to overdriving a horse, and accidents are often the result. I would, therefore, strongly urge all who are having boilers fixed to have one capable of doing more work than is needed. Its cost will be more than saved by the safety of your stock of plants, and by the saving in fuel, for driving a small boiler wastes more fuel than letting the fire in a larger-sized one burn on gently. With the heat well assured you can close the dampers and keep the heat enclosed about the boiler, whereas with a smaller one, with a fierce draught to get the heat up, a great deal of the heat is driven up the chimney, and with the high price of coal it is a great saving to have a boiler large enough to burn coke, cinders, wood, or any combustible refuse. A small boiler must have only the best fuel if the maximum heat is maintained. I know some large forcing establishments where, by having extra large boilers and furnaces, they get plenty of heat from ashes collected by the scavengers. But the size of the fire insures plenty of heat, and if coal is going up to famine prices it will make growers for profit look to some less expensive fuel than coal, otherwise the cost of production will exceed the market value of some kinds of goods. Amateurs who frequently have inferior fuel to burn will do well to see that their boilers are large enough to allow of second-rate fuel being used—in fact, smoke-flues may possibly come into use again if coal goes up over £2 per ton.

JAMES GROOM, Gosport.

4881.—**Foliage Begonias.**—I presume you mean simply Begonias for their foliage alone, as some are very beautiful both for leaves and flowers. At my rate, I will name a few in both sections. The former class, known as the Rex, because resembling that well-known foliage Begonia, are very charming when planted out in a cool fernery, the silvery tone of their leaves being in strong relief to the green of the Fern-fronds. I should advise you to ask the nurseryman for a selection, or pick out those that please best. Arthur Mallet is the best of the darker-coloured varieties; but there is a host of a named sorts, La Candour, Colonel Demfer, Frederick Schneider, Unique, Adrian Schmidt, and Duchesse de Brabant. Two very fine winter-flowering Begonias, with leafage as rich and beautiful as the flowers, are Gloire de Secaux and President Bonnevilles, the former with bronzy leafage, very rich against the pink flowers, and the latter very dark also, the flower of a pink shade.—C. T.

4922.—“**Malmaison**” **Carnations.**—The varieties of Carnation Souvenir de la Malmaison are very liable to be attacked by a troublesome disease, which appears in the form of brown spots upon the leaves termed *Uromyces coryophyllinus*. The remedy for this disease is given in GARDENING, November 11th, page 500, which is to cut off the affected leaves and destroy the spores of the fungus before they have time to do any harm. There is another disease termed “spot” by gardeners, which appears on the leaves in the autumn. It generally develops in damp, close weather, when the plants are out in garden frames. The disease is most troublesome in damp, cold seasons. The name given to it by the specialists is *Ureda Dimthii*. The disease does not spread in a dry atmosphere. Pick off the diseased leaves, and place the plants in a greenhouse.—J. D. E.

4923.—**Aspidistras.**—The *Aspidistras* chiefly grown are *A. lurida* and *A. lurida variegata*. The variegated variety when grown in rich soil does sometimes turn green, and the best way to prevent it going back is to grow in peat and sand, using plenty of sand. *Aspidistras* are so easily managed that I have never heard anyone say they have failed with them. Some of the handsomest specimens I have seen have been grown entirely in rooms. The chief thing is to water carefully, avoiding at this season giving too much, and if the plants stand in an ornament-jug or jar, empty the water out every week, and the leaves must be kept free from dust by sponging or wiping with a soft cloth.—K. H.

—There are several kinds of *Aspidistra*, the best being *A. lurida*, introduced from China in 1822, and the variegated variety. A *punctata*, is also a Chinese species, introduced in 1824; *A. elatior*, came from Japan in 1835, and its variegated variety in the same year, and from the same country. But judging from your query I should think you want no others except *A. lurida* and its variegated variety. The best way to maintain the variegation of the plant is to keep the soil moderately poor. Rich composts and feeding produce gross green growth. Start with well marked specimens, and, as regards their winter management, the subject has been treated at length recently. Be careful about the watering, giving no more water than will keep the soil moderately moist, and on occasion of severe frost place the plants in the centre of the room to avoid any possible mishaps. Sponge the foliage regularly and carefully, using tepid water. This is most important, as during the winter the foliage gets coated with dust and dirt. These are the details to consider, and when followed make healthy plants.—C. T.

4923.—**Eucharis and Amaryllis.**—The *Eucharis* would do admirably in any house, the temperature of which is 55 degs. to 60 degs. at night, with an increase of 10 degs. more by day. They do not want a great deal of water in winter, but should not become very dry at the roots. The *Amaryllis* should now be resting in a greenhouse temperature, and be kept quite dry at the roots until the month of January, when it is usual to repot them and start them into growth again. The *Amaryllis* would be more liable to damp off from excess of water after repotting than *Eucharis*. I do not give them any water for three weeks at least after repotting, but the flower-pots are plunged in a heated bed and not in a very high temperature at first.—J. D. E.

4880.—**Fuchsias from seed.**—Raising *Fuchsias* from seed in the hope of getting new and improved varieties is tedious work. There is no actual difficulty in raising them; but it is rare, indeed, to get a variety that is better or distinct from the hundreds already in cultivation. Still, there is a distinct pleasure in raising seedling *Fuchsias*, as it may occur that you will get a really good novelty. In raising, study always the variety well, not merely as regards the colour of the flowers, but to see that the plant is of good habit of growth, free, and other points are taken into consideration. Thus, for instance, it is wise to cross a weakly growth with one of stronger habit. When the varieties are fertilised, keep them distinct—that is, do not mix them up with others. The berries must remain upon the plant until they are quite ripe, when gather them and remove each seed one by one from the pulp, the best way being to use a blunt

knife. Then lay out the seeds upon paper to dry, and when this is the case, wrap them up in paper and lay by in a drawer in a dry room. Early in the spring sow them in pots or shallow pans filled with light soil. Provide plenty of drainage, and cover the pans or pots, as the case may be, with paper until the seed has germinated. I may say that a warm corner of the greenhouse will suffice. When the seedlings are ready to handle, prick them off in pans or pots, and from thence, when of sufficient size, they may be transferred singly to small pots, using the same kind of soil as previously advised. There is considerable difference in the time the seedlings bloom, some being later, and some earlier than others.—C. T.

4920.—**Cinerarias in a cold frame.**—*Cinerarias* will do me good in a cold frame at this time of the year, as they will be injured by frosts. They do not like too much artificial heat either, enough only should be used to keep out the frost. Pour the water in at the sides of the pots, and it would be a grave error to water them over the leaves with a rose pot at this season. It would be well to get them out of the frame into a house that can be heated sufficiently.—J. D. E.

—*Cinerarias* are hardly safe in a cold-frame now. It is possible, of course, to keep out frost by using heavy coverings, but if there is room in any house where the frost can be kept out they ought to be taken there. Plants in a cold-pit should not be watered overhead now.—E. H.

4917.—**Vallota not flowering.**—As the plant flowered two seasons, and has not done so this year, the reason seems obvious. The plant, not having had any fresh soil in the roots for more than three years, should be repotted. Do it in the spring carefully, removing some of the offsets, but not disturbing the old bulb.—J. D. E.

—I expect the plant is starved. Repot it next April using rich sandy loam, with a little leaf-mould and peat. Water it freely during the summer, give it a good roasting in the sun in August, and it can scarcely fail to bloom well in September. Do not let the soil get very dry during the winter; being an evergreen it requires water, more or less, at all seasons, though not nearly so much in cold weather as hot.—R. C. U.

FRUIT.

PEAR “FLESH BEAUTY.”

IN reply to “R. B.,” “D. S.,” and others, this Pear, of which we give herewith an accurate illustration, is, so far as our experience goes, very good in a hot, sunny season, being large in size and excellent in shape, with a smooth, shining skin, which, when fully matured, is of a soft yellow colour, suffused with deep-red on the side next the sun. The flesh is white and melting and aromatic in flavour. It does best planted against a wall with a southern or western aspect, in which case it should be gathered the moment there is the slightest indication of maturity, as, if left to ripen on the trees, its season is soon over, and it is not nearly

Pear “Flesh Beauty.”

so good in flavour. It would be interesting and instructive to many if some of our Pear-growing readers would give us the benefit of their experience with regard to the merits and faults in question.

4898.—**Pruning a Vine.**—The pruning of a Grape-Vine is the simplest part of Grape culture in my opinion. Do not be in a hurry about pruning the Vine; let the leaves all fall first. If the house is used only for the Vine leave the ventilators open night and day to get the wood well ripened. I should defer pruning until after Christmas, though you can do it at any time after the leaves have fallen. Cut the

young growth back as close as you can to the main stem. Some gardeners cut back to the second eye; this plan in a few years produces large, ugly spurs. I prefer cutting closer, providing a good bold eye shows at the base, as one eye is quite enough. The main shoot shorten back to a few inches of old wood.—J. BOYES, Rugby.

4877.—**Moving Apple-trees, &c.**—"E." could not direct a better time than the present for moving fruit-trees of any kind. The ground is in such splendid condition, not too wet nor too dry. It works freely without battering the young roots. "E." need not trouble about the leaves, as these are ripe now and ready for falling, therefore the moving will not in any way injure the trees, and by moving them now they will soon get established for next year's work. Get the holes dug out large enough to receive the roots. Take up the trees with a good ball of soil attached and plant them the same depth as before. Well mulch with long manure or litter of some kind.—J. BOYES, Rugby.

4932.—**Fruit-trees in pots.**—The plants should be kept moderately wet at the roots in winter. Excessive dryness is very injurious; it causes all the tips of the active rootlets to shrivel considerably, and many of them die outright. The result is what anyone acquainted with plants and trees would expect—the blossoms open badly, and many of them drop off instead of setting, causing a partial or perhaps total failure of the crop. The house should be kept well aired, and if severe frost sets in the pots should be plunged up to or over the rims in Cocoa-nut-fibre refuse, or if this is not available some straw or loose litter may be placed over and around them to keep out the frost.—J. D. E.

—Keep the trees moderately moist. If permitted to get thus dry some, perhaps most, of the flower-buds would drop.—E. H.

4948.—**Early Strawberries.**—As you do not want to start the vinery early, nor yet to obtain very early fruit from the Strawberries, there is plenty of time yet to begin to think about forcing the latter. Supposing that you begin using fires in the vinery some time in February, or not later than the 1st of March, that will be soon enough to start the first batch of Strawberries, and the rest can be brought in, say fifty at a time, at intervals of ten days or a fortnight. They will do very well on the shelf mentioned—in fact, you could not have a better place for them; but the more sun they receive the better, especially while the fruit is swelling off and ripening. To do Strawberries justice, however, they should be kept in a temperature not exceeding 45 degs. at night until the blossoms expand; if there is an empty pit available it is a good plan to start them there, plunging the pits in a bed of leaves or tan. Otherwise you must do the best you can with them in the vinery, but keep up a moist atmosphere during the early stages particularly, or red-spider will be very troublesome. In the meantime the pots ought to be protected from severe frost in some way. With this subject they may all be accommodated on the floor of the vinery for the present, with plenty of air in mild weather, or they may be plunged in ashes in some sheltered spot, covering the tops with some dry litter, straw, or Fern, during sharp frosts.—B. C. R.

4941.—**Vine-roots going down.**—The only way to keep Vine-roots from going down is to provide plenty of suitable food on the surface, and not let the surface of the border get dry, especially during the growing season. Vine-roots will go down for moisture. During summer every Vine-border should have a mulch of manure on the surface. This is very important in the case of inside borders. It would have been better if the Vines had been lifted a little earlier. In the case of late Vines now, I should delay the lifting till February, as they will not remain dormant so long.—E. H.

4921.—**Pruning Fig-trees.**—Fig-trees should not be pruned at this season, but all the young fruits which are as large as Horse-Beans should be pulled off, as they will probably perish during the winter. The best time to prune Figs is in summer. The pruning should begin early in summer by thinning the young shoots when growing, and this thinning should be continued from time to time during the summer months, as required, as it is only by keeping the growth

thin that it can be ripened perfectly. Away from the south coast Fig-trees can scarcely be considered quite hardy, and it is quite wise before severe frost sets in to unvail the branches, draw them together, and cover with mats or straw. Uncover and retrain about the end of March or beginning of April, and any further pruning which may be required should be done. The spring is a good season for cutting out naked branches, with the view of filling in with young wood.—E. H.

4903.—**Gooseberry-caterpillar.**—This is a very good time of year to remove the soil from beneath Gooseberry bushes, but it is best to put the line on in the spring. The object of removing the earth is to take away the cocoons or chrysalides of the insect which are found in it about 2 inches below the surface. They are small dark oval bodies about half an inch long. They are sometimes found singly, but if a great number of caterpillars have attained their full growth on a bush, the cocoons may be found in considerable numbers more or less joined together. When the perfect insects are just leaving their cocoons and making their way to the surface, lime should be sprinkled on the ground, which will probably kill them before they have attained their purpose. The ground which has been removed should be burnt or spread out where poultry can scratch it over, and the fresh earth used to replace it should be taken from a part of the garden not likely to be infested with this insect. If this plan was carried out by everyone who grows Gooseberries, the Gooseberry Saw-fly, which is the parent of these Caterpillars, would soon be almost extinct.—G. S. S.

4926.—**Cape Gooseberry.**—This is the last plant that I should think of investing in for market purposes, if for no other reason than that not one in a hundred people know what it is. That being so it will take many years to educate the public taste for it, even if it possessed the required excellence as a dessert fruit, which I very much doubt; and looking at the unhappy condition of a plant in my cool greenhouse as I write, solely for the want of more warmth, it does not impress me as being a subject at all suitable for cultivation for commercial purposes, as it evidently wants a good heat to ripen the fruit at this time of year.—J. C. C.

—I should say the Cape Gooseberry will be of no use for market. Market people do not take kindly to innovations, and the plant is not a heavy cropper, especially in winter, and we are not likely to have cheap fuel again for some time. Seeds may be obtained from any of the large seed houses. It is known as *Physalis peruviana*.—E. H.

Peare on a clay soil.—With reference to the answer to Query 4788 on this subject (on p. 504), I am afraid that "J. D. E." is not quite correct in stating that Pears do well on a clay soil if worked on the Pear-stock. Now according to all my experience and knowledge of the subject the stock for Pears whenever the soil is of a heavy or clayey character is the Quince; for this reason, that being essentially a surface-rooting subject, it keeps the roots near the surface, within reach of the sun's warmth and fresh air. The roots of the Pear or natural stock strike deeper, and once they get down into the solid clay beneath the trees run away to grass woad, and produce little or no fruit, and this tendency can only be checked by frequent root-pruning, a thing very seldom necessary in dealing with plants on the Quince. My advice to "Reader" is to obtain plants of such hardy and productive kinds as the Hessele, or Hazel, Fertility, Beurré Clairgean, the Crawford, Beurré de Capiaumont, Autumn Bergamotte, etc., on the Quince, and plant them right on the surface, merely digging up the topsoil, and covering the roots with soil brought from elsewhere, or taken from between the rows. "E. H." (p. 487) is right when he says "Avoid deep planting; I would rather plant only a few inches deep and cover the roots with a mound of soil." We are on the stiffest of stiff clay here, and I have been similarly situated before, and know what can be done. Choose the right kinds (even the favourite Pituraston Duchess can be managed), and plant them as directed, and all will go well.—B. C. R.

4925.—**Pelargoniums, Tea Roses, &c., for market.**—"Mr. Fleming" is asking a somewhat indefinite question, as the amount of what necessary depends so entirely upon the

time he requires bloom, as well as the state of growth his plants may be in. Roses and Pelargoniums need widely different treatment; while the former enjoy the syringe—and cannot well be grown without—the latter would be quite ruined by its use. Early flowers need early starting, a steady growth being much the best, especially at first. As a slight guide I may advise a temperature of 55 degs. to 60 degs. until the early part of December, rising 10 degs. through that month, and with a slight increase early in the year.—P. U.

—A night temperature of 55 degs. will suit them very well. They will bear a little extra pushing on an emergency, but the temperature given will suffice. With air on the temperature may rise during the day when the sun shines to 70 degs. or more.—E. H.

4804.—**Mealy-bug on Tacsonia.**—If you cannot syringe your Tacsonia, the only way is to wash it, taking care to hold something under the part you are at work at to prevent any drips. If you want to get rid of this insect I should cut away as much of the plant as you can, and then go very carefully over the rest with a small, stiff brush and a sponge, and some soft-soap and Tobacco-water, or soft-soap and paraffin (one wineglassful of oil and double that quantity of soap to three gallons of water); dissolve the soap first in some hot water, and while hot stir in the oil, and then add the rest of the water. Be sure and keep the ingredients well mixed.—G. S. S.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 37, Southampson-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as remain well classified, will be found in their respective departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising us, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, rules, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

4900.—**Making cider.**—Would someone kindly give a receipt for making cider?—C. B. C.

4901.—**Cucumber-plants for sale.**—Will anyone kindly tell me the best way to raise Cucumber-plants for sale?—J. B.

4902.—**Planting Gladioli.**—Will someone kindly tell me the best time of year for planting Gladioli, and what soil is best?—D. C.

4903.—**Storing Turnips.**—Will someone kindly tell me of the best way of storing Turnips in order to keep them from the frost?—FRONTINUS.

4904.—**Planting Raspberries.**—I should be glad of a few hints as to the best way of planting Raspberries, and the names of one or two of the best sorts grown?—THEOBALD.

4905.—**Potatoes in a house.**—I have a large well heated house planted with Potatoes, and shall be glad to learn particulars as to temperature and general management?—F. W. S.

4906.—**Wash for plants.**—Would "Arthur Elson" kindly tell me how much paraffin-oil and milk to put with one gallon of water to make a safe wash or dip for pot-plants?—REMBE.

4907.—**Worms on a lawn-tennis ground.**—I have a lawn tennis ground where the worms throw up the earth so much that the court is perfectly useless. Will anyone kindly tell me how to remedy this?—J. H. U.

4908.—**Rose W. A. Richardson.**—Will this Rose grow outside in a south-west exposure, and will it be safe to put it out now or keep it in an unheated house—south-east—exposure till the spring? Should it be cut back, and when?—J. W.

4909.—**Quick-growing Ivies.**—I should be obliged if someone will tell me the names of Ivies to grow quickly and cover an out-house well? Aspect, S.E., but in a shady corner and under trees. Also, when should they be planted?—J. F. M.

4910.—**Forcing Rhubarb for market.**—Will someone inform me what sort of houses or other buildings are used by market-growers for forcing early Rhubarb? Also, what mode of treatment is used by them for forcing and blanching it?—ALPHA.

4911.—**Draining a garden.**—On starting a large vegetable garden on a clay soil in Essex I am anxious to obtain information how to set about drainage. Can it be accomplished by ordinary labour, or must it be by contract, and at what expense?—C. F.

4072.—Compost for Tomatoes.—I have some soil which is not very rich. I am thinking of mixing with it rotten-manure and leaf-mould. Is such a mixture good for Tomato-growing? Is leaf-mould good? Would it do for top-dressing during summer?—TOMATO.

4073.—An unheated frame.—I have a small unheated frame about 4 feet long and 2 feet 6 inches wide by 2 feet high? Would it be possible to grow a few of the hardier kinds of Orchids in it? If so, should be glad to know some of the best varieties?—LARRY'S STRAZZ.

4074.—Good loam.—Will someone tell me what is generally meant by "good loam," and where it is likely to be found in country places (Monmouthshire)? Would mole-hills mixed with leaf-mould and sand answer the same purpose for general potting compost?—CONSTANT READER.

4075.—Cacti from Mexico, &c.—Will someone kindly put me in the way of procuring Cacti and other plants from Mexico or Central America, but, if possible, not through dealers? I am in a complete fog how to set about it. Any information would be most welcome.—CERREYS.

4076.—Badly-coloured Beetroot.—My Beetroot when boiled is white and stringy. No frost has got at it, and has been taken out of the bed it grew in with great care, and no roots were broken. Variety, Whyte's Dark Red or Black. What is the cause of its being bad in colour?—IRELAND.

4077.—Vegetable-manure.—I have a quantity of vegetable-manure, the collection of 1892. It is nearly rotted into mould, short and crisp. In thought of dressing my herbaceous beds with it. Would someone please say if it is suitable, and whether I ought at once to dress the beds with it or wait till spring?—J. B.

4078.—Flies on fruit-trees.—I have Peach-trees on a south wall, which, when the sun is out, are completely covered with large flies. Will someone inform me how I can get rid of them without injuring the trees? Cannot the wall be washed with some preparation on a dull day when the flies are in the crevices?—HONORABLE.

4079.—Lime-trees.—Will anyone kindly give me replies to the following questions?—1, Which variety of lime-tree (Tilia) blooms most freely?—or are all varieties about equal in this respect? 2, At what age does this tree first come into bloom? 3, How should they be propagated, and during which season? Any other detailed particulars will be very acceptable.—T. B.

4080.—Marchal Niel Rose in a pot.—I have a Marchal Niel Rose in an 8-inch pot that was potted three months ago. It has made a very slight start as to growth, but is showing buds with it. The shoot, which is 2 feet high only, and is therefore a very small plant. Shall I leave the bud on or take it off, as I want the plant to grow quickly? It is in an unheated lean-to house, with a south-east exposure.—J. W.

4081.—Growing Clematis.—I am anxious to grow some autumn-blooming Clematis on short iron posts, and trained to form a continuous line from one to the other. What ought they to be trained on? The posts will be 2 1/2 feet high. I should be greatly obliged for any hints as to kinds and their treatment. I would rather have a few sorts of kinds than a great variety. There will be at least thirty-six posts, and would 12 feet apart be too far?—KATIE.

4082.—A lean-to greenhouse.—I have a lean-to greenhouse, being five feet 11 inches long, 4 feet 3 inches wide, 8 feet 6 inches to highest eaves. It is heated with a flue. Bad times prevent my keeping a regular man-servant, and I cannot attend to a fire myself. What I want to do is to keep heating-out plants alive during the winter. Will someone with experience kindly say if a petroleum-heating apparatus, would answer the purpose?—ESSEX RECTOR.

4083.—Plants in pots and boxes.—Having grown a few plants (Roses, Dahlias, Carnations, and Chrysanthemums) in pots and boxes, I shall be much obliged if anyone will kindly tell me the best thing to do with the soil, so that they may be ready for use in the spring. I will sell this year, as I asked a gardener and he told me that the same soil would not be any good to grow them in again; but as I do not want to get a fresh bit I shall be glad to have advice? I have got no convenience for gardening, only a back yard, which gets the sun till two o'clock, and an empty room to keep them in through the winter, and in which I have got my Chrysanthemums well out in bloom, and also three Roses out.—J. BARRY.

4084.—Temperature for a greenhouse.—In my greenhouse I have "Geraniums" and Coleuses, with Rhubarb forcing under the shelves. Will someone please tell me the average temperature at which to keep it to suit the above? It is heated with a "Tortoise" slow-combustion stove, size 1, capable of heating 1,900 cubic feet, as the cubic contents of my greenhouse do not exceed 400 feet. The heat during the night sometimes runs up to 50 degs. Is this injurious to the flowers, &c.? Are there any means without ventilating by which I could keep it cooler? Would a bucket of water stood on the stove be any good, or would the steam arising therefrom be more injurious than the heat?—J. FORSTER, Westbrook.

4085.—An amateur Chrysanthemum grower.—I should be extremely obliged if someone would answer me through your journal the proper definition of an amateur Chrysanthemum grower? I am a member of an amateur society, but cannot agree with a good many of their ways; in fact, I find I cannot afford to compete with with a good many of the members for the prizes offered. At our show this month (at the close) I saw things which I have never seen done by any amateur—members going round the room saying, "Who will buy my last three blooms for threepence?" or, "Who will give me sixpence for a bunch?" shouting at the same time that "These look first prize" or "These look second prize." Of course, it may be all right in gardening, but in anything else the amateur is not allowed to do anything for money in connection with whatever he follows up as an amateur. I know that a good many of our members grow for sale; not only that, but it seems very paltry for a man to show a group of Chrysanthemums, and then, just before the close of the show, to chop off all the blooms and sell them. I should be much obliged if someone would give me an answer to this, as I wish to lay it before our society, and I know it is a thing that is very much abused?—BOY.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

4086.—Single Chrysanthemum (M. E.).—These are very pretty, but I cannot think that they will supersede the beautiful Japanese forms which were to be seen recently at the Aquarium, at Kingston, and other places.—J. J.

4087.—Planting Ranunculus (T. Shelton).—The best time for planting these is about the end of February, then you will have escaped the trying wintry weather; but should the weather not have broken then defer it a little longer.—O. J.

4088.—Oncidium grande (B. H.).—If your plants are not showing any spikes now you may depend upon it you will not have any more this year. You may help them by keeping them in the temperature you name and nearly dry, so that they may break strong and well in the coming spring.—M. B.

4089.—Oatleya labiata (B. H.).—This plant should not have stood still as to describe it as doing. You may assist it with a little more warmth; 55 degs. is rather low for this plant just yet—by this I mean the time when your queries were put into my hands. It may answer very well for a month after blooming if the growth has not started.—M. B.

4090.—Dendrobium Phalaenopsis.—H. H. sends me flowers of this species, which, although very beautiful, are, I think, but the typical form of the plant. They are never large enough, nor have they colour enough for the variety Schroderianum. I do not think this plant is found in North Australia, although I know we are told that is the fact.—M. B.

4091.—Planting Apple orchards (Surrey).—I should advise you to get the ground ready and plant this month some time. If you are resident in the County of Surrey you should have read the address given by Mr. Smees Gardiner upon this subject lately; but perhaps you both heard him and read it afterwards. I am glad so much attention is being paid to Apple-culture in the County of Surrey.—J. J.

4092.—American Cowslip (A. Nutt).—These are the varieties of Hedeclatums. They are beautiful hardy plants, which should be a great deal more frequently grown than is the case. The best soil for them is good loam and peat, with a cool situation. You cannot do wrong in planting these, for if you grow nothing but varieties of the common D. Media they are all beautiful in the extreme.—J. J.

4093.—Sunflowers harvesting.—T. J. M. writes complaining that something has eaten all his Sunflower-seeds, and save him right say I, because if left out till the middle of October he ought not to have expected anything else. I was taught to cut the heads as soon as the seeds were turning black in the outside rows, and then we used every fine day to sun-dry, and then to dry and ripen, securing them from the birds.—J. J.

4094.—Lælia autumnalis (B. H.).—If your plants are not showing spikes of bloom by this time you need not expect them to do so; and you must keep them tolerably dry until the spring, when they may be set growing again. I cannot understand why the bulbs have not sent up any flower-spikes, because it is generally a free-flowering plant; but perhaps they are not strong enough to do so, and you are expending too much on them.—M. B.

4095.—Oatleya bicolor.—J. Ashken sends some flowers of this species; they are good fine coloured varieties. You may name any. 2, Oatleya Menziesiana having a good white ray to round the lip, which gives it the distinguishing character, the sepals and petals being of a bronzy-green. You should not let this plant suffer for want of water at any season of the year, for its thin stem-like bulbs, when once allowed to shrivel, are very difficult to bring round again.—M. B.

4096.—Odontoglossum (H. Piek).—I really cannot repeat what I have so recently said about potting these plants. If you are not a new subscriber you should have seen your question answered a few weeks ago. Perhaps you were on your holiday then and did not trouble to look back when it came home. If this was the case I would ask you to refer to the weeks when you were away, and if not in their search carefully through the mouths of October and September, where I think you will find it.—M. B.

4097.—Traveller's tree (J. B.).—This is a member of the Musaceæ, and is a native of Madagascar. It is sometimes called Urania speciosa, and at others Ravenala madagascariensis. It has large, two-ranked leaves, which are sheathing at the base, and it is this which gives rise to the vernacular name used by you, as the base of the leaf contains a quantity of a pure, cool water, with which the weary traveller may refresh himself. It is only fit for large and roomy stores, as the plants grow to a great size.—J. J.

4098.—Rosemary.—D. W. sends a sprig for a name; but in the shape of oil it was a plant to be found in nearly every garden, and it was one of my grandmother's special favourites. Its name is Rosmarinus officinalis, and it is strange how close the Continental people approach in its name; thus the German calls it Rosmarin, whilst the Italians say Rosmarino, and the French Rosmarin. The best and quickest way to get this plant is from seeds sown in spring, and do not forget to have plenty of it in your garden.—J. J.

4099.—Oncidium tigrinum (B. H.).—This plant now showing flower should be kept in the Cattleya-house. I saw some in full bloom a month ago in this situation, and the scent which they gave off was delightful. But unless these were wanted for a particular purpose they were put into the warmth too soon; when placed in the warmth from the collihouse they should have a fair amount of water, and this should continue after the flowering season. In the spring I like to remove the plant into the cold-house. It is really a very fine and gratefully-performed plant, worthy of everyone's attention.—M. B.

5000.—Lycaste costata (J. Shaw).—This is a plant which has laboured under a good deal of misunderstanding and confusion. Even Sir William Hooker figured the plant, calling it L. Barringtonia grandiflora. It is a very small size in its growth. The flowers, however, are very

much inferior in size to the well-known L. Skinner, being not more than about 4 inches across, whilst those of the last named plant have broader sepals, and these frequently measure double that size. L. costata's flowers are wholly of a ivory-white, saving a faint tinge of yellow in the lip, which is fringed at the sides; it is fragrant after dark. This is your plant, and you will do well to keep it quite cool along with the Oncoglossum. Your potting material will answer thoroughly.—M. B.

5001.—Cymbidium Lowianum (J. Hedden).—This plant should be kept cool, not cold, and, if it comes enough to flower, watch should be kept on it, for during the present month, or the next at latest, the spikes will begin to show, when the plant should be treated to a little more head and water. The flowers on these spikes will not have grown, and be ready for opening until about the month of February or the beginning of March, when they will flower and continue in beauty for two or three months, if they are shaded from the hot and scorching sun, and not allowed to stand in too moist an atmosphere; but you need not anticipate the plant to do the same next year. About every second year is often enough to expect such great displays from the same plant.—M. B.

5002.—Lycaste falling and becoming spotted.—B. Hatfield is much worried about his "Lycaste," and well he may be. He says—"They are going in large running sores." Well, what have you been giving them, "G. H. P."? You do not say; but in spite of your silence on this subject I must say what I think—that you have been for a long time giving them liquid-manure. I do not mean to accuse you of giving this in too heavy doses, but your plants appear to be breaking up and rotting in the next season, and I can really give you no cure. I should say that you will, in all probability, lose your plants; but you may take them out of the pots, cut all their roots off, and let them dry for a time. The truth will be best known to yourself, and if what I say is right you will do well to let liquid-manure feed alone.—M. B.

5003.—Phalaenopsis amabilis.—J. P. sends me a flower of this plant for a name, saying it has ten more of its beautiful flowers on the spike. Well, I give the name under which I have known and grown it for years, and out of compliment to its first introducers and flowerers, which was Hugh Cuming, who sent the plant to the Messrs. Hollis, of Tooting, in Surrey, and also flowers I have seen them do after a long course of such treatment, and I can really give you no cure. I should say that you will, in all probability, lose your plants; but you may take them out of the pots, cut all their roots off, and let them dry for a time. The truth will be best known to yourself, and if what I say is right you will do well to let liquid-manure feed alone.—M. B.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Troubleshooting.—Apply to any good nurseryman.—W. Pinks.—We know of no book to help you. Send queries here.—H. S. B.—It is the fruit of the Potato, and not a Tomato.—J. P.—Apply to the makers of the boiler.—L. S. Hatfield.—We know of no such book.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W. C.

Names of plants.—North Lancashire.—Yes; the old "Cottage Pink" Chrysanthemum.—Scotty.—Linaria reticulata.—Mrs. Battersby.—1, Pernettya mucronata; 2, Specimen insufficient.—J. C. P.—1, Ailanthum grandifolium; 2, Ophiopogon Japonicus variegatum; 3, Cyperus alternifolius; 4, Ailanthum cuneatum; 5, Probably a Zephyranthes; 6, Pileodium aureum.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W. C.

Name of fruit.—Essex Rector.—Apples: 1, Blewitt Orange; 2, Worcester Pearmain, most probably; 3, A finely coloured fruit of Yorkshire Beauty; 4, Seck no further. Pears: 1, Napoleon; 2, Autumn Crassane; 3, Beurré du Capitaine. The Pears were poor specimens.—Lockwood.—Apple Yorkshire Beauty.—W. H. Woodcock.—Apple Royal Russet.—Sylvia.—Pears: 1, Beurré d'Ardenburg; 2, Winter Nellis; 3, Not recognised. Apples: 4, Carlisle Codlin; 5, Leek; 6, Pippin; 6, Hawthornden.

BEES.

4828.—Management of Bees.—The adding of the two stocks of driven Bees last autumn would doubtless make the hive very strong, if done with care. When uniting is done judiciously, and the Bees settle down in peace, a strong hive is the result. But where this work is not properly done failure is too common, and the lives of hundred of Bees are sacrificed. Various causes may make a stock of Bees divide, sometimes an old queen worn out with her duties. Four brood again might cause

dwindling; this is almost certainly disease, known by the caps of the cells being smoky and perforated. The grubs rot in the cells, and have a foul smell. Parasites on Bees are very common in warm countries, and are brought into this country by importing foreign queens, commonly called the Bee-house, and is as large as a small flea, and lives by sucking the poor Bee. Our climate, say rule, does not suit them, and probably as the cold weather comes on they will disappear. Try a little sulphur about the size of a small nut on the floor-board, and put about 4 inches thick of Bruken-fronds on the top of the quilt; let the quilt be porous. Insects, as a rule, dislike Bruken-fronds. Try this; if it does not do any good, ask again, when a more drastic measure will be given. Never use a hive with fixed frames; always have the frames movable, and easy to manipulate. I trust you will have better luck. We have had a good season in East Yorkshire. I hope, Mr. Editor, we shall have some good articles on Bee-keeping this winter. Many Bee-keepers might give their experience of the past season.—GIRGEE.

NEW PHOTOGRAPHIC COMPETITION FOR 1893

Owing to the early date at which our prizes were announced to be sent in this year there was not time to properly take many kinds of outdoor fruits, flowers, and vegetables; therefore we offer further prizes for those things, to be competed for during the present year; allowing till the end of November for the work.

Class I.—FLOWERING PLANTS.—A prize of FIVE GUINEAS to the sender of the best collection of photographs of flowering plants grown in the open air or under glass. This series may include flowering trees and shrubs of all sorts.

Class II.—BEST FRUITED FRUITS.—A prize of FIVE GUINEAS for the best collection of photographs of any of our good garden fruits: Grapes, Peaches, Apples, Pears, Plums, or any other fruit grown in Britain. Fruits should not be provided in dishes if good and clear photographs are sought.

Class III.—BEST VEGETABLES.—A prize of FIVE GUINEAS for the best collection of photographs of best garden vegetables. The object of this is to get fair representations of the finest garden vegetables under the old genuine names. We do not want to exclude real novelties when they are such. In all cases the name of the variety should be written on the back of the photograph.

Class IV.—AUTUMN FLOWERS AND LEAVES.—A prize of FIVE GUINEAS will be given for the best series of photographs of autumn flowers and leaves in the house in a neat style for vase, table, or other kind of indoor decoration.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with paths run on them. Backgrounds should be plain, so as not to come into competition with the subject flowers. Pictures of men or women, hiccups, water-pipes, rakes, hoes, rollers, and other implements, iron railings, wires, or iron supports of any kind, labels, and all like objects should be omitted. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. The photographs should not be less in size than 5 inches by 3 inches. The following are the rules to be observed by all competitors:—

In any of the departments, if no collection of sufficient merit be sent in, no prize will be awarded. All competitors not winning a prize will for each photograph chosen receive the sum of half-a-guinea.

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the names whence they are obtained must be stated, and those sent the copy right of which is open to question. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly; but those on albumenized paper are preferred for engraving.

SECOND.—The name and address of the sender, together with the name and description of the objects shown, should be plainly written in ink on the back of each photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C., and the class for which the photographs are intended should be marked in the parcel, which must also be labelled "Photographic Competition." All competitors sending their photographs returned, if not successful, must enclose postage stamps of sufficient value for their postage.

GREENHOUSES.

AMATEUR.—Span-roof, made of well-seasoned red deal in a strong, substantial manner in sections, and can be put together by any handy man or gardener in a very short time. Complete with ventilators, frame for opening, door with lock, stages for plants, all glass fitted and marked to proper places. 7 ft. 6 in. x 14 ft., 3 by 6 ft., 24 ft. 12 by 3 ft., 25 ft. 12 by 10 ft., 21 ft. 10 in. Lean-to's from 4 ft. Strong Garden Lights, 3 inches thick, painted and glazed, 4 by 3 ft., 6 in. each; 6 by 4 ft., 8 in. each. All securely packed on rail. For illustrations of above and price of other sizes, send for Complete Catalogue, just free. Estimates free for every description of horticultural work.

J. JAMES,

355, High-road, Chiswick, London.

STOVES

TERRA-COTTA—PORTABLE—FOR COAL.

GREENHOUSES heated 24 HOURS for about ONE PENNY without attention. IMPROVED PATENT PORTABLE TERRA-COTTA STOVES for COAL give pure and ample heat with common coal, in coal and coke. For GREENHOUSES, BATHROOMS, &c. Pamphlets, Drawings, and authentic Testimonials sent. See in use at Patentee's T. ROBERTS, 34, Victoria-st., Westminster.

GREENHOUSES! GREENHOUSES!

All intending purchasers should call or send to the Royal Arch Horticultural Works, Bradford. The principal builders to all the Nobility, Gentry, and Nurserymen in Yorkshire and surrounding districts. The best and cheapest makers in the Kingdom. Catalogue, post free. Two Stamps. W. ANDREWS & CO., Fifehead, Bradford.

"FRIGI DOMO" CANVAS.

Much of Prepared Hair and Wool, a perfect protection to all Plants, Blooms. Cheaper than any kind of mat, and will last for years. To be had from all Nurserymen and Gardeners.

BENJAMIN EDGINGTON
2 DUKE ST. LONDON BRIDGE

BUTCH BULBS.—Great miscellaneous Sales.—EVERY DAY, 5,000 lots and weekly.

MESSRS. PROTHOROUGH AND MORRIS will SELL BY AUCTION at their Central Sale Rooms, 67 and 68, Chancery-lane, London, E.C., EVERY DAY at 12 o'clock, large quantities of first-class Hyacinths, Tulips, Crocus, Narcissus, and other bulbs from Holland, several of the best also Roman Hyacinths and other French Bulbs. Commission accepted. Lots packed and forwarded to all parts of the Kingdom. Shippers resident in stamps to the Auctioneers will ensure a supply of Catalogue for 12 consecutive Sales. 8 in. x 11 in. Sales of Plants in pots every Monday and Thursday; Orchids every Friday.

SPLENDID BULBS FROM HOLLAND. SALES EVERY MONDAY, WEDNESDAY, THURSDAY, AND FREQUENTLY ON SATURDAY. IN LARGE AND SMALL LOTS TO SUIT ALL.

MR. J. C. STEVENS will SELL BY AUCTION at his great rooms, 35, King-street, Covent-garden, the following quantities of choice HYACINTHS, TULIPS, GIGEOIDS, NARCISSUS, and other bulbs, arriving daily from well-known firms in Holland in the finest possible condition. In view of the number of bids, and Catalogue had free of application. N.B. SHIP BUT BULK AND RELIABLE BULBS will be offered.

BECKENHAM, KENT.—To be Sold privately. A DETACHED HOUSE RESIDENCE, suitable for a modernized family; situated on high ground, overlooking on one side an extensive park, walled with lime and timber, and on the other commanding fine views in the direction of Forest-hill and Sydenham. The grounds, of about 12 acres, are well laid out and planted with choice trees and shrubs. The furniture is large, and the kitchen garden productive and well stocked with fruit-trees. The house is substantially built, the reception room lofty and well proportioned, with convenient domestic offices on ground floor. There are on the ground floor seven bedrooms, reading room, bath-room, &c. (good stabling for three horses, coach-house, poultry-house (with run), gardener's tool-shed, &c., &c. The property is held for a term of about 70 years, in a nominal ground rent of 24 lbs. per annum.—Particulars from A. M., care Editor, 37, Southampton-street, W.C.

A GENTLEMAN recommends a good outdoor garden for a small place, who knows Roses, Carnations, and hardy flowers well, and ways of arranging them; also good kitchen garden; active man; married; no children; disengaged at end of year.—Address "H. B. P." in index titles, 37, Southampton-street, Strand, W.C.

WANTED.—The neighborhood of Fitzjohn's Avenue, a SMALL FURGE OF LAMB in insect GLASSHOUSE for purpose of FROST-PROOFING. Apply by letter only—C. WOOD, a SON, 21, High-street, Marylebone.

RAFFIA for Garden Tying.—Best quality; 10 cash with order; carriage paid. 1 lb. 9s. 1 1/2 lb. 1s. 4d.; 3 lb. 2s.; 7 lb. 4s. 6d.—CLIFFORD, 25, Bank-st., Milestone.

BRASS WIRE HYACINTH SUPPORTS, made of flat wire, best quality, 2s. 6d. per doz., carriage paid on 1 dozen and upwards.—E. FROGIN & CO., Tynes Wireworks, High Road, Newcastle-on-Tyne.

BEE-HIVES.—Catalogue of improved live and price-free.—H. B. NEIGHBOUR & SONS, 127, High Holborn, W.C. Established 1815. N.B.—Vine Co., Neighboer & Sons, Advt. in GARDENING, April to July.

"THE GARDEN GUN."—Fires bullets, shot, or darts. Kills birds, rabbits, &c. No powder or noise required. Price, 2s. 3d.; extra post. No carriage paid. From inventor—JOHN BULLOCK, Naturalist, Sunderland.

JONES & ATTWOOD.

IRONFOUNDERS, STOURBRIDGE.

Supplied with various arrangements of Pipes. For Greenhouses, &c. Catalogue free. Jones' Treatise, "Heating by Hot-water," 120 Pages, 50 engravings. Cloth, 2s.

HEATING APPARATUS, From £4 4s. and upwards.

Full Particulars and Local Agent's Address from R. JENKINS & CO., ROTHERHAM.

SILVER MEDAL HORSE-SHOE BOILER

Section of Boiler and Pipes showing method of hot blast and Automatic Regulation, awarded the SILVER MEDAL (at MELBOURNE) by the N. E. Society in 1883; still stands without rival for POWER, EFFICIENCY, and ECONOMY. C. P. KINNELL & CO. hold one of the LARGEST STOCKS of hot-water appliances IN THE COUNTRY, including every Boiler of known merit and excellence. New Illustrated Catalogue containing guides to amateurs on the hot-water apparatus (free on application).

CHAS. P. KINNELL & CO., IRONFOUNDERS AND BOILER MANUFACTURERS, 65, Southwark Street, London, S.E.

NO FLUE REQUIRED. (SAC'S PATENT.)

8 feet over all. Improved Condensing Greenhouse Heater, for Gas, 35s.; for Oil, 41s. THE LAMP MANUFACTURING CO., 12 and 14, Leonard-street, City-road. AGENTS: HENNING & CO., Chancery-lane, and all Ironmongers throughout the Kingdom. Write for Prospectus.

GLASS

FREE ON RAIL IN LONDON, packages included.

The following is a List of sizes always in stock:— 10 by 8, 12 by 9, 12 by 10, 14 by 10, 16 by 12, 20 by 12, 20 by 13, 13 by 11, 14 by 12, 17 by 13, 20 by 18, 24 by 18, 24 by 16, 20 by 14. Glass put in any size at a slight advance on the above prices. Glass is cut and packed in own warehouse by experienced men, therefore quality of glass and packing is guaranteed. All glass is put on mill free of charge, and guaranteed to be in normal condition. Price, 4d. per lb.; Putty, 1d. per lb. Please apply for prices for large quantities, when special Original Patent will return post, mentioning this paper. J. B. ROBINSON, 31, Moor-lane, Cripplegate, London, E.C.

HARDY PLANTS IN POTS.

MANY kinds of hardy plants, such as Auriculas, Ferns, &c., are grown in pots, and at this time of year it is a debatable point with many as to whether they need any protection or not? It is quite true that the same varieties in the open ground do not get, or appear to need, any protection other than that supplied by Nature; but plants in pots are in a very different position to plants rooted in the soil, which get considerable protection to their roots by striking down deep into the earth, while those in pots get frozen right through with one night's frost, and are encased in ice as long as the frost lasts. For this reason I always place all hardy plants in pots in cold frames, or else bury them in coal-ashes or leaves, packing them closely together, and shaking litter over them if the frost proves very severe. Strawberries, when grown in pots, are often ruined by being fully exposed to the action of frost, to say nothing of the breakage of pots it entails, and if cold frames or cold-houses are not available, plunging is absolutely necessary. It is not advisable to let any kind of hardy plant get dry at the roots, for it is unnatural and harmful, the roots being more or less active all the year round; but they should not be over-watered, as the drying process is very slow when the pots are excluded from the atmosphere, and if watered when packed away may be safely left for a month, and as they only need protection of glass in severe weather I pull the lights right off in mild, showery weather, which saves watering at the same time. Coal-ashes, Cocoa-nut-fibre, and leaves are excellent protectors, but, failing these, the pots may be plunged to the rim in garden soil.

J. G., *Hants.*

HERBACEOUS CLEMATIS.

CLEMATIS DAVIDIANA, of which a cut appears in GARDENING, Oct. 28, page 479, is not as much cultivated as it deserves to be, nor is it as tender as generally, but erroneously, regarded. It is a special favourite of mine, and both in the South and East of England I have found it quite hardy without the slightest protection when planted close against the foot of a wall. The note that accompanies the cut above referred to quite understates its merits. From the time the shoots appear above ground in spring its leafage attracts notice. The flowers appear in July, but they last for quite two months. They resemble Hyacinth bells, are of a lovely shade of pale-blue, and are clustered together very thickly, opening in long succession. Last, but far from least, they have a delicate and delicious fragrance. Its scent was even noticed in the rooms of a house where a fine plant grew and flowered in one of the terrace borders under the window. This brings me to the suggestion I want to make, and that is the value of this and other herbaceous Clematis for permanently beautifying window borders or beds such as are often seen under windows close against the walls of the house. In such places no fear need be entertained as to the hardiness of this Clematis over the greater part of England,

and even the trauken of covering the crown with ashes or Bracken is a mere detail that none would grudge performing if they had once seen and enjoyed the beauty of this species. I often see such borders as I have above alluded to filled with the poor, feeble, tender things that have no associations, no fragrance, and do not appeal to cultured or refined tastes. It is infinitely better to have plants of fine character, permanent endurance, and fragrant with sweet odours, clustering at the base of the house, loading the air with sweetness, and one of the best of these is Clematis Davidiana. Then there is another fine herbaceous species, the Bell-flowered Clematis (*C. campaniflora*), an old plant introduced from Portugal early in the present century, but now so neglected that I do not know where it can be obtained. It is a truly lovely species, perfectly hardy, with large bell-shaped purplish-white flowers, *C. recta*, also called *crecta*, in consequence of its erect habit, is another interesting species. It grows about a yard high, has simple pinnate leaves, and bears dense clusters of white, sweet-scented flowers. *C. integrifolia* is another kind worth rescuing from comparative obscurity. It has large, entire, oval-shaped, smooth green leaves, grows about 2 feet high, and has lino flowers, the petals quite thick and fleshy. Lastly, there is *C. tubulosa*, which is very like *C. Davidiana* in flower, but differs somewhat in its leafage. Both are natives of China, *tubulosa* having been introduced in 1845, and *Davidiana* nearly twenty years later. These things, associated with hardy Fuchsias, Sweet Verbenas, Myrtles where they thrive, Lavender, Rosemary, Balm of Gilead, &c., would adorn window-borders in a delightful way, and with spring bulbs among them keep them gay and sweet for the greater part of the year, being away with the necessity of annual planting, from which only tolerable results are obtained. A. H.

4886.—**Primula obconica**.—This plant is certainly dangerous to grow unless you know that all who are likely to come into contact with it will not suffer from doing so. To many, or perhaps most persons, this plant is perfectly harmless, but to others merely touching it causes an acute attack of Nettle-rash or eczema, with considerable redness of the skin and intense itching. Unlike the stinging of a Nettle, which is apparent at the moment of contact, the unpleasant effects caused by touching this Primula are not felt until some time afterwards, and then instead of subsiding in the course of a few hours, may remain for some days. Many persons have been made quite ill by frequently handling this plant, and not being aware of its obnoxious property. Its poisonous qualities no doubt exist in the glands at the base of the hairs on the leaves and flower-stems, which, like those of the Stinging Nettle, contain a poisonous fluid. *Primula obconica* is a plant which is well worth growing were it not for this very undesirable trait in its character.—G. S. S.

4977.—**Vegetable manure**.—"I. B." has got one of the most useful composts for the herbaceous border he could possibly have. It will cure every subject which needs a mulch, and

cannot be applied at a better time than the present. Such subjects as Delphiniums, Phloxes, Aconites japonica, *Michauxias*, Daisies, Ranunculus, &c., will all thrive under such treatment. I would advise that hoists over the crowns of his plants with a little fresh lino before applying the soil. This will kill slugs that may be present, and can harm none of the herbaceous plants. If the beds are dressed now a considerable amount of protection will be afforded, while the winter frost will improve the soil and be kept from harming the plants at the same time.—L. U.

—If the material you refer to is that from vegetables only, you cannot have a better stimulant for your herbaceous beds; but if it is composed of the refuse of the garden generally, including weeds in a seedling state, you will regret using it for that purpose, as you will be sure to get a plentiful crop of weeds from it next year. When I do not clear the rubbish of the garden, I always use it amongst the vegetable crops where the hoe will not do any damage when cutting up the weeds as they appear. Of course, it is well ratted before being used.—J. C. C.

—This should be a good compost for herbaceous borders or any other purpose, and might be used at once.—E. H.

4928.—**Sulphate of ammonia**.—I have found this a very useful manure for Chrysanthemums. Under the following treatment I have been very successful with these beautiful flowers this season. When potted off into flowering pots, I fed them twice weekly with soft-water, not too strong, keeping them well watered all through the summer. When buds began to form I changed the food, and gave a large teaspoonful of Ichaboe guano to each pot once a week, watering well over this; then when buds showed signs of opening, I dissolved a large tablespoonful of sulphate of ammonia in 4 gallons of water, and gave the plants a thorough good watering with this fluid once a week; this improves size and colour of blooms. Do not give alone too often, as it is very strong and might spoil the plants. With plenty of sun to ripen the wood, and careful fanning of the above, anyone may grow Chrysanthemums which will be a credit to themselves and the delight of all who see them. My Chrysanthemum-house is almost on, and is quite visible from the street, and hundreds of people daily stop to admire the beautiful show of these flowers.—LANSUDDERY.

4967.—**Worms on a tennis-lawn**.—Perhaps the ground is very badly drained, and, if so, now is the time to rectify such mistakes. You might apply, however, a dressing composed of, say, 5 lb. of newly-slaked lime to 15 gallons of water. This must be well stirred frequently, and allowed to remain until it gets quite clear. Carefully draw it off, leaving the sediment remaining, and apply with a rused watering-pot over the surface of the lawn. A damp day should be chosen—not, of course, in frosty weather. It is very easy to sweep up the worms when they come to the surface.—C. T.

Tulip Pictée.—This is a beautiful variety. The flowers are of a magnificent with rose, a most brilliant and pretty colour. It is not stiff, and may be used for decorations.—E. O.

GARDEN WORK.

Conservatory.

The Chrysanthemum shows are now over—so far, at least, as public competitions are concerned; and judging from the character of the seedlings which are in the possession of Mr. Jones, of the Kite Croft Nursery, and others, we are destined to have still larger blooms in the future than we have at present. How far this will go it is impossible yet to say, but it is absolutely necessary—for exhibitors, at any rate—to buy the big flowered varieties if they are to keep in the front rank. The tendency is to give in smaller pots, resting on good soil, firm potting, and judicious feeding to enable the plants to carry a couple of fine blooms to perfection. These dark, sturdy plants, curving, say, from two to four blooms, are more useful to the small grower, who cannot build lofty houses, than tall plants which he cannot protect. With this question intimately connected the right time for taking the cuttings. Many good growers act on this simple principle of taking a good cutting when they could get it, any time between the 1st of December and February, and still carrying out the same principle when the plants are cut down in May or June. The strongest cuttings are selected and converted into strong, sturdy plants, which, if permitted only to carry one bloom, will grow to a larger size, and be valuable for grouping in the conservatory, or to move into the rooms. The monster plants, 3 feet or 2 feet in height, are of much use for decorative work. There is a good deal to be done and learnt about the Chrysanthemum and its culture yet. We are now having a spell of whitey weather, and the temperature in glass-houses may be dropped a little below the customary degree, as in stormy weather very little air can be given. If the thermometer in the conservatory does not fall below 46 degs. in the morning no harm will be done. See that the heating apparatus—boilers, flues, and everything relating thereto—is kept in a perfectly clean condition. It is a good plan to let the fire go out occasionally to give the apparatus a good sweeping out; fuel is often wasted by not keeping flues, etc., clean. Another matter that requires careful attention is when the boiler and flues are cleaned, well is the size of the flues round the boiler. When the flues are small the heating power is reduced, and there is more danger of leaks, especially at the back of the boiler, getting choked. No boiler flue should be less than 4 inches wide if the fuel is produced in the heat it contains. I need hardly say be careful in the use of the water-pot now; damp destroys many flowers. And in sweeping flues, etc., avoid raising a dust. Camellias are turning out first-class flowers, but they are not popular now; they are too stiff, and are lacking in perfume. Tea Roses should be moving now.

Unheated Greenhouse.

The owners of cold houses have had a long period of enjoyment. A warm summer, followed by a mild, open autumn, has rendered the absence of fire-heat of little moment; but sterner times are coming, and it will be necessary to make things as snug as possible, if possible, of course, to be uncrucious. I had a cold house full of Chrysanthemums; judging from the character of the weather I looked for a severe frost, but an unobtrusive intervention of a milder weather took kindly to the plants. Well, the frost was not so severe as I anticipated, and my labour was to a great extent lost; a covering over the roof would have made all comfortable. I have great faith in roof-covering on all glass-houses where it can be carried out; in forcing-houses it not only economises fuel, but the internal atmosphere is more genial; but this covering when boring is going on should not be left on longer than is necessary. With a perfectly cold house the cover may remain on longer without doing injury. I have had cold houses and pits covered up for a week, and no harm followed, but the uncovering was gradual. Plants after being for some time in a bad light will not bear full light all at once. If covers cannot be used, see that the pots are all deeply plunged in some non-conducting material, such as cheap Coarctum-fibre sawdust, the former preferred. Of course, no water should be used in the house during a severe frost. My rhos and other plants will, perfectly hardy should have their branches from the water, and in the case of the Camellias (Frigidulosa), or something to protect from a low temperature. Dracenas, and the green-leaved varieties, may be wintered safely in this way.

Stove.

There will be a grand display of Polistes now. A group of P. tuberosa, with a few plants of the white variety that I raised last year, will have a good effect. Among the effective plants which are always more or less in flower may be named *Hedyselin speciosa major*; this is a very useful old plant, still found in most good collections of stove plants. *Ephiphyllym* when well done are a lust in the vesicles, but though often grown in a stove the flowers will last longer if the plants are taken to a cooler house. They may be grown in baskets, and I remember seeing the back wall of a small stove covered with different varieties by grafting on to one of the plants of the fast-growing varieties. The grafting is a simple business; just make an incision in a prominent spot of a *Cactus* stem, not too old. Press a shoot of *Ephiphyllym* and thrust it into the cut, fixing it with a spur from the *Cactus*, and in a short time the union will be complete. *Ephiphyllym* will root just as easily from cuttings, but plants from cuttings are apt to damp off at the collar if not carefully managed. Threesprinkled cuttings have a surety effect in the stove now; the light-red flowers are numerously borne on long, three-like stems, which give the plants a very nice appearance when in bloom in winter. They are ready propagated from stout cuttings in spring, and spring-druck plants will flower following winter.

Ferns under Glass.

These are always attractive, and a free use can be made of the best kinds in the conservatory to give character and tone to the flowers. Everything is quiet now in the fernery under glass. There is nothing at present requiring potting, but the winter will see a little about placing in a stack of potting-soil for those and other plants. There is less peat and more loam used for Ferns

than there used to, and where good loam can be obtained very little peat or leaf-mould need be used for the hardier kinds of Ferns, whether greenhouse or stove species. There is considerable advantage in potting Ferns firmly; growth is denser and the colours greener, and larger plants can be grown in pots of limited size.

Cold Frames.

Tender plants are kept in cold frames, warm, dry coverings will be necessary in sufficient bulk to keep out frost. The treatment of the past few weeks will have led up to this. Little water has been given, and the plants having been kept dry, and, if covered heavily with dry litter (Ferns or Rindus will do), the frost will not do much harm; but the sides of frames must have a bank of litter placed against them, or the frost if severe will penetrate there.

Window Gardening.

Keep all plants free from excitement as possible. Growth made during short days, especially in severe weather, will be of but little use to the plant. Little or no water will be required during cold weather, but the sides may be sprayed occasionally. All the tender plants must be moved from the windows at night to some position in the centre of the room, where a covering of newspapers may be placed over them.

Outdoor Garden.

Hurry on the planting of deciduous trees as fast as possible. The ground is in good condition for the work. In some of my planting operations lately I was surprised to find the ground in some places still quite dry, though since the break-up of the drought a good deal of rain has fallen. I think it is a good plan to give a good watering to all trees just before the work is quite finished. My usual plan is to fill them nearly level, treading in well, and then give one or two inches of water, according to the state of them, the object being to raise the roots well in the land, and when the water has drained away, say next day, flush filling in the hole, and finish with some non-conducting material; or if this is not available, raise the soil rather higher than customary over the roots, the surplus soil to be levelled down in the spring. There would be few deaths if something of this kind was done by planters. The best season for planting Trees was long since over. I have planted Roses in spring, but so far as regards hybrid Perpetuals—in fact all those except *Tea*—I would plant in November if possible. In cold districts it may perhaps be advisable to keep them back till the winter is over; but there is not much gained by it if the stems of the newly-planted dwarf Teas are earthed up a little, and the heads of the standards protected with dry Fern. Those, of course, who never lose Tea Roses need not adopt this precaution. A mulch of manure over the roots of newly-planted Roses is always beneficial. Of course, everybody who is planting dwarf Roses covers the stock so that the plants have a chance of making an independent set of roots. Such borders of hills with old leaf-mould and manure.

Fruit Garden.

Do not delay pruning longer than there is power to grapple with the work. The berries are all down, and the work can never be better than now. As much pruning is best till the first of Christmas it has to be hurried over, and is then imperfectly done. The wall trees and espaliers are the most important, as when they get out of hand bringing them back to the wall again involves a good deal of cutting, and the effect is, on the whole, injurious. Of course, when the tree is crowded with useless spurs it is always wise to thin out freely. In gardens where the gooseberry-culture has been troublesome last spring or summer, an effort should be made now to clear out the large fruit-producing and succulent from around the bushes, and putting it in a trench in some other part of the garden. If these bushes at this season are buried a foot deep in the ground they will never work through. After the earth has been removed some fresh lime should be watered under the bushes, and, if necessary, a little manure may be given, and soil from another part of the land brought to make things level. Bush fruits as a rule do not get manure enough; year after year they bear heavy crops, and die to decay. The soil, if it is given them. Cuttings of bush fruits may be planted now. Select stout straight cuttings from 12 inches to 16 inches long. Cut close to a joint at the bottom, and remove all the limbs from the stems except the two upper ones. Plant in rows 1 foot apart, and 6 inches apart in the rows. Plant 3 inches deep, and tread the soil firmly about them. A little old leaf-mould or hot-bed manure scattered between the rows will make their rooting a matter of certainty. Well ripened pot Vines may be planted now for the production of early Grapes in a night temperature of 50 degs.

Vegetable Garden.

Protection for tender things is an absolute necessity. Cauliflowers, Winter Broccoli, Lettuces, and Endive, if more than half grown, will perish if exposed to the frost. There are many ways of protecting these and other things. Those who have plenty of soil can use frames, and fill the perishable plants with balls and plant under glass and cover with mats or dry litter when frost sets in. In the absence of glass other means should be adopted. The best way to secure Winter Broccoli and Cauliflowers is to dig them up with balls and plant down in the earth so that most of the stem is buried; they will, in fact, be heeled in, and the best position is a dry bank or raised border, a covering of mats or hessian cloth will do the same thing, or there will keep all safe. Many late Cauliflowers and early Broccoli are lost through not taking proper measures to protect them in good time. Celery is another matter which requires looking closely after. Last year many lost their Celery through frost for want of a little protection. It will be advisable also to take up plenty of Sea-kale for forcing; the crowns, after the strong or long roots are trimmed off, may be laid in on the north side of a wall to ensure perfect rest, and when frost sets in be covered with litter, so as to be able to get the roots up required for forcing. Asparagus to meet early requirements may be treated in a similar manner. The forcing-ground will be in full operation now. Forced products, from Mustard and Cress to French Saladings and Mushrooms, will be in frequent demand now, and the man who can do the most with the least means is the most successful in his calling, and this involves constant thought and watchfulness. Get all vacant ground trenched as soon as possible. This is the first step to good vegetable culture.

Work in the Town Garden.

The shortest day will be upon us almost directly, and, especially after the sharp frosts and severe weather experienced recently, the contents of most town gardens wear a very desolate appearance, with inclosed and outcloses in thickly populated localities everything out-of-doors is so soot and smoke-begrimed that even were there a few flowers still lingering in sheltered nooks they would not be presentable, and even the berries of *Hollies*, *Aucubas*, and others are nearer black than red. When the weather is mild a good watering with a garden engine, hose, or syringe will greatly improve the appearance of evergreen shrubs, at least, of such as, like the *Eucalyptus*, *Arbutus*, and *Rhododendron*, are furnished with smooth and glossy leaves. The leaves of small shrubs of this and others in window-boxes will certainly be greatly improved, both in health and appearance, by an occasional syringing, though it is an extremely tedious job at the best. Inside window plants of the same character, such as *Camellias*, *Dracenas*, *Aspidistras*, *India-rubbers*, &c., should be similarly treated once a week if possible, using tepid water and a bit of soft sponge, with a very little soap if the leaves are very dirty or there are any insects about. Plants in rooms must be very carefully watered at this season. Now that many of the strong fires are the rule more water will be required, on the whole, than when evaporation was less active; but any excess must be carefully avoided, especially in very cold weather. Evergreen subjects ought at all times to be kept in a more moist condition than such as can bear their leaves; and plants in growth, bloom, or both, need more liberal supplies of water still. Much the same rules hold good in the greenhouse, but much depends upon the temperature maintained, if low, water sparingly, and chiefly in the forenoon of mild or bright days; if high, more must be given, and things must not be allowed to get very dry when strong frosts are employed on cold nights. Chinese *Prunus* are the gayest and most useful plants here now, and with these the pretty berried *Solanum* contrast or blend admirably. These last cannot, however, be grown in very windy places, or, rather, though they will grow all right they refuse to "berry" freely, so that *Camellia* and *Prunus* plants must be sought in *Camellias* are good in plants, and I have had them blossom freely every year after year where the soil sometimes was on their leaves so thickly that you might almost scrape it off with a knife. These pretty plants must be kept cool and loved. They will shed their buds unopened. Early-potted Roman *Nyctaginis* will expand very quickly now in a temperature of 60 degs. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a garden diary from December 2nd to December 10th.

Started a house of pot-Vines; the house is a low lean-to, and is fitted with a roller and a canvas blind, and much benefit has been found from the use of this kind of cold nights in frosty seasons. The Vines are strong and well ripened, and are 6 feet long in 12-inch pots. A bed of straw, or a layer of straw, is put under the plants, the house being something used for Cucumbers. The pots are plunged in the leaves, and the ground around arising therefrom is a great help to the plants generally. The Vines are all bent back, and will remain so till the buds show signs of breaking. Very little water will be given for some time, as the roots do next to nothing till the buds start. The night temperature at starting will be about 50 degs. Scarcely any ventilation will be given till the buds are breaking into leaf; but, of course, the house is not air-tight. Should the Vines appear to be breaking well they will not be interfered with till ready for tying up; but if any of the buds appear sluggish and hang fire, the backward Vines will be straightened out and the roots twisted in one direction till the wood cracks right up to the end. This never fails to set the sap in motion. I have applied this treatment to Vines which break badly on many different occasions, and always find it has the desired effect. Planted more French Beans in pots, three in each pot, with the pot-Vines. The pots are all half full of soil, space being left for earthing up when the Beans have grown a few inches. Took advantage of frosty weather to wheel manure on land ready for digging in; the soil of a rather holding character, so no harm will be done by manure now. In the case of a plot of light land shall make the manure into compost with other waste matters, and keep it in a heap till the spring. If light land is manured with decomposed manure a good deal of the strength will be lost, and it will be better to use the manure, putting manure into light, hungry land is something like putting water in a sieve, and does very little good. Finished pruning bush fruits. Dressed the ground with manure and forked it in between the rows of limes. Made up another bed for forcing Asparagus. There is nothing like four-year-old roots which have never been cut from to give good results, and they respond to the heat as soon as required, which is more than old roots always will. Frames full of Lettuces and Endives are closely watched, and I want to make them last as long as possible. Thought a hot-bed has been filled with small plants of the variety Paris Market to come on later. It takes longer to blanch Endive now; but in cases of emergency they are taken to the Mushroom-house, where they are finished off in a few days or less if required earlier. Small saladings, such as Mustard and Cress, are sown often in sets of boxes which are placed in a forcing-house. A two-light frame has been sown with Radishes, and another frame on a gentle hot-bed has been sown with French Horn cress. Knives Potatoes have been started in boxes to fill arched houses, Sharp's Victor and the old Ashpot being the varieties. Thinned out shrubs in a shrubbery that was planted a few years ago, and which has become crowded.

4981.—Growing Clematis.—Train the Clematis on wires—painted wires, not galvanised, are best. 12 feet apart would do. Two good varieties would be Jackman's, purple, and Harry's, white; and these two, planted alternately, and permitted to mingle their blossoms, would look well.—E. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables. The drawings of these drawings so made will be engraved in our magazine, and will appear in due course in our "Gardening" column.

HOUSE & WINDOW GARDENING.

CUT-FLOWERS IN THE HOUSE.

PLANTS are often now grown as much to give cut-flowers for the house as for their effect in the garden. This is a pity in some ways, as borders are spoiled if the things are cut about to fill bowls and vases on the table. Where possible reserve a part of the garden, so as not to interfere with the plants in the more conspicuous positions. Sweet Peas and similar things could well be grown there, and hundreds of bloom

Narcissus calathymus reflexus.

gathered without interfering with the clumps in the borders. A large number of hardy perennials are delightful to cut for the house, and the more simple the arrangement the better. A bowl of Paeonies, German Irises, or a posy of one kind of Carnation are in every way better than any absurd wiring of the blooms or imitations of the fads of professional florists. In the spring the various kinds of Anemone supply lovely masses of bloom, A. fulgens in particular lasting well in water. Lilies of the Valley, Snowdrops, the Lenten Roses (Hellebore), Iris reticulata, Spring Snowflakes, Forget-me-nots, Daffodils, Primroses, Auriculas, Polyanthuses, Tulips, Tufted Pansies, and Ranunculuses all being of use in one form or other of decoration. Some flowers fade quickly when cut, the Lenten Roses (Hellebore) especially, but this may be in part obviated by occasionally dipping them into water, and removing a little of the stem each day. Daffodils are, of course, the most exquisite of flowers for cutting, and when arranged with Mahonia foliage the shades of yellow are intensified. They should always be gathered when about half expanded, and this applies especially also to the German Iris, half-opened buds expanding in fullest beauty in water. When they open in full exposure to the weather they get much sullied by the storms of wind and rain. In the summer months a well-planted garden is full of useful things to cut for the house. Achillea The Pearl and A. mongolica, the former with double pure-white flowers, each like a little rosette, and the latter also white, large, and single, are worth growing for this purpose alone. Anemone japonica alba is perhaps the most useful of all hardy perennials for cutting; it blooms for many weeks, and the flowers last well in water. Then come may all the White Antirrhinums, Michaelmas Daisies in variety, Early Chrysanthemums, particularly Mme. Desgranges, its sports, and the delicate rose-coloured Mme. Grunewald, Coreopsis lanceolata (yellow), Ghidoli, Tufted Pansies, and the Sea Hollies. These are very beautiful, the metallic blue lustre, so to say, on the flower-buds imparting to them distinct beauty. Bryngium plantum, which produces a crowd of small, conical, steel-blue heads, E. giganteum, and E. Olivieranum are all useful, and none difficult to grow in light soil. Whether the decorations are extensive, or the flowers are merely cut for the house, they should be simply arranged. One of the most beautiful arrangements, if such it could be called, I have seen was a bunch of Comtesse de Paris Carnation in a Munstead glass. Another point is to use as far as possible the foliage of the flower with it. In the case of Daffodil this

cannot always be, as the bulbs are injured by the removal of leafage; but Roses, Paeonies, and, in fact, almost everything, are better without Ferns, Asparagns, or stereotypical leafage. Chrysanthemums are, however, of course, best with such leafage as the Mahonia, or even twigs of the Beech-tree. The colours of the flowers, especially if they be chestnut-red or shades of orange, are delightful in association with the autumn leafage of hardy Azaleas, the Liquidambar, or commoner things. The pretty little Narcissus figured is rather choice for cutting, but potsful of the bulbs in flower may be used in many ways.

CHRYSANTHEMUMS FOR A WINDOW.

THESE popular flowers can be grown so well by amateurs without fire-heat that no one who is willing to take a little trouble in watering the plants, &c., through the summer, should now be without a few specimens. The earlier flowering varieties (not those of the Mme. Desgranges type, but Chrysanthemums which flower early in November) should be selected, as they last on a long time into the winter with care, and form such valuable decorations just when other flowers fail us. At the present time, when Chrysanthemum shows are so frequent, it is easy to select the names of a few good types of blossom; but if novelties are needed, the following dozen may be relied upon to give good results: Mrs. Charles Blick, deep golden-yellow, very large flowers, with a satin sheen in its long petals; Lord Brooke, a magnificent incurved Japanese, of a rich bronze shade; Mr. W. H. Atkinson, an immense flower of a bright coral-red, very distinct and handsome; Holborn White, of the purest ivory tint, reflexed Japanese; Mme. Edmond Rey, a soft rose-pink, with creamy white centre, which blooms rather earlier than the rest, and is highly decorative in effect; Vice-President Calvert, deep-crimson, with odd-gold reverse petals, a fine Japanese incurved variety; Mr. C. B. Whitwell, the deepest maroon tint yet introduced, which forms an excellent contrast to the paler shades; Miss Ethel Paul, a very beautiful pure-white bloom, with the central petals incurving; Miss Ruth Cleveland, a delicately shaded pink and silver variety, with remarkably broad petals; W. A. Manda, a blossom that has won the title of the "Yellow Ostrich Plum" on account of its soft, fluffy appendages, which give its petals a feathery effect; Colonel W. B. Smith, deep-orange, shading to terra-cotta, which is specially useful as a vigorous and rather dwarf variety; and Mr. Charles K. Shea, of a pale lemon-yellow, very pure and charming. The above dozen does not contain any of the shades of blue and magenta which are often found in exhibitions. These, though beautiful in themselves, are quite unsuitable for decorative purposes, anything like a magenta tint being quite inadmissible in rooms where good taste prevails.

CRYSANTHUS may now be obtained very cheaply, and can be rooted by placing each firmly in a thumb-pot of sandy soil, then sinking the little pots to the rim in a box of a fine ashes, which should be deep enough to take the cuttings without their being touched by the pieces of glass which should cover the box. The cuttings can be kept damp, but not soaking in water, the ashes also being damped so as to afford them a moist atmosphere. The box may be placed anywhere in a room to which frost does not penetrate, the glass being turned or wiped dry daily. As soon as the cuttings begin to grow (which will be in about six weeks' time, or more if they are put in early in the season), they should be gradually hardened off, giving more air and light daily until they can stand without the glass, without drooping their foliage. They may then be repotted, giving slightly richer soil, and the tops should be pinched off a week later to induce them to form bushy plants. This process of repotting and putting back should be repeated three or four times before the end of June, each time giving the plant richer soil with turf-mould, leaf-mould, soot, and sand until they have reached their flowering pots, which may be 9 inches or 10 inches across the top. They are best out-of-doors after the spring frosts are over, and must be well ripened in the sunshine to do well, morning sun being preferable to that of the afternoon. Regular watering, and the addition of liquid manure or soot-water (made by steep-

up some soot in a piece of coarse sacking, and soaking it in a pan of rain-water, which can be renewed for weeks, and should be used in a clear, thin state) from the end of July till the first flower in showing colour are essential to fine flowers, but after this time pure rain-water only must be used. Disbudding should only be moderately done when Chrysanthemums are for decorative use. Some varieties, however, need more buds removed than others to ensure effective sprays of bloom. When the plants are in bloom they may be placed in a sunny window or a bow-window with impunity, but should not be exposed to the fumes of gas. They should be removed at night if this be turned into a bathroom or spare room, where a piece of linoleum or a large tray can be placed beneath them, and watered over the foliage (but not the flowers), from a roset pot, so as to give them damp, cool air at night. If black-fly should attack them, which it may do if they are kept short of water, or in too dry an atmosphere, the first traces of it must be immediately removed with a bit of sponge and soapy water. If this washing be repeated daily two or three times the enemy will be routed and disappear; but care must be taken that the plants do not become too dry again. They will stand well in a glass entrance porch, or under a verandah. Very slight protection from frost is necessary for the early-flowering varieties of Chrysanthemums; in fact, in seasons like the present many thousands have been grown without any protection at all. R.

4947.—Vallota not flowering. There must be something wrong at the root of this Vallota Lily, as it does not thrive and increase as the bulbs usually do, although the leaves commonly turn yellow and fall during the winter. Perhaps the drainage is in fault, or worms may have entered the pot, when they destroy the young roots as fast as they are made, and thus cause much havoc, preventing the growth of any plant. "A Lover of Flowers" should turn the ball of the roots into the left hand carefully, without much disturbance of them, and ascertain whether this enemy is present, which may be known by the rut-like little roads a worm always makes between the pot and the soil, and if so turn him out. Should there be difficulty in finding him, replace the plant in the pot and lower it into a pan of lime-water—made by stirring a lump of lime the size of a teacup into 2 gallons of water, and letting it stand till clear and cold—when the worms will usually come out at the top to avoid the lime-water. It is now late for repotting, and Vallotas dislike to be disturbed; but in the case of worms in the pot it is necessary to get them out at any risk. If the soil should be

Oliver's Sea Holly (E. Olivieranum). (See "Cut-flowers in the House.")

found to be sour, the bulb would be better taken out of it and planted firmly in good, sweet soil, with leaf-mould, soot, and sand mixed with it in small quantities, and the plant should be kept rather dry, though not dust-dry, until it begins to make growth in the spring. Vallotas like to be near the surface, and, in fact, push themselves almost out of the ground in time. They should not be repotted when healthy for years, as they bloom best when tight in their pots, but supplied with liquid-manure—soot-water being the best of manures for room-plants—and a mulch of rich soil between the bulbs in spring. These little tips and hints, when being properly ripened

in July and August, when they should stand in the open air, if possible, in full sunshine, being applied with plenty of water or liquid-manure at the same time. An easy way to give this, when the pot is very full, is to place them in a saucer of soot-water; but they should not stand in water at any other time of the year, and a saucer, if used, must be empty in winter.—I. L. R.

GENISTA FRAGRANS (CYTISUS RACE-MOSUS) FOR A ROOM.

THESE plants, covered with brilliant yellow blossoms, are sold in large numbers in our streets during the winter and early spring, and few flowers are more decorative for the table or drawing-room, while the *Idem* lists, the fresh flowers, too, being an additional charm. With good care and cultivation the *Genista* will produce flowers in succession from early spring to late autumn; but too often room plants, exposed to gas, and insufficiently watered, soon drop their leaves and become unhealthy, when the flower-buds shrivel away, and the beautiful perfume becomes an eyesore. Many of the forced plants sold in the street receive such a serious check from being taken out into the cold wind from a forcing-house that they never recover it, and for this reason they are best bought during a mild break in the weather, or from a reliable nurseryman, who has not over-colded the plants for early sale. The earliest *Genistas* are already in bloom, but those who have a warm greenhouse must take special care of their plants when in bloom at this time of year. They must never be exposed to gas, which has a singularly drying effect on the air, and all room plants do best when it is not humid. If, however, gas is unavoidable, the plants should be removed before it is lighted, into a bathroom with hot-water pipes, or a bedroom, where they can stand until the sitting-rooms have been thoroughly aired the next day. A slightly damp air, in a temperature of 50 degs. to 60 degs., is a great help to room plants at night, but this is not easy to procure without a warmed conservatory. A bathroom, where warm water can be turned on to mist the air two or three times in the day, is often useful in this way, if the hot-water pipes are kept warm at night by banking up the kitchen fire; or, failing this, the plants may be kept in a room with a fire, if they are given a large tray, or flat bath, containing a layer of Moss or Cheong-mat-fibre, which should be kept moist from a rosed watering-pot, the plants standing on inverted saucers, not in water. Plenty of sunshine and air should be given to room plants in mild weather, but during a frost, they should be removed from the window, and covered with newspaper in a sheltered corner at night. *Genistas* stand well in a verandah or balcony during the summer. If they are not back and repotted (using good loam, leaf-mould, and sand as a compost, with plenty of drainage) after blooming, they will make fresh growth, which is often again covered with blossom. They are propagated by cuttings or slips in the spring, but these require the help of coal, dust air to make them take root. This can be supplied by sinking the pot of sandy soil, well drained (in which five or six cuttings can be firmly ranged round the edge), in a box of glass ashes, which can be covered with a piece of glass, the surrounding ashes being kept moist and the glass turned or wiped daily, until the little plants are rooted. L. R.

4971.—**Draining a garden.**—In country districts it is nearly always possible to find a good labourer that has had some experience in draining, and with one good man to clear out the bottom and lay the pipes, ordinary labourers can clear the top. The cost would depend upon the character of the soil, the cost of tiles, and price of labour in the district. This would have to be arranged on the spot. For garden culture it would be a very good plan to burn some of the clay, pass it through a screen, put the rough over the drain-pipes to the depth of a foot or so, and scatter the fine stuff over the land. This would make a permanent improvement of the utmost value.—E. H.

Cosmos bipinnatus.—This has been very beautiful this year, and it is an annual that amateurs might grow more often. The plant

makes free, feathery growth, and the flowers vary in colour, rose-purple and white. The white kind is charming, one of the most graceful plants of the garden. It likes a warm summer, hence its beauty this year. Get a good clump of it, choosing a rather warm position for it. Seeds should be sown under glass in February in the usual way, and the young plants put out when frosts are over. They will be in bloom throughout the autumn months.—V. C.

FRUIT.

WINTER PRUNING.

THIS is the best time to get on with the pruning of nearly all kinds of fruit-trees and bushes, for although such work can be done during severe frost, I question very much whether that is the best course to pursue. For myself I would sooner keep all the wheeling of manure, grubbing up old trees, etc., for frosty weather, and push on the more important work of pruning while it is mild. Doubtless there are still many who think that pruning is unnecessary, but I think that the best argument in favour of it is found in the greatly increased size of the fruit, borne by trees systematically pruned, compared with those borne by trees left in nature, and we all know, by the experience of the past season, that it is only fine fruit that pays to cultivate. But pruning, like any other thing, can be overdone, and thereby brought into disrepute. I will briefly describe how I prune, and I grow fruit-trees for profit, and unless they yield some they are soon grubbed up as useless. In the first place the more you cut a tree the more wood-growth there will be produced—as a rule; and some kinds such as the Stone Apple can only be kept from getting into a stunted condition, or really all fruit-trees, by cutting off the tips of the shoots, and you will find that trees that have been over pruned, such as pyramids of strong growing kinds that have been sheared off to one uniform height, whether it suited them or not, produce a thicket of gross, sappy wood, quite useless for fruiting; but this is really not pruning at all, and would be more correctly described as mutilating.

STANDARDS or dwarf-stemmed trees that are allowed to develop large heads require very little pruning after they begin to fruit. Young trees for the first three years after planting require a little thinning out, so as to get an evenly-balanced head of branches, shortening any extra strong shoots that are not growing the others; but after they bear full crops of fruit it will, as a rule, be best to keep the centre of the tree cleared of all useless spurs and spray, so as to throw all the vigour into the shoots that are fully exposed to sun and air, as this is where the finest fruit will be found.

DWARF TREES are very useful, especially for small gardens; but they should not be kept cut so closely as one frequently finds them, young wood being absolutely necessary to keep the tree in health, and a few of the older shoots should be removed altogether every year, and young shoots trained in, as it will be found that the finest fruit is borne by the topmost or youngest wood, and trees that have been closely pruned several years ago greatly benefited by cutting off the lowest lot of branches altogether, and the weight of fruit will soon depress the second tier into their place. It is a mistake to reduce the terminal shoot to three or four buds, as half-a-dozen is a good deal better, and, above all, keep the shoots thin. It is surprising how little wood will produce a heavy crop of fruit if it is of the right sort. As these kinds of trees are easily replaced, it is not advisable to let them stand for any great number of years.

PYRAMIDS are the form mostly favoured for Pears—in fact, some kinds grow quite naturally into a good pyramidal form, with very little training. The main thing in their culture is to thin out the centres, so that they get full light in all parts of the tree, and if not too formally grown they are a very serviceable form to adopt.

ESPADERS, or horizontal trained trees, to either stakes or wires, is one of the oldest and most useful of all forms of trained trees. They occupy but little space, and produce fine, well-coloured fruit in quantity.

WALL TREES, of all kinds of training, need as much of the old wood cutting out and replacing with new as the form of tree and mode of

growth admits of. Peaches, Nectarines, and Morello Cherries are as a rule pruned on the system of cutting out all exhausted wood, and replacing with that of the current year's growth, and it would be well if this were partially adopted with other fruit, for there can be no doubt but that the finest fruit is borne by young wood, and although Plums, Pears, and some other fruits do not flower freely on the previous year's wood, there is no question but that they all fruit more freely, and the fruit attains a greater size on wood that is comparatively young, and for this reason old, hard spurs should be shortened back close, so that they may renew themselves, and there should be a constant relay of young wood all over the trees if fine fruit is plenty to be grown.

JAMES GROOM, Gosport.

4964.—**Planting Raspberries.**—The best and the least expensive way of planting Raspberries is to plant in rows 7 feet apart, the plants to be 2 feet apart in the rows. Cut down nearly to the ground first season to give a chance for the plants to get well established. Afterwards prune to 3 feet, and let the plants produce the crop nearer the roots than is customary. If well-ripened 3-foot canes will bear as much fruit as if left 18 inches longer, and the expense of the crop will be less. Good varieties are Hornet, Norwich Wonder, Superlative, and Fastid. The last is a good sort for preserving, but will not grow so fine as the others.—E. H.

4965.—**Making cider.**—In cider-making counties proper mills for grinding by manual labour the Apples, and presser to press out the juice are provided, and where there is any quantity to make these appliances are indispensable. After the fruit is ground into a pulp it is laid on the bed of the press, with a little clean wheat-straw to help to bind it together and prevent it from bulging out at the sides. The top of the press is then brought down, and a large screw from above is worked by leverage with sufficient force to press out all the juice. What was rather a high square heap at first is reduced to a comparatively small mass. The juice is, of course, collected and placed in barrels as soon as it is made. In three or four months after it is raked off—that is, all the clear liquid is drawn off and put into another barrel, and the sediment at the bottom of the cask thrown away. When sweet cider is required, the sour and sweet Apples are kept separate, and used in that way.—J. C. C.

4921.—**Pruning Fig-trees.**—I would advise "Babcock" to leave his Fig-tree unpruned until the spring. Figs, as a rule, do not require much pruning, but it all depends on whether it is trained to a wall or fruits as a bush tree. In the latter case pruning is unnecessary; but on a wall the wood must be thinned out, so as to allow space for the foliage to spread out. The best plan is to cut some of the longest and barest shoots right back to the base, and keep taking up a few young shoots every year. As the Figs are borne on the tips of the last season's wood, those that are half-grown now are useless, and if not pulled off will drop off next season. It is the ones just formed, but not much more than half-grown, that will form next season's crop; and in cold localities it is best to tie the shoots up in bundles and protect with straw, Fern, and evergreen branches. When these are taken off in spring is the best time to prune.—J. C. Hants.

4903.—**Gooseberry-caterpillar.**—How often have I seen this question in GARDENING, and never yet have I seen it answered in the way that I found it quite effectual! A dozen years ago my Gooseberry-bushes were almost stripped by caterpillars, and my gardener killed them all (in summer) with one shilling bottle of Fir-tree-oil, mixed with water, as directed, and distributed with a large brass syringe. What fell off the bushes fell into the ground, and did not hurt the fruit, but killed any eggs that might be there. For ten years I never saw a caterpillar, and now if a lush shows any a small dose of the oil puts an immediate stop to the plague.—ADMIRAL F. A. CROSE.

4923.—**Grafting or budding Cherries.**—Cherries are usually budded, and the budding is done end of July or beginning of August. The bud is inserted in the side of the stem near the ground. The bud will remain dormant during the following winter, and break the next spring, when the stock should be headed down.—E. H.

CHRYSANTHEMUMS.

Pompon Chrysanthemums. — The Pompon Chrysanthemums are amongst the most beautiful of all, the plants free, and the flowers produced in profusion. One of the more popular is Mlle. Elise Jordan, and when grown freely blooms profusely, its flowers neatly shaped and rosy-pink in colour. A few good plants will make a pleasing display in the greenhouse. Two very good new kinds are Laine Fleuri, the flowers orange-yellow, and Marmon, which is one of the most charming recent novelties. The flowers are of true Pompon shape, very neat, free, and in colour rich-orange, a lovely and distinct shade. Eynsford Gem, purple, shaded with rose, is a good variety. The best Poppoms are: Black Douglas (the flowers deep-crimson), Bob (brownish-crimson), Cede-Nulli (in its several colours), La Neige (pure-white), Marabout (white, with fringed florets), Resonance (rose), Scapine (a fringed variety rose-crimson in colour, and with pleasantly scented flowers), Snowdrift (a beautiful white flower), Golden Mlle. Marthe (rich-yellow), St. Michael (similar colour, a variety usually grown for specimen plants), St. Thais (brownish-orange), and Tricolore (especially the white form).—V. C.

4987.—An amateur Chrysanthemum grower.—As I was connected with a Chrysanthemum show for some years, in which many professional and amateur gardeners exhibited, I can well assure that there are some things done that one would rather see left alone; at the same time, I do not see that there is anything very objectionable in what this correspondent complains of. If there was nothing more serious done before the show, the managers and members could very well pass unnoticed the selling of a few blooms at the close, and I do not think that such an action disparages anyone who does so. There is not any recognised rule in an amateurs' society that will apply to the inquiry referred to, and if the correspondent wishes to establish such a rule he should get it inserted in the rules of the particular society to which he belongs. A kind of mutual understanding between members and exhibitors is not enough, because all men are not conscientious. There must be a clear and well-defined rule made and adhered to if things are to work pleasantly.—J. C. U.

— "Bubs" has touched upon a raw spot. The better plan so far as the Chrysanthemum show is concerned is to drop the amateur classes and let all show together, having plenty of classes, so that all may have a chance of winning in somewhere, only making a rule so that no exhibitor shall take more than two prizes in any class or classes, &c. Many of what used to be the leading amateurs in many societies sell something or other. They may not do it openly in the way stated, but it is done, and my word sets the example, and I very much doubt if anything done or said will alter it. Modern ideas are trending that way, hence the best course is, I think, to sink the amateur class altogether, and let all compete on equal terms. But I think all respectable societies should stop all sales during the show. I believe I saw at the Aquarium show the other day a notice exposed over one stand containing the words in big type, "These blooms for sale." Business is usually done at these shows, but it might be kept in the background a little more.—E. H.

4988.—Plants in pots and boxes.—If the soil is turned in the pots and boxes, and exposed to the atmosphere in a corner of the back yard, a good deal of it might be used again next year. A little fresh loam or something of the kind to mix with it, and a little old manure to revive it, will make it answer the purpose again very well. Getting good soil is one of the difficulties of the town gardener, and by exposing it now and through the winter it will be better than keeping it in the boxes.—E. H.

— More especially as yours is evidently a "town garden," I strongly recommend you to get rid of the old soil and procure a fresh supply from some country place for your pots next year. The constant watering, as well as the demand made by the roots of the plants, not only extracts the nutriment from it, but renders it more or less "sour," and if used again the plants will not thrive as they should. If you

really cannot get fresh, turn the old out into a heap fully exposed to the weather for the winter, adding a little lime to it. Burn part of it if you can, and before using it again add a fourth of decayed manure or leaf-mould, and a dash of some good artificial.—B. C. R.

FERNS.

CHOICE FERNS.

LEPITYSIS SEPTATA.

This species, the subject of our illustration, is a very handsome Fern, well deserving cultivation in even the choicest of collections.

Front of Lepitysis septata.

Lepitysis is a small genus, nearly allied to Polypodium, from which it differs in having netted veins; thus it comes near to Goniophlebium, from which it may be distinguished by the underside of the fronds being densely clothed with ciliated scales. It is an evergreen warm-house plant, the fronds attaining a height of from a foot to 18 inches on well-grown examples, are lanceolate, or ovate-lanceolate in outline, pinnate, the pinnae being closely set and sessile, the under surface being thickly covered with ferruginous scales, through which the yellowish-red sori protrude. The specimen here figured was grown in the nursery of the late Messrs. Rollison, where many rare and beautiful Ferns are always to be found. It is a native of Brazil, Mexico, and Peru.

INDOOR PLANTS.

Begonias.—It may interest those who are fond of Begonias, but who have hitherto hesitated to grow them outside in cold and wind-swept districts, to know that an experiment made with them in Shelton this year has been very satisfactory. A few of last year's seedlings were planted outside in June this summer, and flowered continuously and well till the end of September, when a hand-light was placed over them to guard against frost. Now that the tubers have been lifted, they are found to have more than doubled their size while in the open ground. I hope that this may encourage others living in cold, exposed districts to try them outside next season.—K.

A fine Fuchsia.—Decidedly the finest double-flowered Fuchsia in cultivation is Mrs. A. Huggatt, one of Mr. Fry's seedlings. The tube and sepals are of a deep glossy crimson colour, stout and well reflexed, while the large and full corolla is of a deep purple-crimson hue above, and pure-white towards the tips. The substance of the whole flower is extraordinary, and the habit of the plant is dwarf, compact, and bushy to a degree, with small and very neat foliage.—B. C. R.

A new Zonal Pelargonium "Raspail Improved."—That familiar and most useful variety, P. V. Raspail, which may be described as the finest zonal-double variety certainly—erect raised, has a second time produced a distinct and highly valuable sport. Its first departure, known as Turtle's Surprise, was distinguished by a much more dwarf and compact habit than its parent, as well as being even more floriferous; but this time the "sport" is in the other direction, the "Improved" form having thicker and stronger stems, larger leaves, and both pipes and trusses fully twice the size of the typical plant. The trusses are simply enormous—too large, in fact, for banquet work—but the single pipes, which are of much the same colour as in the type (a rich crimson-scarlet), are so large, with thick, shell-like petals, that they may prove useful when wired up singly for making up button-holes and so forth. As so frequently happens, this remarkable "sport" occurred in at least two places at the same time, and the foreman in a large and well-known nursery told me that he had only a few days before noticed that one of the plants of "Raspail" was making an unprecedentedly vigorous growth, and producing some enormous trusses, when a man brought a specimen bloom of the very same break which had occurred with him also. Every collection should include this really remarkable novelty.—B. C. R.

4975.—Cacti from Mexico, &c.—It is obvious that unless you can enter into some compact with a collector, or you have a friend in Mexico, you cannot get the plants. The only way is to treat with a collector who is going up the country, and make arrangements with him. I do not know what the cost would be, as much depends upon circumstances; but I think there is little demand for Cactus plants here, unless for the many beautiful hybrids of Phyllocactus, as J. T. Peacock and others.—C. T.

4920.—Cinerarias in a cold frame.—In reply to "Rector" as to whether Cinerarias in a cold frame should be watered overhead with a rose pot, or at the edge of the pot through the spout of water-pot, I should decidedly put the rose away after October, for in cold frames dampness causes more loss than actual frost, and in watering with a rose you not only wet the parts requiring moisture, but you wet the parts that should be kept dry, and although Cinerarias are moisture-loving plants, and should never get quite dry, yet when kept in cold frames at this time of year they require extra care in covering the exterior to keep out frost, and when watering requires to be done I always do it about ten o'clock a.m., leaving the lights open until the afternoon to dry up superfluous moisture, and in the South of England, Cinerarias for late flowering can be grown in frames up to the time when they show flower, and can then be removed to a drier atmosphere.—J. G., Hants.

4984.—Temperature for a greenhouse.—For "Geraniums" a temperature of 45 degs. to 50 degs. during the winter is ample, and with 10 degs. more they ought to bloom

freely, but in this case they must be kept near the glass, on shelves, etc. In order to keep *Colera* alive the temperature must not fall below 55 degs., with an occasional rise during the day of 5 degs. or 10 degs. more. This is where the disadvantage of growing in one house plants that require such different temperatures comes in—you cannot do both justice. *Rhynchospora* requires a warmth of about 55 degs. while being forced, and in the whole you should endeavor to keep the house at about this temperature, seldom less, and with a rise to 60 degs. or so when the sun shines. Keep the "Germanias," etc., on shelves near the glass, and the *Colera* at the warmest end or part. Seventy degs. at night is altogether too much; you must not have much steam about, and if the stove gives off too much heat I should say the best plan would be to surround it with brickwork; even a single brick would make a lot of difference.—B. C. R.

PERSIAN CYCLAMENS.

The Cyclamens now so largely used for pot cultivation are almost wholly confined to the race of seedling varieties of *C. persicum* that in recent years have been so much improved both in the size and colour of their flowers, as also in the disposition to produce them in much greater quantities than the original species could be induced to. So great is the improvement that the Cyclamens of the present day are amongst the most beautiful and continuous bloomers of all greenhouse plants. The cultural treatment, with more warmth stimulating quick growth, that this new race is found to best succeed with, is very different from the old school method of growing them, by which the plants were yearly, after blooming, subjected to a severe drying process whereby they were much enfeebled. The ordinary, and much the best way of propagation is from seed, which may be sown at different times of the year, according to the season they are required to flower. If well managed the plants will be large enough to admit of flowering when from fifteen to eighteen months old. To bloom in spring sow about November or December; if wanted to come into flower during the late autumn and winter months sow about the end of July, in shallow pans filled with a mixture of sifted fibrous loam, with some leaf-mould and a little sand added. Press the material moderately firm, scatter the seeds 1 inch apart over the surface, and cover them with about a fourth of an inch of the soil. When sown at this time stand in a temperature of about 60 degs., where they will soon vegetate if the soil is kept a little moist; to do this without giving too much water a thin paper may be laid over the surface and removed as soon as the plants are up, after which they must be kept close to the glass, and the sun not allowed to reach them. The best place in which to grow them through their early stages is a low heated pit where an intermediate temperature (which is necessary) all through the first autumn and winter so as to get them on large enough to flower satisfactorily by the close of the ensuing year and on through the subsequent winter) can be kept up. Give a moderate amount of air daily from the time the young plants are up, keeping the atmosphere a little moist, and syringing slightly in the afternoons; as soon as large enough to handle move singly into small pots, using soil similar to that in which the seeds were sown. Stand them on a moist bottom, still close to the glass; leave off shading as the soil decreases in power, and keep up a night temperature during the winter of about 50 degs., in which they will go on growing so as to require watering at the beginning of April into 3-inch pots. Then use similar soil, but add a little cow-mannure that has got old and mellow. They will now require a little more warmth, and until the season is farther advanced enough fire should be used in cool weather to keep them up to 55 degs. in the night, and proportionately higher by day when there is an absence of sun to raise the temperature.

A thin shade will again be needful through the spring and summer whenever the sun comes on them. Care must be taken at all times through the season of growth that they never want for water at the roots, or they will receive a severe check. Keep the atmosphere and the material on which the pots stand moist, syringing overhead each afternoon by which a

quiescent to keep them free from red-spider. Give air every day, but avoid draughts; towards the end of June move the plants into 6-inch pots, which will be large enough to flower them in the first season, and use a fair amount of drainage. Continue to treat as hitherto advised in the early part of the summer until September, when give more air, and discontinue shading and syringing so as to solidify the growth and induce the formation of flowers. Still let them have a position near the glass, but through the autumn and winter let the material in which

A root type of White Cyclamen.

the pots are dry. If each plant is now stood on an inverted pot it will allow a better circulation of air round them; with the same view do not crowd them too close—a condition that should in all the stages of growth be avoided or the leaves will get drawn and weak and the plants spilt. If all has gone well they will now be sturdy examples, with short stout leaf-stalks, the foliage half covering the pots; they will flower freely through the last months of the year and early part of winter, during which they should be kept in a night temperature of 45 degs. or 50 degs.

After blooming keep a little cooler, and when all danger of frost is over they may be turned out under a north wall, the pots plunged in ashes, or, still better, they may be kept in a cold frame, placed where they will be out of the full sun, and given enough water to prevent the soil getting quite dry. The plants will lose most of their leaves through the early part of summer, but will afterwards push up quantities; as soon as these are visible give more water, and when a little growth has been made move into pots a couple of inches larger, shaking away the old soil and replacing it with new of a like description to that hitherto recommended. Afterwards stand them in a pit, frame, or house and treat as advised for the preceding season, except that they will not now require to be kept quite so close. The ensuing winter the plants will yield numbers of flowers proportionate to the increased size they have attained. After blooming again treat as in the previous spring and summer in the matter of standing out, repotting, &c. They may be kept on after they have again flowered, or be discarded and their place taken by younger stock, which it is well to keep coming on by sowing some seed each season. When the sowing is deferred until autumn keep a little cooler both before and after the plants come up, and it will be well to prick them off when large enough, 2 inches apart in pans, allowing them to remain until spring before potting singly; afterwards treat as advised for the early sowing stock. Red-spider, to which they are liable, will usually be kept under by following the course of cultivation detailed. Thrips and aphids sometimes attack them, getting to the undersides of the leaves. These insects should be repeatedly sought for, when discovered dip in Tobacco-water or the same with Tobacco.

Indian Azaleas for forcing.—The most promising-looking plants of the best kinds for early forcing may now be placed in warmth. They can thus be had in flower by the middle of January without any unwholesome. The florists I know have been cutting Azalea flowers for some little time past, but as far as this pertains to private gardens, there is no practical utility in it. In these latter a succession is more what is wanted, whilst in the former it is more a question of getting the best price for the blooms. I do not favour bottom-heat even of leaves, but have no objection to standing the plants over fermenting material, the moisture arising therefrom being decidedly beneficial in encouraging the buds to swell freely. Too much water at the roots must be guarded against, but the plants must not suffer from the opposite extreme. By plying the syringe freely, thrips, &c., will be kept down, whilst it will also save watering. When plants have been forced a few seasons they will quickly respond to a little warmth about now; in fact, at times they will flower almost without any additional warmth. I have noticed this in the case of *Roi Leopold* and *Deutsche Perle*, particularly the latter. The old white alba and *Fielder's White* with *Deutsche Perle* are about the three best of their colour. Of the striped varieties, *Roi Leopold* alba, *punctata rosea*, and *vittata elegans* are all reliable, the two latter hardly wanting any forcing. In the reds, *Roi Leopold* is still one of the most reliable to force early of the large flowered type; *calyciflora*, a bright salmon-red, larger than, but somewhat similar to, *amena*, is a free-growing and as free-flowering a variety as that old kind, which should also be included. Another fine old kind is *obtusum*, a variety that is, in spite of its age, not nearly enough grown. The foregoing, as the earliest, are about the best to choose, as expensive kinds are not desirable.—H.

4973.—An unheated frame.—You can't grow any except hardy Orchids in an unheated frame, although it may be used for *Cypripedium* insignis, which does not need heat during the summer, although often seen in an intermediate temperature. The less artificial heat given to this species the better, taking it to the greenhouse in September to flower, which it will do through the early winter. *Cypripedium spectabile* is as beautiful as any indoor kind, more so than many of the dingy-coloured hybrids, praised for virtues they do not possess. It will grow well in a peat and loam soil. *C. calceolus*, a British Orchid, now nearly extinct, is very charming, the sepals and petals deep brown and the lip yellow, and *C. guttatum* compose a good trio. The latter has very distinct-looking flowers, and *C. pubescens* may be added. One of the most handsome of all Orchids for pots is *Orchis foliosa*, which is very vigorous in growth and free. One often sees names of it in exhibitions. It varies in height, but is usually about 2 feet. The flowers, borne numerously on a strong spike, are of a purplish colour, deeper in the lip than the sepals and petals. It blooms in May. You may also choose *O. latifolia* and *O. maculata*. These are the cheaper and more vigorous kinds.—C. T.

4982.—A lean-to greenhouse.—With a house of the dimensions you give, you should not have any difficulty in keeping out the frost with a good oil-stove, such as Toope's or Rippling's, with an extra lamp, perhaps, in very severe weather. And if you only use the stove when the temperature in the house falls to the freezing-point, you will be more likely to save your plants than by keeping the house warmer by the same means. It is the constant use of the oil-stoves in greenhouses that injures the plants, whereas they ought not to be lighted until there is danger of the frost entering the house. In such cases as this inquiry refers to, it is better to keep the soil in the pots rather dry than wet, and to open the top ventilators a little every day when it is not freezing, and in mild weather a current of air should pass through the house by opening one or two of the front ventilators.—J. C. C.

—Certainly. An apparatus consisting of two rows (or six or 20 feet) of 3-inch piping, and a properly-constructed copper boiler to consume paraffin, would do all that is required with a minimum of trouble, and the cost would not be great. In case something still cheaper would be preferred, a couple of the little oil-heated

stoves now made so well and sold so cheaply would exclude any ordinary frost from a house of this size, especially if a thick, warm covering or blind could be drawn over the roof on cold nights. Use the stoves only when necessary, employing the best oil and keeping them clean, and give air freely whenever the weather outside is moderately mild, and all will go well. In severe weather it is better to keep the plants, Geraniums, &c., especially, moderately dry.—**B. C. R.**

ROSES.

SEASONABLE NOTES.

Now that "chill December" is with us, and boisterous winds are swaying the most valuable growth of Roses about, no time should be lost in securing them in some way. On no account follow the plan many have been in the habit of doing, and cut off these strong shoots. I have often seen them cut back severely, and when inquiring the reason, have been told it was to balance the growth! Now this is quite a mistaken idea, as each variety has its own characteristic, and it is natural for many to make a few extra vigorous shoots. Indeed, the most valuable wood of this class consists of the strong shoots produced late in the summer, and which I am now calling attention to. If removed so completely as I have often noticed, the plant simply devotes its energies to producing more of the same growth; and a little thought will show us the reason for this. As the extra strong growers (no matter what class or section they may belong to) flower more freely upon the maiden wood of the preceding year, it is only natural for the plant to produce this in the endeavour to follow Nature's laws and reproduce its species as freely as possible. Growers of these vigorous varieties require quantity of bloom in preference to quality; fortunately a full meal of the litter can be had without loss of quantity, as this section provides us with a vast number of blooms of one stamp. Other Roses are more amenable to culture as regards quality of their flowers. If we allow wind to sway these branches about, they are often much chafed against one another, or else broken off entirely. It is very simple to secure them to a stout stake, if in the open border; or by a few strong shreds if against a wall or fence. I would not tack them in their permanent position now, but simply make them safe from injurious rubbing and swaying.

MULCHING AND PROTECTING.—Now is the best time to apply manure to the Rose-beds. In the first place we can get at it better, and the stimulating effects can be retained in the soil until wanted; it will also act as a considerable protection from frost. My own plants are all earthed up similar to Potatoes when first coming through the soil. I am now alluding to dwarfs only. In this class of plants the most vital and important part is the crown, or lower eyes. If this be covered with soil or rough manure no amount of frost will affect them. Even if we get weather sufficiently severe to kill or seriously cripple the top growth, covering the base of the plant in the way described will secure a few healthy eyes that are sure to do well the next summer. I do not believe in protection to the extent many practise, as even in the north Roses are among the hardiest of flowering shrubs; but it is one thing to go the extreme and quite another to afford a little judicious protection, especially to a few of the more tender constituted varieties. One of the simplest and quickest forms of protection consists of sticking a few branches of Fir, Horse, Birch, &c., between the plants, care being placed on the north and north-east sides. These are far preferable to shaking litter among them, as rain causes this to clog around the base, and when frost comes the frozen moisture is even more injurious than if no litter had been applied. Wind also removes it, and as a frost-laden wind is by far the most destructive agent, it is much wiser to shelter the plants with twigs as suggested. When the weather is open the twigs do not need removal, as they allow of light and air having free access to the plants, while Bracken, straw, and litter do not. The heads of standards may be drawn together slightly, and then have a few branches tied around them.

CUTTINGS.—Some time ago I gave a few hints upon the propagation of stocks from cuttings,

also of Roses. These will be much better if a little protection can be afforded should hard weather set in. Amateurs only need a few, and their stock is easily sheltered with a layer of Pea-boughs, or similar branches. Very little shelter is all they need, and this small amount of trouble will be paid for with a far more satisfactory strike than if left entirely to chance. On an emergency a slight scatter of litter might be given, but should be removed directly the frost goes, as it will keep the tops wet, and more liable to harm later on. Finally, it is astonishing how much frost a slight protection of branches will keep off; and as they are quickly applied, and do no harm if allowed to remain, I much prefer them to any other. **T. U.**

TEA-SCENTED ROSES AND THEIR USES.

The above heading suggests rather an extensive subject, for the purposes to which this popular section of Roses can be put are many and varied. As this class has been so much improved of late it is even more serviceable than before. Not a great many years ago there was among the Tea-Roses few climbers that had any pretensions to quality. Now, however, we can number some of our finest Roses among these, whether as individual towers or collectively as masses for effect. They have also been greatly improved in constitution, for we have many varieties that are among the hardiest of all Roses. As garden Roses they are surpassed by none, while to the exhibitor they are invaluable—so much so, that of late classes have been devoted exclusively to them at the majority of Rose shows. It matters little in what form or position one requires the Rose; he can be well suited from among this class. For forcing under glass, covering walls, arches, pillars or trellis-work as dwarfs or standards in the Rose garden, the Tea-scented Roses are equally at home. The earliest as well as the latest Rose of the year is almost certain to be one of this class, while for delicate perfume no flower can surpass them. There is such a large amount of vitality about this section, that all of the varieties will thrive much better as standards than any of the Hybrid Perpetuals, excepting those of very vigorous habit. They will also grow in any soil and any aspect, and are free from red-rust and Orange-fungus. Their

Rose shows scheduled a class for six or twelve kinds fifteen years ago, we now have classes of eighteen, twenty-four, and even thirty-six varieties; more than this, they are shown in trebles up to the twenty-four class. Twenty-four trebles of Tea-Roses would have been declared an impossibility only a few years ago; not but that the number of varieties was easily obtainable, but it is the high standard of the present day exhibition flowers that would have been deemed the difficulty. In looking over a box of eighteen treble Teas four years ago, I was surprised to find that no less than fifteen of the varieties were of comparatively recent introduction. None of the Tea-Roses are so useless and deceiving to the amateur as many of the show varieties of the Hybrid Perpetual division; such, for instance, as Emile Hansburg and Horace Vernet—two grand Roses as seen on the exhibition stand, but quite useless for any other purpose, and even as exhibition kinds causing a great deal of trouble and seldom giving a flower. You may choose among the show Teas and be certain of being pleased. Such free-growing kinds as Anna Olivier and Marie Van Houtte (here figured) will climb very well if given a little time, although they are not generally considered as climbing varieties. Under glass is where the true beauties and charms of the Teas are most generally found. Here they throw enormous quantities of flowers, that are all exceedingly pretty and useful on account of being free from dirt. When growing in the open air, large numbers are often spoilt by unpropitious weather.

TEA ROSES should be grown on the Brier stock in some form. It matters little whether they are on dwarfs of the cutting or seedling Brier, or upon full or short standards of the hedge Brier. I much prefer them on the short hedge Brier, say with a stem of 18 inches to 24 inches. In this form, such dwarf and drooping kinds as Souvenir d'Ami and Niphotos are much better than as dwarfs. Their flowers in this way are kept away from the dirt, and at the same time the plants have not to obtain their nourishment through a great length of a Brier stem. The blooms of the Tea-scented and Noisette Roses last much longer when cut than the majority of those of the other classes, nor are they so liable to lose their colour and freshness as those of the Hybrid Perpetuals. Taken as a whole, a dozen plants of Tea-Roses will give three times as many flowers as the same number of Hybrid Perpetuals. The so-called "Perpetuals" do not flower more than twice during the summer, while the Teas will give from four to six crops of bloom. The flowers are also produced in greater abundance and in larger trusses.

R.

4890.—Marechal Niel Rose in a pot.

—Seeing your plant is so weak, I would advise your cutting it back at once. You will then secure a good growth during the coming spring and summer, provided the plant is in a healthy state now, and receives a due amount of attention. An unheated lean-to house, with south-east exposure, is excellent for this grand Rose; but you must first of all get some long and well-ripened wood upon your plant, or you will not have satisfactory results. Prune it hard back to the two or three lowest healthy eyes, and grow generously as soon as the roots are well to work.—**P. U.**

— You had better remove the flower-bud at once. If you do not do so it will most likely drop off, as there is not warmth enough in an unheated house to cause the bud to open. If you want to get a strong plant you must give it a larger pot in the spring, or about the beginning of March; one 14 inches in diameter will not be too large. Do not prune the plant this winter. You are more likely to get a stout shoot or two from near the base next year by leaving it alone than by hard pruning now.—**J. C. C.**

4968.—Rose W. A. Richardson.—This Rose is quite as hardy as the majority, and the south-west aspect you mention will suit it admirably. It will be better if a little natural shelter exist against the south-west winds, as these are apt to buffet the blooms and growth, often spoiling a crop of flowers. You may plant now or in the spring. Unless severe weather sets in I should plant now. You ask if it should be cut back or not. Much depends upon

Tea Rose "Marie Van Houtte."

freedom from these two diseases is a great point in their favour, as there are many of them well worth growing for the charming metallic hues of their foliage. Few things in the culture of Roses are more disappointing than to find the plants suddenly attacked with these blights, and the rapidity with which they turn the leaves rusty and shabby, causing them to drop and leave the plants bare in a few weeks or even days, makes the Tea-scented class of Roses a more than ever. As a proof of their great improvement both in quality and quantity of varieties, I may state that whereas only a few

whether the plant be in a pot or lifted from the open ground. Any wood upon it in the latter case will be of little service during the coming year, and may be pruned back partially now, and the job completed in spring. If from a pot, and carrying a good healthy rod or two, wait until spring. Then only shorten the growth slightly, and follow the instructions which will appear in these pages in due course.—P. U.

—Yes, this Rose will grow and blossom well in a south-west exposure. With regard to planting—if your plant has been taken from the open ground it may be put in at once in mild weather. If it has been in a pot and kept under glass you had better defer the planting until the spring. You do not say what form you intend your plant to take, whether as a climber or a bush. If it is intended as a climber it will not want cutting back. If it is intended for a bush any long shoot may be cut back in the spring to within 2 feet of the ground.—J. C. C.

—This Rose will do well in a south-west exposure, and it may be planted now. Prune back to well-ripening wood in spring.—E. H.

ROSES AS STANDARDS.

It is not many years since the bulk of Roses were grown in this form, but probably there are not more than one-tenth so cultivated at present. Why is this? I think the majority of my readers will be quite ready to agree that the following reasons are quite sufficient to account for their evident decline in popularity; Standards do not produce so many blooms. They are much shorter lived as a body, far more susceptible to a severe winter, and cost about three times as much as the same Rose would when cultivated upon some stock of a dwarf character. In order to start upon a fair basis, I will now enumerate one or two points in their favour. They are exceedingly useful in showing off the weeping or drooping tendency of some of the prettiest climbers, and are also very showy on the outskirts of a lawn, or in the centre of a bed of Roses. But the main idea when starting these notes was to warn against ordering Roses upon the standard Brier stock before knowing if the variety is thoroughly suited. I should have no difficulty in naming upwards of fifty choice Roses which positively refuse to thrive upon standards for any length of time. The same varieties will do well as dwarfs, but do not possess sufficient vigour and vitality to be satisfactory in standard form. The question of standard *versus* dwarf Roses has frequently been mooted in the horticultural press, but like many another subject upon which there are different opinions held a middle or medium course is much the wisest. Few—I may say no Roses refuse to do well upon short stocks of the hedge Brier; and I certainly lean strongly to the opinion that most of them produce superior blooms upon this stock. True we do not secure those grand shoots from the base of the Rose which are so plentiful among the pure dwarfs, but if we get less wood with better finished blooms the benefits are about equal. For Teas and H.P.'s of a drooping tendency these dwarf or half standards are admirably adapted. I am by no means a lover of these bashful Roses, hanging their heads and hiding their charms until touched under their chin and forced to look upwards. They also catch the dirt from showers of rain whatever style they may be grown in; but this evil is got over to a great extent by cultivating them on the short-hedge Briers. However, one point in their favour must not be omitted; if dirt arising from heavy storms soils them when grown as dwarfs they escape the injurious hattering that the colder and more upright varieties are subject to.

THE TEAS AND NOISSETTES do remarkably well as short standards of one and a half up to two feet, so, too, do such climbers as *Maréchal Niel*, and it is usually a long time before that mysterious disease, canker, affects this variety when growing on what I shall henceforth style the foot Brier. Very many of our successful exhibitors grow the bulk of their plants upon this stock, a point which speaks for itself. Some of the more delicate varieties are different Roses when grown upon the foot Brier, while it is very unusual to find the plants cankered at the base, or with unpurified wood at the end of the season as an

generally be found upon dwarf Teas and late-growing H. Perpetuals. Louis Van Houtte, Horace Vernet, Duchess of Bedford, and many others of similar growth have been splendidly exhibited during the past season, and will naturally be ordered by many who do not know their habit of growth. Being weak, or at the best of uncertain vigour, these varieties are altogether unsuitable for cultivation as standards, but will thrive much better upon the foot Brier. No Rose without a vigorous constitution can draw its nourishment through the length of a three to four-foot Brier, and it is only courting failure and consequent disappointment when such varieties are grown in this form. R.

THE KITCHEN GARDEN.

FORCING SEAKALE.

TO OBTAIN the earliest supplies of Seakale in a very simple way. Two boxes, each 2 feet square and 18 inches deep, are provided, and 6 inches of soil is put in the bottom. The crows are

A head of "Forced Seakale" properly cut.

especially grown for the purpose in rich soil in one of the quarters of the kitchen garden, and to have them in proper condition for forcing I lift them about the middle of October and place in the earth again. If this were not done the plants would retain their green leaves for some time longer, and then they would not force so readily. By allowing a month between the time of lifting the crows and their being placed in the boxes, I find the roots obtain all the rest required. About the middle of November one box is placed in a temperature of 60 degs. where it remains, and the Seakale is fit for cutting in about a month. At intervals of a fortnight other boxes are taken to the house, and by this means a constant supply is kept up until I commence cutting later on from plants that are forced on the ground. The great value of forcing in boxes is that when the Kale has grown sufficiently the boxes can be removed to a cooler place, so that if the produce is not wanted for immediate use it may be kept fresh for a week or two if desired. In many gardens it is the practice to take up the roots and force them in Mushroom-houses and similar places all through the season. But after the beginning of the new year I like the old-fashioned plan of placing pots over the crows. When forced in this manner the produce is, I think, of better flavour. Cutting Seakale is an important matter, and the heads should be removed as shown in the annexed illustration. J.

4993.—**Storing Turnips.**—Take up the Turnips before injured by frost. Cut off tops and pack in sand in a cellar, or take up with tops entire and bury the bulbs 6 inches deep in a trench, leaving the top sticking out.—E. H.

4976.—**Badly coloured Beet.**—I have never grown the variety named. It may be badly cultivated, and is too large and coarse or too small in consequence of the hot summer. There is something wrong either in the variety or the culture, or the soil has not suited it. The information given is meagre.—E. H.

PROTECTING VEGETABLES.

WITH the return of frost kitchen gardeners must be on the look-out lest their crops get caught by the dread enemy of vegetation, and rendered useless after all the toil and care bestowed on them.

CALIFLOWERS of the Autumn Giant and other kinds now coming in fit for use need looking over every few days, breaking down the foliage over the heads until nearly fit to cut. Then lift the plants and either place them under cover out of reach of frost, or lay them in closely together out-of-doors where snails and litter can be easily applied.

CELERY keeps safely if well moulded up; but a covering of litter placed over the tops of the ridges keeps the frost from penetrating, and lifting is much easier done.

CARROTS are never better than when freshly pulled from the soil, and if any were sown at midsummer they will be much more tender if left in the soil than if pulled up and stored in sand or any other covering; but to get them out of the soil readily during frost a good covering of litter must be placed over the bed as soon as frost begins to penetrate.

TURNIPS of the white kinds, although hardy enough to withstand moderate frost, will not do so if fully exposed to freezing right through, and it is a good plan at this time of year to pull up the roots and lay them in trenches, covering the roots right over with soil, but leaving the tops exposed, and the flavour of the roots will be much superior to those stored under cover or to those left exposed to the full action of frost. J. G., *Hants.*

4927.—**Early Tomatoes for market.**—I should say that it would be quite soon enough to sow your Tomato-seed in March. Keep the plants always in a state of healthy growth. I find that I get just as early crops from seeds sown at that time as if sown earlier. It is also of much importance (if you want an early crop) to sow a variety that will stand the heat required to bring it on without drawing or growing long jointed. I have grown for some years a variety which I have never seen surpassed for earliness and productiveness, combined with good quality. It is of medium size, good colour, and, I think, the best flavour of any Tomato I have grown. I get it from seed supplied by Messrs. Cannell, of Kent. The variety I ordered was *Horsford's Prelude*, and out of the plant from that seed I found one that had larger and better-looking fruit than the rest, so I decided to save the seed, and I have found it to be the best for early work, and always commands a better price than any other. I grow this year a house 4½ feet by 12 feet of this variety, the fruits of which sold at 1s. per lb. A market grower at Harrogate intends to plant 1,000 plants in one house next year, he having tried it with success this year.—H. DUNN, *Harrogate, Yorks.*

4972.—**Compost for Tomatoes.**—Tomatoes will grow in any good soil fairly manured. One of the best crops I ever had was from a piece of newly-trenched ground under a glass roof, manured with an old Cucumber-bed just before planting, and mulched with same material when the bottom trusses were set. Leaf-mould will do for mulching, but something stronger which contains more nutriment will be better.—E. H.

—Tomatoes do not require a very rich soil to grow in. If much manure is added before or when planting them, they run away too gross and strong at first, and do not set or fruit well. The best material to plant them in is good, sound fibrous loam from an old meadow or hedgerow, mixed with a fourth or fifth of burnt earth, and a sprinkling of superphosphate, or, better still, of Thomson's manure. If the loam is at all heavy, you may add a third or fourth of leaf-mould, but I should keep the manure, and use it as a top-dressing, mixed with an equal quantity of loam when the plants are in full bearing. After the plants have fairly begun fruiting, they may be fed liberally with liquid manures, guano, ammonia sulphate, rich top-dressings, and so forth, with great advantage.—B. C. R.

4961.—**Cucumber plants for sale.**—The plants should be grown in such the same way as if to be planted out and fruited at home, but when growing specially for sale it is

necessary that they should be extra well hardened before being sent out, or the journey and probable exposure to cold air will impart such a check to plants taken straight from a warm, close house as they may never recover. Sow the seed six or eight weeks before the plants are likely to be required, placing it by preference singly in small (thumb) pots, and using a light rich compost of loam and leaf-mould, or very old and well-rotten manure in nearly equal parts, with plenty of sharp sand. Plunge the pots in a hot-bed at 75 degs. to 80 degs., with an overhead temperature of 5 deg. or 10 degs. less, and unless the bed is already close to the glass, move the pots up well into the light directly the seedlings appear. When strong enough, and the pots getting full of roots, shift them into 3½-in. or 4-in. sizes, using the same compost, but making it firmer than before. Water must be given freely, and a nice moist atmosphere be regularly maintained. If necessary the plants may be shifted on again into 5-in. or 6-in. pots, but take care to handle them off well before sending out. I have always found Cucumber-plants sell best either early in the season—in February and March—or later, towards the end of May or the early part of June, when people are clearing their houses and pits, and want something for a summer crop.—B. C. R.

Sow the seeds singly in small pots, and plunge in bottom near glass. The plants so raised should be sold, if possible, as soon as they have made one or two rough leaves, otherwise to keep them mowing on they will have to be shifted into 4-inch pots, and this adds to the cost of carriage. Plants in small 60's if carefully packed can be sent safely by Parcels Post. They may be packed as follows: Envelope the pot in warm, dry Moss, tying it round with matting. Place one stake to the plant in the centre of the pot, and tie the plant to it. Then place four stakes round the sides of the pots, bring them over the plants at the top, and secure them together. Run some soft matting round the stakes from bottom to top, and place a covering of paper over both plant and pot, and tie firmly. A dozen plants might be packed in a moderate sized box, as they may in any way without taking any harm. Boxes are warmer than baskets for packing, especially for sending long distances.—E. H.

1893.—Potatoes in a house.—Fifty-five days, night temperature will be high enough till the days begin to lengthen. The house should be a light one for potatoes. Earth up the plants as they grow to keep the stems erect as long as possible. Give liquid-manure about the time the tubers begin to form. Give air freely when the weather is suitable.—E. H.

CABBAGES AND THEIR CULTURE.

At one time we seldom could prevail upon the cook to send any kind of Cabbage to the dining-table, though Brussels Sprouts were, during the winter and early spring months, in great demand; now, however, the latter are rather despised and Cabbage is in favour. This change has doubtless been brought about owing to the short-lived admiration of coarse, strongly-flavoured sprouts; while the Cabbages of recent introduction are decided improvements, as far as quality is concerned, on the older sorts. A small, quickly-grown, and not too closely-packed heart of Cabbage, at any time during the winter or spring months, is really superior to any kind of winter green vegetable, not even excepting Broccoli, and I am glad to find they are now better appreciated by all classes of society than formerly. There are several small, or comparatively small, varieties to choose from, either of which will be found more profitable, and certainly of a better quality than the much coarser sorts that used to be thought best for autumn sowing. Ellam's Early Dwarf is of quick growth, fairly hardy, and of superior quality. Reading All Heart is quite a little gem, and we have good reason to be well satisfied with Veitch's Matchless. Wheeler's Imperial, if supplied true to name, is scarcely so tender and mild in flavour as Ellam's, but, on the whole, is yet one of the most reliable small sorts that can be grown. It is very hardy, and I had it good throughout last winter. At least two or three varieties ought to be grown, as it sometimes happens that the season that suits one may be unfavourable to another, and by growing several varieties, some of them are almost certain to be

extra good. If larger sorts than the foregoing are needed, the well-known Enfield Market, Heartwell Marrow, and some of the Drumheads may be grown, these under good cultivation producing very fine, tender heads. A good type, Dwarf Drumhead, is here figured. Other good Drumhead Cabbages adapted for market work are Early Drumhead, Dax Drumhead, Quintal Drumhead, Early Dutch Drumhead, and the Hundredweight, or Mason's Drumhead Cabbage. Such are best for the market, but they are too large for home consumption, and, besides, they form too many leaves to be profitable. The

GROUND BEING WARM, the seedlings will grow rapidly, and instead of making our first sowing early in July, it will be about the middle of the month before it is done. In colder seasons, or in late localities, we would sow seed early in the second week in the month, and again at the beginning of August. It is always advisable to sow a second time, say at about an interval of fourteen days. Some seasons the early-raised plants are apt to bolt, or run to seed prematurely, and, consequently, if no second sowing had been made, a general failure would be the result. Raise sufficient early plants to fill half the proposed bed, and complete the plantation from the second sowing. If one batch fails, complete failure will yet be avoided, and if both the well so much the better, as a long and acceptable succession will be secured. For the seed-beds I select a good open spot, a free-working soil being preferred. The weather and ground being dry, the latter is well watered a few hours previous to sowing, after which it can be raked down finely. It may be again moistened, then if the seed is sown thinly broadcast, and covered with fresh, fine soil, the moisture will ensure a quick and even germination. If kinds are troublesome, they may be kept off with fish-nets, branches of trees, or lines of cotton strained a few inches off the surface of the ground. It is not advisable to water the plants in the seed-beds until they are ready for transplanting. Then, if the ground is hard and dry, a heavy watering given a day or two previous to drawing them will start the growth of fresh root fibres, and facilitate lifting without giving a severe check to the plants. Few need to be told that Cabbages well repay for

GENEROUS TREATMENT—in fact, if grown on

as soot, lime, salt, singly or in mixture, and not infrequently some kind of artificial manure is also given. In all probability the Onions do not half exhaust this liberal supply; at any rate, there is always abundance kept in the soil for the next crop. As before stated, firm ground suits Cabbage, and all that is necessary, therefore, is to hoe over the surface of the bed and clear off the weeds. Drills about 18 inches apart for small, and 2 feet apart for the larger sorts may be drawn with a hoe, and the plants put out either with a trowel or dibber, according to the size of the ball of soil and roots. They ought to be sturdy stuff when put out, be firmly planted, and, if the weather is dry, watered in. We dispose the small sorts about 12 inches apart in the rows, but if they were hit to give second or third crops of hearts or greens, they would be allowed another 6 inches. Sometimes an old Cabbage bed is found very profitable, but we find fresh or summer-planted breadths of Caldworts superior in every way, and these do not rob the ground so much. They are planted 1 foot apart each way, and usually in succession to the autumn-sown or Tripoll Onions. Before the young plants are far advanced they are lightly mulched up, this both stealing and protecting them. If we wanted extra fine heads early in the spring, the furrows raised by moulching up the plants would be filled occasionally with liquid-manure, this soon getting extra rigour into the Cabbages. It should be remembered that firm and ground is usually much the warmest during the winter. Being naturally drained, the worms contributing to this, it is much less liable to become saturated with moisture, and is warmer in consequence. We are not troubled with

CLEANSING OF THE ROOTS, but this disease is frequently prevalent on light lands. The best preventive in the case of old gardens is trenching, and plenty of soot and lime well stirred into the surface of mowing ground is beneficial. A dressing of gas-lime applied in the autumn and well forked into the surface has been found a remedy for chalking; but this has to be on the ground several months before Cabbages or anything else can safely be put out. If this is used spring planting must be practised. If the disease is not very widespread, the plan of trenching off the knotted roots from the plants when drawn from the bed and then pulling the

OUR READERS' ILLUSTRATIONS: Cabbage "Dwarf Drumhead." Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Norman Blake, Bedford.

poor ground they are almost certain to be slow in growth and tough when cut. A loose rich soil favours rank growth, and this again is objectionable. No better site for a Cabbage bed than the ground just cleared of Onions can well be found. This is almost always very freely manured, and deeply dug, and in addition receives one or more dressings of such fertilisers

remaining roots in a mixture of clay, soot, and lime, will sometimes cure it. M.

1874.—Good loam.—A really good loam for potting purposes should be fibrous—i.e., have in it the decayed roots of the Grass which grow upon it. The best loam (turf loam) is the first 2 inches of an old and well-mended pasture.

This is pared off in a similar manner in turves for turves, stacked up with the Grass side downwards, and allowed to stay for at least a year. The more is the ideal turfy-loam, the use of which is easily recommended, but which is very expensive and difficult to obtain, except in a few favoured instances. "Constant Reader" will find the mole-hills, mixed with more or less leaf-mould and sand, according to the purpose it is to be put to, and also the nature of the loam, will make a good compost for general purposes. Mole-hills and decayed vegetable refuse, or the remains of an old hot-bed, with the loam, will also be very useful.—P. U.

— Although good loam can be found in many parts of the country, there is generally a difficulty in getting it, and, as a rule, gardeners on the estates where it is to be found are the worst off in this respect, as they are not allowed to get it. The best loam is that of a fibrous character, which generally may be found in public commons or on hill sides. Ordinary turf rotted down and mole-hills used with it in equal parts, with a fair sprinkling of sand, will make an excellent compost for general use in the garden.—J. C. C.

— Loam may be roughly described as a virgin earth of a more or less alluvial character, and yellow, red, or light-brown colours. It varies from nearly pure sand on the one hand to clay on the other, but the medium is best for most purposes. Loam of fairly good quality can usually be found in most districts, and the best is that from an old pasture or meadow, cut about 4 in. thick, and laid up in a heap until the Grass is dead. It is then full of decaying fibre, and with a little rotten manure or leaf-mould will grow almost anything.—B. C. R.

— Good loam is the top 4 inches, including the turf, of an old pasture where cattle and sheep continually feed. Mole-hills do not come under the gardener's idea of good loam; the gardener wants the turf and the fibrous roots to enrich the soil as they decay. There is nothing of this sort in the mole-hills.—E. H.

ORCHIDS.

CYMBIDIUMS.

I am asked to say a few words about these Orchids by several readers, some mentioning one species and some taking another, so that I may take it as an indication that these plants are becoming extremely popular, and so it is well for those who have these plants under their charge to ask for what information they require now early in the season before they begin to flower. I will therefore devote some of my space to reviewing the various showy kinds of the genus. Some few of these, however, I omit because I think they are too scarce and too expensive to be in the hands of the readers of this paper; but the kinds here named are of surprising beauty, and they are, moreover, easily managed, mostly requiring cool treatment. There is one thing, however, which I would warn my readers against in the cultivation of these plants, and that is to guard against giving them too large a shift. There is another thing because they thrive in more solid earth than many kinds of Orchids that they will, therefore, take a mixture of manure, and I have seen plants that were so treated a few years ago which have been getting smaller ever since, and they have never flowered half like they did the year before this manure took place. The Cymbidiums are all thick-rooted plants, and as they root very freely they require ample space for them to spread in, with a fair amount of soil, so that they are not disturbed every season. Many of the kinds come from considerable elevations, say some 5,000 feet or 6,000 feet or more, and these require cool treatment, but others are more tropical kinds, and need more warmth; but I will indicate these when describing them. Good drainage must be given them all, and the soil should consist of good turfy loam, fibrous peat, and leaf-mould, to which may be added some chopped Sphagnum Moss and some sharp silver-sand, pressed firmly down, and not raised above the pot's rim, which admits of the plants having a better supply of water to their roots, and this they must have, but at the same time the surplus quantity should be carried quickly away, and not be allowed to stand and stagnate about the roots. The temperature should be about as cool as that of

the Cattleya-house in the winter months, and in the summer-time the heat of the Odontoglossum-house will be all that they require, differing, however, from the Odontoglossums in liking good exposure to sun and light.

C. BRANTLEY.—Of this plant I have a flower from "G. T.," asking its name and its treatment, the first of which I have given, and it is a very good form of the species, being large, over 4 inches across the sepals, and petals being of a yellowish-green, streaked with lines of reddish-brown, the lip being much blotched and spotted with red. It always blooms at the latter end of the season, the flowers lasting long in perfection. This Orchid comes from Sikkim and Nepal. It is a mountain plant, and grows at about 6,000 feet elevation, but it does come lower down. The temperature already indicated suits this plant well. It likes an abundance of moisture during the summer months, when it does not in any way object to strong heat. It must be also borne in mind that these mountain-plants require plenty of air. Indeed, to stifle these plants up as I have seen them done, appears to me to be the very worst system for these and any other Orchids, and its persistence in is sure to lead to failure and disaster. Therefore I say, be sure to have these plants well ventilated.

C. LOWIANUM.—"C. D.," "M. G.," and others that have sent in a request about this plant will find them all answered in the following lines, and those of my readers having plants sufficiently strong to flower will now begin to see them pushing up their spikes. These continue to grow for two or three months before attaining their full size, when their flowers begin to open, and they continue to display their beauties for some three or four months longer. This plant was sent home by my old friend Boxall to the Messrs. Low, of Clifton, for the first time some sixteen years ago, and those having any unflowered plants of it must look out for their blooming, for from amongst them may spring up another grand type of the fine C. Tricorymum. The only plant which has yet flowered came from a batch of C. Lowianum, and from which it presented no appreciable difference, but when in bloom it is a grand and beautifully distinct kind, and it is a very valuable plant. The only specimen I have seen of it at present is the plant which exists in the collection of the Baron Schroder, and which came out of my friend Tracey's collection at Trichenham. This C. Lowianum varies somewhat in colour, the most distinct being the variety which is named C. Mauldinum, the sepals and petals of a pale apple-green, and the lip is bright yellow, white at the base, very distinct, and a striking contrast to the normal state of the plant, which is very beautiful and showy, having a long stout raceme, bearing from one to four dozen of its large flowers, each measuring nearly 4 inches across, the sepals and petals being greenish-yellow, streaked more or less with deep reddish veins. The side lobes of the lip, which stand erect, but which do not enclose the column, are light yellowish-white; the middle lobe is white at the base, and the front part stained with a rich deep-violet-crimson with a pale, narrow marginal border. These, as before remarked, last several months in full beauty. This plant forms a beautiful large specimen for the centre of a house, and now it is showing up its spikes it should be given a slightly warmer atmosphere, and it may have also a little more water than has been given them for the last month or two.

C. DRONANUM.—"H. H." says of this fine species he has a plant, bought at the sale of M. Seegar's collection, but now he doubts its being the true kind, only because the plant is growing well, and he hopes it will flower? Well, it may do so, as the plants sold at that sale were strong and in good condition. The plant is a broad-leaved, dwarf-growing one. It makes pendent spikes of bloom, which are from a foot to 18 inches long; the flowers are numerous, and about an inch and a-half across; the sepals and petals are soft green, with dotted lines of deep-purple; the lip is deep-crimson, having a large spot of deep blackish-purple at either side near to the throat. Although not so showy as those previously named, it is a very handsome species, and until the present season it has been one of the rarest in cultivation. This plant likes to be grown in good peat-fibre, and it also likes the temperature of the Cattleya-house. It comes from Northern India.

C. EBURNUM is a beautiful species, having narrow leaves of a deep bright-green. This obtained the name of a bad grower and a shy bloomer, but this came about through bad treatment in keeping it both too dry and too hot, and so in my young days it was quite an exceptional thing to get a plant with a few blooms upon it. Now, however, it is treated more rationally and cool, never letting it become dry. It grows exceptionally well, and flowers profusely, so that we have here a large pure-white, waxy flower, which measure some 3 inches or 4 inches across. These are also very fragrant, and last long in full beauty. There are one or two varieties of this plant, differing in being more or less spotted. This comes from about the same altitude as the previously-named kinds, and thrives under the same conditions.

C. THURSONI.—In this we have a very different plant. It comes from Barmah, but although from this warm part of British India, it comes from about 6,000 feet altitude, and so it comes into about the same category. It is just about thirty years ago since this plant was received by Messrs. Low, of Clifton, from the Rev. Parish, and a few years since I saw it in the very best state I have ever seen it with Mr. Shuttleworth, in his nursery at Clapham-park. The flowers are borne about four or five together; these are green, more or less spotted with reddish-brown; the lip yellow, streaked with reddish-brown.

C. MASTERSI.—This comes very near to C. eburnum, and, indeed, it has the appearance of that plant very much when not in flower. This plant was found by Griffith, nearly sixty years ago, so that the plant is well known in British gardens. It occurs in various parts of Northern India at some 6,000 feet elevation. It flowers in the autumn months, bearing a short raceme of white flowers, with a yellow throat, and these have a delightful fragrance. Some forms have a beautifully spotted lip, and these have received distinctive names, but all have thin flowers in short racemes.

C. ELEPHANS.—This plant is the one which the genus Cypripedium was established; but there is not much difference in the plants that are put into it. It was found in Northern India about the same time and in the same place as the previously named plant. It produces dense pendulous spikes, the flowers being of a pale yellow, but not fully opened. This has been a very rare plant in our collections; although introduced nearly sixty years, it has not been cultivated to my great extent. Beside the above there is the old C. penhulm, which is figured in Curtis' Botanical Magazine in 1797 under the name of Epidendrum albidum. Another is C. grandiflorum, C. Finlaysonianum, and the variety adnatum. C. Hookerianum, which I really do think is different from grandiflorum. All these plants have fine flowers, and are well worthy of a place in every collection. MATT. BRAMBLE.

CELECYNE GARDNERIANA.

I AM in receipt of some flowers of this elegant and somewhat rare plant from "John Jenkins," asking if I can tell him how to manage it after flowering? Well, I will try to tell him all I know about it. I had the plant growing with me through the fifties and part of the sixties in some quantities, when it was considered quite a rare Orchid. It was found originally by Wallich, but it was left to my old friend Gibson to first send the plant home to our gardens, and Paxton flowered it at Chatsworth. The spikes are pendulous, and the flowers are prominent, purest white, stained in the lip with pale lemon-yellow. It lasts long in full beauty, and when it is just flowering it should be hung up in the Cattleya-house, and be well exposed to the light, and this plant should be kept moist, and it should never be allowed to become quite dry. It should be potted in rough fibrous peat and Sphagnum Moss. The pot or basket in which it is grown must be well-drained, and the soil should be made up into a mound above the rim, and kept fairly moist all the year round. This plant likes plenty of sun and light, but yet it requires to be shaded from the sun when it is too strong. It likes the warmth of the Cattleya-house, but after the growing season is done it should be moved into the warm end of the Odontoglossum-house, and after the flowering season is over the plant should be put into the Cattleya-house, and not started into growth until the spring. MATT. BRAMBLE.

OUTDOOR PLANTS.

SINGLE PÆONIES.

THE PÆONIES have been exhibited in excellent condition at the metropolitan flower shows this year, the double varieties of *P. albiflora* being numerous and very good, and the colours of the most varied kinds. Some of them are deep purple, purple-crimson, crimson, carmine, pink, delicate rose, bluish-white, &c. Amongst them the single forms of this species were very attractive to the visitors. They were distinct in character from the double varieties, and are certainly more elegant. The many species now in cultivation in our gardens form a noble and distinct feature in May. I grow thirty-three species and varieties of species, but this being a rather late season they were not fully in flower until the last week in May. Although not much known at present in English gardens, they were cultivated many years ago, and some of the prettiest of them have been longest known. *P. tenuifolia* is a very elegant plant with finely divided leaves, distinct from any other. The large crimson flowers with yellow stamens are very striking. It is stated to grow "naturally in the Ukraine and about the precipices on the borders of the Volga," &c. The first to

from wet. In my garden it stands well enough. *P. Emodi* was next in order; it has large cream-coloured flowers with golden anthers. It is said to be more tender than any other species, being a temperate Himalayan plant from Kummou to Cashmere. *P. triterinata* has flowers of good form, rose-coloured. This is distinct both in leaf and flower. *P. peregrina* compacta and *lyzantina* also flowered with this group, and are distinct from the species. All the above flowered the last week in May and up to the 6th of June, when the following were noted: *P. humilis*, a dwarf species with rosy-purple flowers and yellow stamens, the plant dwarf and compact; *P. Wittmanniana*, creamy-white, very distinct. This was said to have yellow flowers, and was introduced so long ago as 1842. It was discovered by a certain Count Worouzzoff in Alaharia. Dr. Lindley also stated that 25 guineas were demanded for a plant of it. Broteri had rich-crimson flowers with yellow anthers, the plant dwarf and distinct. Brownii is very distinct; it is planted on the rock garden, and is a neat-looking little plant, but so far I have failed to flower it. *P. Russi* has well-formed crimson flowers, with a mass of bright-yellow anthers; the leaf and plant distinct. The true *P. albiflora* and varieties *laciniata* and *rubescens* flowered freely, and are

4600. — **Plants for a herbaceous border.**—I would recommend the following as all being good hardy free-flowering plants, and of about the average height you mention: *Achillea ptarmica* alba pl., white free-flowering, one of the most useful plants grown; *Anemone japonica* H. Jolbert, white, and *A. japonica*, rosy purple, universal favourites; *A. fulgens*, dazzling scarlet, handsome; *Matricaria inodora* pl., white; *Scabiosa caucasica*, lovely pale blue; *Dianthus Napoleon III.*, bright red, pretty; *Gypsophila paniculata*, white, an extremely elegant plant, fine for bouquets; *Lychnis chalcidonica*, fl. pl., fine bright scarlet; *Chrysanthemum maximum*, white, fine; *Dielytra spectabilis*, pink, one of the finest herbaceous plants; *Trollius europæus* (Globe-flower), yellow. *Papaver orientale* (Oriental Poppy), scarlet, with black spot; *P. nudicaule* (Iceland Poppy) orange-red, white and yellow, great favourite, fine for cutting; *Coreopsis lanceolata*, yellow, very showy; *Rudbeckia speciosa*, yellow, black centre, very handsome. *Campanula carpatica*, blue, and alba, white; *Centauria montana*, blue; *Antirrhinum filiastrum* (St. Bruno's Lily) elegant spikes of pure-white flowers; *Aquilegia glandulosa*, blue and white, fine; *Spirea palmata*, rosy-crimson, one of the most beautiful hardy plants in cultivation; *Yucca filamentosa*, tall spikes, covered with white flowers, noble appearance. — E. J. P.

4917. — **Japanese Anemones.** — The present month is a good time to plant the above in your garden. They are exceedingly handsome plants either for borders or rockwork, and where cut flowers are required for house decoration are most useful, the white variety (*A. jap. Humorie Jolbert*) being a most profuse bloomer, and specially adapted for this purpose. *A. jap.*, with its large red flowers, and *A. jap. elgicus* (rose) form a nice contrast to the above. — E. J. P.

4962. — **Planting Gladioli.** — There are several sections of Gladioli, early and late flowering forms, some species, but the majority beautiful hybrids. The time to plant is sprig—ray, April—not now, as Gladioli are not really hardy, and frequently get killed in the winter months when the position is very favourable. Gladioli are best when planted amongst such things as Dahlias, although if there is space a bed of *G. breucheyensis* makes a brilliant picture in early autumn. The soil must be well prepared, and the bulbs put in bold clumps. Good turfy loam is the best soil, and at this time the bed or soil in which the bulbs are to be planted in spring should be thoroughly well dug up, and plenty of old hot-bed manure incorporated with it. — C. T.

— Plant Gladioli in March and April. A good loan enriched with old manure will grow Gladioli well. — E. H.

LIFTING AND REPLANTING HARDY PLANTS.

FINE weather without frost in November gives the hardy plant grower the chance of going through the stock, lifting, dividing, and replanting where necessary; but it is not wise to lift everything in the borders and to manure and dig the ground all alike, for some plants are better left untouched till spring, others resent frequent disturbance, while others again do not need it, and all vary in the amount or kind of manure they want; some will assimilate a large quantity and some are better without any. When this is borne in mind it will be seen that any attempt to treat all alike would be folly, and that the better way will be to decide on the proper site for each plant. After Carnations are planted no time should be lost before commencing the work, and in some cases it would be even better to take it in hand earlier if possible. First, attention should be given to those things which are intended for naturalising in out-of-the-way places, which cannot easily be got at in bad weather, as by leaving these till last a serious loss is often lost, or the plants have not a fair chance of establishing themselves. This question of naturalising requires much fore-

A Single Peony (*P. Wittmanniana*).

flower with me was *P. peregrina*, another crimson-flowered Levantine species with large bold leaves, but not so striking as those of some kinds. It was cultivated by Miller, and also by Mr. Salisbury at Brompton. The next to open its flowers was *P. decora*, not the most handsome species, but the flowers were a distinct purplish-rose. The downy leaves of *P. mollis* are distinct from those of any other Peony; the flowers deep-purplish-red; anthers bright-yellow. *P. aretina* and *P. aretina Baxteri* are two good sorts; the first has rosy-crimson flowers, and the variety *Baxteri* crimson; they flowered about the same time. The common *P. officinalis* in its single state was very pretty, the flowers being of a rosy tint, the petals rather crumpled. This plant was cultivated in England as long ago as 1548. In Parkinson's time single and double forms were cultivated. The variety *anemoneiflora* flowered with me also. In this variety the flowers are purplish-crimson, and the yellow stamens are replaced by numerous purplish filaments. The plant has been sent from a certain Prince de Salin Dyck about 1830. *P. anomala* came next in order; the flowers crimson, set off by lanceolate leaves. It is not very striking as a garden plant, but interesting as a distinct form, and it is termed the jagged-leaved Siberian Peony. It is stated to perish in gardens in winter, not from cold, but

the most beautiful amongst the single Peonies. They are all very easily grown, and I do not care to rot them up in pots; even the little *P. Brownii* takes its chance out-of-doors. The border where they are growing has been deeply trenched and well-manured. Some decayed manure was also placed on the surface during the winter, but even this is not necessary, as they seem to be all perfectly hardy. They need only to be left alone and will in time grow into large specimens. J.

"4878. — **Outdoor plants.** — In my own practice I like to get as much of this work done in autumn as possible, because it eases the spring work, and it is an advance, especially in the case of spring or early summer-blooming plants, to get them established before winter sets in. Then, again, in the average herbaceous border there are bulbs of various kinds, and it is better to move these in autumn, than wait till spring. When borders are rearranged and manured it is not always possible to get the replanting done before Christmas, and then it will be as well to wait till growth becomes active, say in March. — E. H.

Lime and coal-ashes. — Ashes and lime are useful to open up heavy land. Put ashes and stable-manure on your beds in the land up roughly, and let it lie for the winter. In the spring, just before planting the crop, give a dressing of lime and fork it in. — E. H.

thought, and if this is not given failures will be more frequent than successes, for there are many things to look at in planting in places which do not often come under the eye, and there are many enemies to contend with unless one wishes to court failure. There are not many effective plants grown in the majority of gardens which can be naturalised successfully and allowed to take care of themselves for any length of time, and if plants outside the limit are chosen, the grower must be prepared to devote some time to keeping the groups free from weeds at least. Bulbs of most kinds should be planted at once if this is not already done, for the sooner they commence root action the finer the flowers will be. Irises are all impatient of removal, and must be left alone if possible; but when planting is imperative, early autumn is the best time to do it; this sometimes saves a year in the time of flowering, though little must be expected of them for the first year. Some of the Helianthus occasionally get killed in a severe winter, but I find that divided pieces often escape when established clumps suffer. Anemones are best done soon after flowering. Anemone japonica alba I have found grows better when autumn-planted. This plant acts very differently in some soils to what it does in others, for sometimes it becomes a troublesome weed, but in light sandy soils increase is very slow and it never gets out of bounds. Alliums, such as A. Moly and A. neapolitanum, may be broken up and replanted now if necessary. Asters (Michaelmas Daisies) and Doronicums enjoy frequent division and plenty of manure. Many of the Campanulas are better for breaking up, replanting only the strongest crowns. Chrysanthemum maximum, the perennial Centaureas, Geums, Mertensias, perennial Poppies, Monardas, and many other things well repay attention, and in our light soil I find that some plants generally supposed to do best when divided in spring, such as Delphiniums, Phloxes, Trachelium, and Plumbeago Larpentae, do equally well when autumn-planted, and are well out of hand before the spring comes upon us. J.

CHRISTMAS ROSES.

The Christmas Rose is a good plant for the smaller gardens. It is a familiar flower by name, but not often seen grown well, as it likes a rather damp, shady position, which cannot always be given. A variety of *Helleborus niger* named *maximus*, and is known under several synonyms as *major*, *gigantens*, and more commonly *altifolius*. It blooms earlier than the type, opening its large white flowers in November, and both leaf and stem are mottled with purple. This kind and St. Bridget (white) are the best of the many kinds in cultivation, not forgetting the type. If there is a little ditch in the garden, the sides shingly and moist, establish the plants there, and they will develop into broad, leafy clumps, a pleasure to look at even when flowers are absent. If to be planted in the border, let the soil be of a good, light, bony character, and not likely to get stagnant, as, although Christmas Roses want moisture and partial shade, they will not grow in water-logged spots. Another place for them is by the margin of shrubberies, if the soil is not exhausted by the shrubs. Where a small quarter is set apart for getting flowers for cutting, the plants should be covered with a bell-glass when the buds are coming on, and the bloom will be earlier and purer than if they were in full exposure. Another way is to pot them, and a few patfalls in the greenhouse are enjoyable, as one cannot always go into the garden; the flowers, too, in bad weather, getting much sullied, unless the clumps nestle safely in the more sheltered spots in the rockery. Large specimens, either put into baskets or piled up with light soil or Cocoa-nut-refuse, will, if placed in gentle heat, provide a splendid lot of flowers, and so pure that they can be used in the choicest decorations. They must not, however, be too much excited into growth, nor directly they are past their best placed out where they are likely to suffer from frost. Hardy plants of all kinds do not relish artificial heat. The *Helleborus* after being forced, so to say, this year, should be left alone next, as they cannot stand being lifted and potted every year. Christmas Roses are not difficult to propagate, and may be raised by seeds or from

division of the roots. The best way for amateurs who only want a small increase of stock is to propagate by division of the roots. The place in which they are to be planted must be well prepared, and the crowns divided with a sharp knife. The time for this is the spring, and during the ensuing summer give ample supplies of water, also mulching with Cocoa-nut-refuse or well rotted horse-manure. V. C.

TREES AND SHRUBS.

WEEPING TREES.

GRACEFUL in outline, elegant in growth, impressive and attractive in appearance, weeping trees possess all those characteristics which render them especially valuable for the embellishment of landscape, park, and lawn. This peculiarity of form among weeping-trees is a precious one, inasmuch as the contrast between the rigid upper portion of the tree and the pendulous outer and lower parts forms a very striking and attractive feature, quite distinct from the aspect usually presented by other trees. But for all this they require to be employed discreetly, or the good effect which they are capable of producing is destroyed. They should be planted sparingly, and not near one another, and carefully selected and suitable sites must be chosen for them, or half their charm will be lost; when met at every turn or too often repeated their interest and attraction are greatly diminished. They

Weeping Ash at Cawdor Castle.

should never form large groups or masses, nor be mixed up with other trees in belts or borders. In the hands of a skillful planter they are capable of producing the most charming results, and are more effective in giving character and expression to a landscape than any other trees. The Weeping Ash (here figured), as is well known, is a tree of great beauty, and so is the

WHITE-LEAVED WEEPING LINDEN (*Tilia argentea pendula*), which is a handsome, drooping variety, with large, round leaves of a greyish-green colour above and silvery-grey beneath. Worked upon stakes standard high the branches shoot out almost horizontally, and as they increase in length bend gracefully towards the ground, giving to the tree a decidedly pendulous character. Being a strong grower, it requires to be vigorously pruned to keep it in shape. In this way it can be trained into a round symmetrical head, and will always be found a desirable addition to any collection on account of its distinct silvery foliage, which contrasts effectively with the deep-green of other trees. G.

Pruning and clipping shrubs.—Many questions are asked in GARDENING about the best way to clip or prune shrubs, Conifers, and such-like things? This shows that much of it is done, and we know from observation that the beauty of shrubs in both large and small gardens is spoilt by the absurd long process

The fault in the first place is in planting them too thickly together, and the clipping has to be done to prevent them overshadowing everything else in the garden; but the better way is to remove one here and there to enable those remaining to develop their natural beauty. A shrub is a beautiful object, but made objectionable by clipping. Conifers when clipped are deprived of their true elegance and beauty, and when hacked about carelessly never recover their true character. In dealing with Lilacs, Weigelas, and shrubs of this kind so commonly seen in gardens, the proper way is to remove crowded-up growths to give the younger wood space to develop. The suburban amateur gardener takes, I fear, the London parks as his model, where the shrubs, as a rule, are wanting in variety, and regularly clipped in to make them uniform to a set space. They lose their natural beauty, and are a positive eyesore in many cases. Each autumn the ground about them is regularly forked up, destroying fibrous roots in the process, and the effect of such treatment above and below is to produce ugly, stunted bushes. It is unnecessary to write against Privet, Aucubas, and common shrubs being planted in gardens until one gets heartily sick of them, as lists of beautiful flowering trees and shrubs are given from time to time. Gardeners of any kind, whether in town or country, can never be made beautiful unless a good selection is made, the shrubs well planted, left alone to develop their natural beauty, and not dug amongst in the autumn. Aholish *Aranarias* from small gardens. They are rarely satisfactory in big places, and the complaints frequently made about lower branches dying off is through the soil and situation being unsuitable. — F.

4979.—**Lime-trees.**—The red-twigged Lime will flower as soon and as freely as any. Alba, the white-leaved variety, has rather larger flowers, and is about a fortnight later. It is rather difficult to say at what age a Lime-tree will come into bloom, as so much depends upon soil, situation, and other local matters; but a great number of flowers will be produced till the tree is from fifteen to twenty years old. Limes are generally propagated by layering in autumn. What are termed studs are kept in nurseries for the purpose. Studs are old plants which, from being frequently cut back, throw up annually numbers of young shoots. E. H.

4980.—**Quick-growing Ivies.**—It is scarcely wise to give lists of Ivies, as they vary so greatly in name in different gardens. The following, however, may be recommended and are fairly accurately named in most nurseries: Emerald Gem, or Green, as it is sometimes called, is one of the finest, the plant making very rapid growth, and producing a wealth of rich-green leaves. It shoots up remarkably well, and does not get straggling or leave bare spaces in the walls as in the case of many kinds. This should be selected amongst the deep-green-leaved kinds, and if you wish for one with a very large leaf, almost as big as a plate, choose *Riegeriana* or *dentata*. It is better for planting against out-buildings than a wall. *Glyna* and *atropurpurea*, which has bronzy-purple leaves, are also very fine, particularly the last-mentioned, an Ivy which we do not see sufficiently of in gardens. Its foliage is quite of a self-purple chocolate tone, very rich during the winter months. One would scarcely believe how tender some kinds are, as *algeriensis*, which last winter I saw practically killed, the leaves browned as if they had passed through a fire. In selecting variegated Ivies carefully avoid those that make a patchy growth. *Mudicronis* variegata is really too straggling. It is not sufficiently hardy for general planting, although more used, perhaps, than any other variety. *Il. aurea elegantissima*, *Guld Cloude*, *Lees Silver*, and *variegata elegantissima* are good kinds, for the most the leaves being very distinctly and attractively coloured. Plant Ivies well, preparing the soil carefully for them, if it is bad, and through the first summer help them with liberal supplies of water when the weather is dry. The common Ivy of the hedgerows is very pretty and its leaves varied in colour, and pleasingly veined. I once planted a wall with it. It took some little time to establish, as the bits were cut from the hedge-grows, but once it obtained firm hold grew vigorously. The second year the shoots were cut down pretty closely, and the growth then made was proportionally robust. — C. T.

THE BETTER KINDS OF TULIPS.

As bulbs are now being planted, it would be well to get a few of the better kinds of Tulips in gardens—not the Dutch varieties, which are very fine, but often repeated in gardens. The flowers of the species and varieties are superb for colour, and a few clumps in the borders tell well. Such kinds as T. Chusiana are dainty Tulips, rather expensive, and rather troublesome to do well, requiring a warm soil and position. It is rather T. fulgens, T. elegans, T. macrosepala, and T. gesneriana that deserve to be well planted in gardens for their colour. T. fulgens is a tall, stately form, the flowers of deepest crimson, and T. elegans is a beautiful Tulip, the flowers very rich crimson in colour, and the single reflex, T. macrosepala (carmine), the fine T. gesneriana (often so beautiful in cottage gardens), T. retroflexa (bright yellow, with the segments reflexed at the apex), and T. viridiflora (green, with borderings of yellow) are all worth planting; but get the first three mentioned before the others, and the bright little T. persica, a very dwarf kind, the sweetly-scented flowers in the bud are of a coppery tint, but often of a bright yellow. The bulbs vary from one shilling to half-a-crown a dozen, so are rather expensive to plant freely. T. Greigi is very shiny, the flowers orange-scarlet in colour, and the leaves bold, glaucous in colour, bloomed with a chocolate gleam. It is a very expensive species, however, although introduced many years since, but it is not always satisfactory. A small bed of it on the outskirts of the lawn is showy, and the bulbs are hardy, liking a light soil and open position. The Parrot Tulips are comparatively cheap, and the quaintly-shaped flowers, coloured in a quixotic and bizarre way, are delightful, the flowers being exceedingly interesting, and the colours often the most brilliant, the segments splashed with crimson and yellow, and gashed at the margin in a curious way. One seems to lose sight of such fine Tulips as those mentioned in modern gardens; but bold clumps in the borders or beds are very beautiful in early May, or they bloom later than the Dutch varieties in May. F. C.

TREATMENT OF TUBEROSAS.

HAVING a batch of these sweet-scented and popular flowers now in bloom, and which will last well over Christmas, a few notes upon their treatment may be useful. As a general rule, these bulbs are grown in a temperature much higher than the average amateur can command, and it is very seldom that we find them well done by the unprofessional grower. There is not the least need for strong heat to secure a good batch of these flowers during late autumn and winter, and my plan is as follows: Purchase a few sound bulbs early in the year—say, January or February. Tuberosas are generally sent over in two batches, one from Africa and one from America. If we get the latest bulbs and pot them into strong, turfy soil, making them very firm, and covering the bulb a little more than half way we may secure a more even batch than is generally seen. Pot into moist soil, and place a little sharp sand at the base of each bulb. Stow them in a pit or frame, and cover with Cocoa-nut refuse. Early in March is a good time to pot. The chief cause of failure under this cool treatment comes from damp, but if the bulbs are potted into soil of a medium moistness, and covered with the Cocoa-fibre, there is no fear of damp, as water is not needed until the roots are well at work. By this time the weather will be warm and dry, and watering must be carefully attended to. Almost full exposure may be given during the midsummer and early autumn months, by which time most of the bulbs will have started their spikes. When growth has well commenced frequent applications of weak liquid-manure are very beneficial. As autumn approaches and before we get cold nights the plants should be housed, when if the forwardest be brought into a warm greenhouse as needed they will flower freely, and keep up a supply all through the winter. If there be any preference, I would give it to American-grown bulbs, as I think we get fewer failures from these. The secret of cool treatment is avoiding a cold, damp soil, and this is easily done if plunged, so as to get rid of the necessity for water until summer has arrived, and the pots are fairly full of roots.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 47, Southampton-street, Great-street, London. Letters on business should be sent in the Post-office. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by indicating, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and manure vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5004.—Reflexed Chrysanthemums.—What are the names of the best twelve varieties of reflexed Chrysanthemums for exhibition?—R. H.

5005.—Damp wall-tiles.—Will anyone kindly tell me of any solution for flies found efficacious in keeping damp out of a dwelling-house? To be applied outside.—BLACKWOOD.

5006.—Celery for show.—I shall be greatly obliged if someone will give me the names of the best kinds of Celery for show, and how ought it to be grown to have it ready in August?—H. H.

5007.—Bees and Carnations.—Will anyone inform me whether, in the keeping of Bees in a garden where Roses and Carnations are grown, the flowers will be spoiled or any way affected?—E. M.

5008.—Chrysanthemum cuttings.—Will someone kindly inform me if Chrysanthemum cuttings can be struck in a cold greenhouse, and what kind of soil is the best for that purpose?—R. H.

5009.—Seeding Brier stocks.—These have just been transplanted into the beds where they will be bedded next year. Will someone kindly state if it is necessary to cut them back at all? If so, when?—J. T. P.

5010.—Treatment of Petunias.—Will anyone tell me how to treat double Petunias which have just finished flowering to get a stock of cuttings for next season? Must the cuttings be of old or new growth?—ISABELLA.

5011.—Chinese Primulas and Dentzia gracilis.—Will somebody tell me how to grow Chinese Primulas (single), so as to get seed? Also how to propagate Dentzia gracilis, and the season for doing it?—ISABELLA.

5012.—Heating a greenhouse.—I wish to know if earthenware socket-pipes would answer for heating a greenhouse with hot water, as they will run much cheaper than iron ones? Will they be liable to burst?—W. H.

5013.—Roses in a cool glasshouse.—I have Climbing Deconino and W. A. Richardson Roses now growing in a cool glasshouse. I want to know if they are suitable for forcing with Marechal Niel, or are they summer Roses?—W. C. Bristol.

5014.—Japanese Chrysanthemums.—Will someone kindly give me the names of the best eighteen varieties of Japanese Chrysanthemums for exhibition? Also the names of the best eighteen varieties of incurved kinds for the same purpose?—R. H.

5015.—Cost of heating a greenhouse.—Will you tell me what is an average consumption of coal yearly for heating a range of glass-houses, about 45 feet long, pipes 4-inch? Half the house kept at above heat, the rest temperate. The best household coal used.—STURTA.

5016.—Treatment of a Fern, &c.—I should be very grateful if any reader of GARDENING could give me information concerning the treatment of Fern Platycoma excelsa, and also the Rock-plant Poterium sanguinolent, both of which I have just had given me?—C. M. M.

5017.—A greenhouse wall.—Is there any objection to covering the brick wall of a lean-to conservatory with rough Cork, and are there not some delicate or rather small creeping plants or Ferns that might be rooted in its crevices? Does the Cork encourage insects?—G. E. C.

5018.—Hoya and Draena, &c.—Will someone kindly tell me how to treat a Hoya and Draena terminalis? I have only a sitting-room to keep them in. Do they require much water? I should like also to know how to treat the Polystichum angulare. What should it be potted with?—E. M. S.

5019.—Treatment of Cherries.—I have some Cherries which were budded a year and a half since; they have grown well in one long rod. Should I cut it back now to make them fruitful? I want to train them for a wall. They each budded about 6 inches from the ground on Cherry-stocks.—PINK.

5020.—Plants for carpet-bedding.—I shall feel obliged if someone will kindly mention in GARDENING a few things suitable for carpeting the front of a mixed border of low growth, and evergreen (like London Pride, for instance), to plant about near Rose-bushes and amongst other things?—MRS. TAYLOR, Blackheath.

5021.—Ferns in a greenhouse.—Will Ferns do well planted in a border round wall below pipes (which will only be heated in cold weather)? What soil is suitable for them, and how to mix Lycopodiums and bulbs of Daffodils with Ferns? Would Maiden-hair Ferns grow on south side, and what sorts would be best on west?—G. E. C.

1022.—Covering for a stage.—I have three rows of 4-inch piping along the front of my greenhouses, and the stage is immediately above, but only 12 inches higher. It has occurred to me that my plants on this stage will be dried out. Perhaps someone will kindly suggest some covering for the stage? Would corrugated iron do?—EMMASTAY.

5023.—Pear-trees not growing.—Two years ago I trenched up a mallow, turned it into a kitchen garden, and planted pyramid Pear-trees; but they do not make any wood or bear fruit. Will someone kindly tell me what I ought to do to make them grow and bear? The trees have not been pruned since they were put in. The soil is sandy.—G. A.

5024.—Artificial manure.—Will someone please say what would be the best sort of artificial manure to use for flower border in small garden, into which there is no means of bringing dairy or other like manure? The flower border is about 80 feet long and 5 feet wide. Would decayed leaves be better than the artificial manure? and, if so, what is the speediest way to make the leaves rot?—L. K. B.

5025.—Growing early Rhubarb.—Having several large roots in my garden, will someone kindly inform me how to proceed in obtaining an early supply? I have plenty of leaves. Should I put them on the crowns and cover with a tub or pot, or should I put the tub on and leave round outside? Do they also want fermenting before using? Any information as to best means will oblige?—NURICE.

5026.—A bed of Lily of the Valley, &c.—I am very anxious to make a new bed of Lily of the Valley. Kindly give me directions as to soil and best manure? Also if it would do well in a sheltered spot about a yard away from an old Beech-bush? Any suggestions as to making a Carnation bed would be gladly accepted. Would rabbit-sand do? What is the best mixture for planting Carnations in?—PERRINIA.

5027.—Forcing Lily of the Valley.—Would someone kindly tell me, when forcing Lily of the Valley, how soon should they be taken out of the hot-bed, and thrown a Vine-house or a fernery till them best? I had some that have been in hot-bed a month; most of them are gone, and a little I have then plunged in a Melon-frame, which has a hot-water pipe. Would it help them to keep that hot?—EUGENIA.

5028.—Climbing Roses in a greenhouse.—How many Climbing Roses could be grown in a lean-to house of 12 feet south and 20 feet west? Which would suit best, for each aspect, and for cool corner in west? How far from glass must they be kept, and will the shadow from them injure other plants? What is the name of a good Crimson Passion-flower with drooping blossoms, and would anyone say if it is difficult to manage, and also give names of other good plants for hanging-baskets?—G. E. C.

5029.—Bulbs in pots.—Will the following bulbs—Freesias, Daffodils, Narcissus, Chionodoxas, Crocuses, Snowdrops, and Tulips—do well in pots for blooming this winter and spring, bloom satisfactorily if left in the same pots next year? I shall be very glad to hear from some of my more experienced brother readers respecting the treatment, &c. It is a matter of considerable expense to have to procure fresh bulbs every season, I may say I do not possess a garden.—KEMMIS.

5030.—Pruning and repotting Tea Roses in a cold greenhouse.—Will someone kindly give me the following information in regard to some Tea Roses now in a greenhouse which is almost entirely unheated? When should they be pruned? When should they be repotted or their roots otherwise attended to? When should they be stood out-of-doors? When should they be taken in again? The Roses have been blooming freely in tubs recently, and are in a span-roofed house standing east and west.—LEWISDALE.

5031.—Marechal Niel Rose and Vines, &c.—I have a large Rose-tree in ainery where I have just finished cutting the Grapes, will someone kindly inform me the proper treatment for the above during the winter? Having pipes through the house, I can give heat if it is required, and good ventilation top and bottom when necessary. Should the latter be kept on all night as in the above? Would it affect either by planting Lettices in the house, having plenty of floor space (50 feet by 29 feet), which I want to make the most of?—NORICE.

5032.—A new greenhouse.—Will someone kindly oblige me with hints how best to furnish a new greenhouse, not intended to be fitted with many stages, and where flowers are desired that can be fairly easily managed without a very skilled gardener, and where it is intended only to keep sufficient heat (if it can be so regulated) as to keep fruit from? The conservatory is built on the angle of my house, and opens on to room; spare will be left in it to walk or sit. It measures 12 feet to south, but 20 feet to west, is 8 feet broad, and has Loughborough boiler, and pipes all along south side and to 14 feet of west, where they are stopped by floor out to lawn, and opposite to that in room, so that there is a cool corner to the west about 7 feet square. It contains a tank for soft water on south side.—G. E. C.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5033.—Pleiones (Tar).—I should be happy to assist you with names for your plants, but they must certainly come to me in much better condition than the blossoms sent, which might have been from their appearance some of last year's flowers.—M. B.

5034.—Black Hamburg Vines (Pine).—I have some good young Vines (Black Hamburg) two and three years old, grown in pots. I want to dispose of them. Where would I be most likely to do so to the best advantage? (Advertise in GARDENING, &c.)

5035.—Hymenophyllum (F. Baxter).—Yes; the plants of which you send specimens are of great beauty. They are popularly known as Filmy Ferns, and the two specimens sent are (1) Hymenophyllum autumnale, (2) H. hibernicum, and there is another one which is included with them, this is the Killarney Fern (Trichomanes radicans), and is more beautiful member of the family, and grows in a cool or cold room.—J. J.

ROSES.

FORCING MARECHAL NIEL ROSE.

ALTHOUGH this is such a disappointing Rose sometimes, inasmuch as no manner of coaxing will induce a plant to start into growth, there is no other Rose so valuable for growing under glass. I refer to the great length the branches will extend in one season, the number of flowers they produce, and the ready way in which the growth responds to fire-heat in the dead of winter after a short season of rest. The only profitable way to grow this Rose for forcing is to plant it out in a border where there is a fairly good root-run. It is not necessary to provide an expensive border for the roots, as the condition of my plants as I write testifies. If the natural soil is fairly deep and not too light, there is no danger of the plant not making good growth if the roots are given three or four doses of liquid-manure while the young growth is being made. My plants are put out in the natural soil of the garden and get a few doses of sewage during the summer, and they make splendid growth every year. With regard to pruning, I have not the least doubt but that the plan of cutting back as soon as the first lot of flowers is over is the proper way. The blooms produced by the young shoots are so much larger than those produced from spurs, that there is a considerable difference in their value when the produce has to be realised. My object is to get the flowers as large and as early in the year as I can. To do this, I find it necessary sometimes to thin out the young shoots early in the summer to give the others more room, as I find that the stronger the growth the larger the flowers. My plants are trained up near to the glass, and each shoot has a space of 9 inches allowed it. I find this is the only way to get thoroughly strong and well-ripened growth, and unless these shoots are well hardened by full exposure to light and air, the flowers come small and poor in colour. The next

POINT IN THE MANAGEMENT is to give the plants a season of rest. This is of the most importance when the plants have to be forced early. In my case I devote the house to the Roses, and leave the ventilators open night and day all the autumn and up to Christmas, except when it is actually freezing. Even then the joints of the shoots will continue growing in mild weather. I have found that it is of no use to attempt to try to stop them growing, so that I let them alone until about a week before forcing commences, when I cut off 2 feet or 3 feet from each shoot, as I find the best blooms are produced by the growth that is better ripened farther back. In previous years I did not commence forcing until the 1st of January, but this season I started the fire a week earlier as an experiment. This I shall not do again, as I find the flowers were not so fine, as well as giving me more anxiety when the young growth is being made. I could see if I had not managed the temperature very nicely the young shoots would have kept growing instead of forming flower-buds. Until the flower-buds

are formed the night temperature is 50 degs. to get it down to that point I had on several occasions to let the fire out. The reader will hear in mind that the temperature referred to was in the closing days of January, when the daylight at the best is often dull and of short duration; but at about the end of the first week in March it may be safely from 5 degs. to 7 degs. higher. Until the flower-buds were quite prominent the day temperature by fire-heat was not allowed to exceed 60 degs. In the middle of February I raised it to 70 degs. when the outside temperature admitted of the top ventilators being opened. Taken altogether, the previous season was not a good one for the forcing of fruits or flowers, as there was but little sun, and we had quite an average number of frosty nights and dull days, so that although I began forcing my Roses a week earlier last season, I did not have a proportionate number of blooms at the same date. About this time in former years I had out about sixty libons; last season the number did not amount to quite 100, an increase that did not pay for the additional fuel consumed and the anxiety caused by the uncertainty of the flower-buds forcing. I know that many amateur readers are averse to thinning out the bloom-buds of Roses, but this is what I do both under glass and in the open air, and my Marechal Niels are so vigorous that quite half of the young shoots produce three buds on a shoot; these I reduce to one as soon as I can see them, as one well-developed bloom pays me better than three small ones.

5028.—Climbing Roses in a greenhouse.—A single plant of Marechal Niel would fill up 20 feet of space in two years if it started well into growth, as this Rose sometimes does. For a lean-to house I should, however, prefer Climbing Perle des Jardins as one of the plants for the south aspect, General Jacqueminot for another, and Climbing Niphetos for that side. This selection gives you three distinct colours, and they are all Roses that can be kept within bounds by judicious pruning. For the west side W. A. Richardson will do for the cool corner, and L'Idéal and Reine Marie Henriette for filling up the remainder of the space. You must keep the growth at least 12 inches from the glass; 14 inches would be better. The only Passion-flower bearing crimson flowers that would be likely to suit you is one named principis; but this requires more warmth in the winter than would be good for the Roses. I think you must mean the Tacsonia; if so, the one named Van Volxemi is the kind you want; but if you do not give it plenty of roof-space it will overrun the Roses. The best plants for hanging-baskets are the Ivy-leaf Geraniums and the drooping forms of Tuberous-rooted Begonias.—J. C. C.

5013.—Roses in a cool greenhouse.—You may treat the two varieties you name exactly the same as Marechal Niel, as they are of similar character. W. A. Richardson is more perpetual blooming than C. Devonlands or Marechal Niel, but all three of them should be treated upon the long rod-system. There have been a good many queries lately about Roses in

cool-houses, and as the time is fast approaching when a considerable amount of work will need attention among them, I propose giving a few notes very shortly.—P. U.

I have never been able to do anything with Climbing Devonlands under glass. It makes too much growth, and does not flower freely. Possibly in a large, light house, rather pinched at the roots, it might do better. William A. Richardson and Climbing Niphetos would do very well with Marechal Niel.—E. H.

5031.—Marechal Niel Rose, Vines, &c.—As your Grapes are late you will need to give them a slight rest. The Rose will also benefit from this for a time longer. You cannot bring one on more forward than the other. I should allow a little air every day, except during severe frost, until the early part of January; then let them break steadily and naturally, aiding them with gentle fire-heat as they advance. You could hardly have a better plan for your late Lettuces, and no harm can come of placing them in this structure. There are several other subjects, such as Dentzia gracilis, pot Roses, and other hardy flowers, which would benefit very much from a short period here before being introduced to heat.—P. U.

The Rose will do well with the treatment you give the Vines if you only use fire-heat to keep out frost. You are, however, quite right in supposing that the growth of this Rose requires plenty of air to ripen, and the more you ventilate the house the better your Rose will behave, and the Vines will be benefited rather than not. You may plant Lettuces on the floor of the house without doing any harm to the present occupants, and if you wish you may use fire-heat sufficient to maintain a temperature of 40 degs.—J. C. C.

5000.—Seedling Brier-stocks.—I take it that there is a slight misprint in your query—the word "bedded" should read luddled. Presuming such to be the case, I may say that they should not be cut back at all until the spring following their being luddled. Do not plant them deeper than the collar of the stock. It is a good plan to plant them rather shallow, and then draw some soil around them. This protects them through the winter, and also makes it much easier to bud upon the roots in summer, as the soil is quickly removed, and leaves the bark in a softer and better state for working.—P. U.

Straggling shoots may be shortened back to make the plants shapely, but there should be no general cutting back. Whatever pruning is required should be done now.—E. H.

5030.—Pruning and repotting Roses.—Tea Roses in a cold greenhouse. The Roses should be pruned at once, and the repotting may be done any time before the end of January, but do not repot in your case in frosty weather. As soon as potted bring the plants to the south side of the house, and stand them on the floor, and if the frost is likely to be severe enough to freeze through the ball of soil, you had better cover them up with mats, not that the frost will injure the roots, but it will bring the ball of soil away from the side of the pot, which is not desirable. From the beginning to the middle of June is a good time to stand them out of doors, and the middle of September is a good time to take them under glass

again. You must, however, be guided by the weather prevailing at the time when the last two operations are advised to be done. The more genial it is the longer they may remain in the open, providing they stand in a position pretty well sheltered from the wind. You had better have a bed of coal-ashes to plunge the pots in while they are in the open air.—I. C. C.

GARDEN WORK.*

Conservatory.

Large Chrysanthemums may be shifted into larger pots if large plants are required, but a good deal may be done with stimulants. Pelargoniums may be shifted on as soon as the pots they now occupy are filled with roots. Under no circumstances should they be permitted to get very much pot-bound before repotting. If insects appear on the foliage, which is not unlikely, either fumigate with Tobacco or dip in a solution of some insecticide, of which there are now numbers in the market. Half a tumbler of Sunlight Soap and one ounce of Potash-water will make a good wash for three gallons of water. Half the soap in a gallon of water, and add the other two gallons afterwards. Use at 100 degs. of temperature. Take cuttings of Chrysanthemums. After this date it is best to take good cuttings as soon as they can be obtained. The best cuttings are the strong sucker-like shoots which spring from the bottom of the plants. Those who are thinking of buying any of the new Chrysanthemums should send in their orders to get the plants in the plants. Big things will keep hold of the public taste, and the limit of size has not yet been reached. Some day, I suppose, there will be a reaction, and the Pompons will come in again. As plants go out of bloom and become shabby take them out and fill in with other plants coming on. Personally, I feel rather glad some of the Chrysanthemums are over, for when present in such numbers as are grown now they take possession of the place, and are growing too big. When they are thinned down we begin to realise how beautiful groups of Bulbs, Cyclamens, Primulas, and Geraniacs can be made with a setting of Ferns and other foliage plants. Small seedling plants of the green-leaved Brassicas are suitable for mixing with dwarf flowering stuff. *Cyprus aristata* in small pots may be used on this principle. *Convolvulus* and *Aralias* may all be raised from seeds, and have some decorative value when about a year old. A rearrangement of the subjects always gives pleasure, as if different subjects as they come into bloom. A good deal will be done in the future with the new dwarf *Cannas*; wherever there is warmth there will be plants in bloom. The only fault to be found with them is, the flowers do not last long; though, perhaps, this will not be noticed much, as the flowers open every morning. *Tuberous Begonias* will now be dried off, and their place will be taken by the Illinois-rooted species and varieties which are now coming in, one of the most useful being *Isidias* and its varieties. A mass of this will now be a special feature in many conservatories. Poinsettias are now at their best, and with a careful regulation of the temperature and the atmosphere humidity the leaves will last a long time. There is now a prospect of cheaper fuel, and, fortunately, up to the present there has been no very severe frost.

Stove.

Dendrobis and other winter-flowering *Orchids* are coming in, and, besides these, there are many other plants that will flourish freely in a night temperature of 40 degs. or a day, or two more. We shall soon pass the shortest day, and the increasing daylight will stimulate the opening buds, both of leaves and flowers. Many of the plants will be for the most part at rest now. Some exceptions there are, among which may be named *Franzosa cypripis*, a beautiful winter-flowering stem shrub that flowers with the greatest freedom when the wood has been well ripened by exposure in summer. *Gardenias* will now be coming in, and among them *Banjamin gracillimum*, *Impatiens Nordalica*, and the scarlet Passion-flower (*Passiflora principis*) will help to beautify the upper part of the house. For *Tulips* as soon as they come to hand, at intervals of a month or so. The earliest potted bulbs will now be on the move, and may receive more heat. If plunged in a brick bottom-heat the flower-sticks will come on faster. Atmospheric humidity should correspond with the amount of fire-heat used. A dry, scorching atmosphere will soon fill the house with insects.

Bedding Plants.

For the present these cannot be kept too cool, provided the least is kept out, and being kept cool means, of course, they will not require much water. As soon as the new year comes in those plants from which cuttings are required may be taken to a warm pit or house, as young cuttings strike so much better than the shoots produced in a low temperature. Dead leaves should be frequently removed from *Verbena*. *Veronica* must be thinned with a sharp knife, as soon as they come to hand, if available in frosty weather, in which they are rather subject. The usual run of plants employed in repotting, such as *Cobuses*, *Veronica*, and *Alternanthera*, cannot be kept safely in a much lower temperature than *Calceolae*. The back shelf of a stove or forcing-house will suit these very well.

Forcing-house.

There will be a good deal to do in this department now, in addition to the usual flowering plants which are in demand for Christmas and New Year parties, and which include Dutch bulbs, *Azaleas*, *Rhododendrons*, *Deutzias*, *Spiraeas*, *Araucarias*, *Tea Roses*, *Lily of the Valley*, &c. French Beans may be brought forward, Vines in pots and Cucumbers are sometimes grown in the same house. Careful management is required where the occupants of the forcing-house are many and various. In small places where the houses are few in number I have seen all the above, with *Tomatoes* in addition, all being well treated in the same house. There is often more skill

brought to bear on the moderate-sized forcing establishment than in large places, where separate houses are devoted to the different subjects grown.

Early Strawberries.

Where many Strawberries are forced, the first batch of plants will soon be started. Strawberries are rather accommodating in the matter of temperature, but they do best when started in a night temperature of about 50 degs., gradually advancing as the plants progress, 65 degs. during the maximum when the fruits are set and swelling. A low pit filled with leaves is a good starting-place for the first batch, the plants to be moved to a light, airy structure, with a night temperature of 55 degs. to 60 degs. when in bloom, with air more or less always when the weather is mild, the cannel's hair brush used daily when the plants are in blossom.

Cold Frames.

Violets and all other hardy subjects must have as much fresh air as can be safely given. Keep all plants free from dead leaves. A freely stirred surface-soil tends to keep the atmosphere pure, and the plants are always healthy under such conditions.

Window Gardening.

There are plenty of plants in blossom now suitable for filling starry windows. Among these are *Cyclamens*, *Roman Hyacinths*, *Primulas*, *Hebeas*, and *Joss* or *Sacred Solids*. The latter will grow just as well in soil as in water and pebbles. Flowering plants and Ferns must not be allowed to get dusty, and a little weak stimulant may be placed in the water occasionally. Half an ounce in a gallon of water will be sufficient to make some impression upon both growth and blossoms.

Outdoor Garden.

At this season there are always improvements to be carried out, and as long as it keeps open alterations of all kinds may be done. The removal of trees and shrubs to create special features is always interesting work. Some trees are planted which are not adapted for that particular position, and it is more for just to remove them so perfectly arranged as to require no changes—and it is far better to move some of the things altogether than try to make room for all by cutting and lopping. This is, in fact, one of the greatest evils attending the planting of small gardens. Many things are planted at first that were required, and the further error is made by cutting back instead of thinning out. A mutilated tree or shrub is never satisfactory, because the true character is not seen. Very interesting work is the formation of such special features as *Roseries*, or borders for *Chrysanthemums*, or groups of shrubs and lilies. All of these things require special care in the preparation of the soil, and the winter, when there is more leisure than usual, and when cheap labour can be had, is the best time to carry out such work. Creepers on walls may be gone over, and what pruning is required may be done, and the necessary tying or nailing should be seen to. *Hydrangeas*, plants, *Bulbs*, &c., will in many instances require new labels. Names of plants are very apt to be moved or lost during the autumn clearing up. It is, perhaps, not advisable to have the labels too conspicuous, but still they should be seen without much difficulty. If the names of *Roses* are lost, it is not every person who can name *Roses* at sight; and, of course, such things as *Philoxera*, *Diphtheria*, and other hardy forest flowers are in a hopeless condition when the names are lost.

Fruit Garden.

The early Peach-house and the early luxury should be placed in condition for starting. This means that the house requires a thorough draining in every part with soap and water, and the walls should be whitewashed. When this is done, and the ladies have received their annual top-dressing of free loam and Thomas's, or some other manure, the houses may be closed preparatory to forcing if early Grapes or Peaches are required. I am assuming, of course, that the trees require their annual dressing before the house is drained. This annual dressing in many gardens resolves itself into a wash with Gishurst compound or soft-soap and water. Where there are no insects strong mixtures are not necessary; if there has been any miller on the trees during the past year, extra precautions should be taken to destroy the species which are present in the house. A strong solution of Gishurst compound (6 oz. to the gallon) will destroy any miller species which may be hidden away in the bark without injuring the Vines in any way. Hardly fruit of all kinds will benefit from a dressing of some simple insecticide. Sant, lime, and soft-soap made into a wash that will pass through the garden-engine will do much good in cleansing trees from parasites of all kinds, and it brightens and cleans the bark. This dressing may be given as soon as the pruning is completed, and may be repeated any time during the winter. If anything stronger is required increase the quantity of soap to 4 oz. per gallon. Apple-trees affected with *Arctian* blight must be thoroughly scrubbed with Gishurst compound (6 oz. to the gallon), brushing the liquid into every part of the tree. These trees which are badly affected had better be girdled up, and after girdling and in the roots and remaining some of the exhausted soil and fill up with fresh plant a young tree. In most gardens the old should give place to the new.

Vegetable Garden.

Trough and manure laid for plantations of Asparagus. The soil cannot be too deeply stirred, and the manure dressing must be liberal. Continue to make up Mushroom-beds at intervals as required. A Mushroom-house cannot well be too large, as so much work can be done in them besides growing Mushrooms, and the larger they are, if properly reeled, the roofs covered with thatch, the less fire-heat will be required. They may suit parsnips, and the larger the house the more beds it will contain, and fermenting masses of manure will keep up the requisite temperature. Many gardeners have broken away from the old-fashioned plan of sowing the manure in small quantities and drying it in a shed. If the manure is brought fresh, or nearly so, into the shed, and after the longest litter has been shaken out, one-fourth of good loam is mixed with the short manure and thoroughly mixed. As well as use in it at once, plant the rows here and there as soon as the proper temperature is reached, and the use of good deal of time and labour. Liquid manure may be given freely to beds which have been sown some time. Sow early Peas and Beans on warm beds. These

the seeds with rod lead before sowing. It will not take long, and will keep them safe from mice. Put long litter over Jerusalem Artichokes. Globe Artichokes will require protection from severe frost. Potato heaps may require require more covering. Never a severe frost comes in, but roots are frozen which ought not to have been left in an insecure state. Make provision for securing a stock of Parsley in severe weather. It is a good plan to have a bed on a south border which may be covered with a frame, and the frame made secure with mat or litter. Salad material must be looked after carefully now, especially Lettuces, Sorrel, Mint, Cherril, and Tarragon may be potted in winter. E. Hobday.

Work in the Town Garden.

Christmas will soon be here again, and as most of us will to see a few flowers about, then a little extra heat may be employed to push things on into bloom by that time. *Roman Hyacinths* that were potted early—in September or the beginning of October—will have formed plenty of roots by this time, and be beginning to move a little, and if now cleaned and brought into a genial temperature of 50 degs. during the day, the soil kept at 60 degs., and what can be secured, and prefer the single-flowered pure-white form? *Narcissi* of several kinds, but notably the Paper-white and "Stella" (*incomparabilis*), will bloom quite as early and readily as the last, with the same treatment and very little forcing, and the pretty little *Soilla silvica* also responds quickly to a little warmth at this season if planted early. These may either be grown separately in pans or pots, planting the bulbs rather closely, or else be planted among the *Roman Hyacinths*, with which they produce a charming effect. An important point in forcing both *Hyacinths* and *Narcissi* at this early season is to prevent the spikes and foliage from becoming unduly drawn, and this is easily prevented by keeping the pots near the glass, and by avoiding a very high temperature. When such things are grown simply for supplying cut flowers a great saving of both space and labour is effected by plunging the pots in a shallow tub in which there is 3 inches or more of water, in which they do quite as well as in pots. The market-growers, indeed, almost invariably grow them in this way, even for pot work, lifting and potted the plants when in bloom, as by this means far more even pots are secured than by the other method. Lilies of the Valley are always admired, but these require more heat than the preceding, and are best managed by plunging the pots in crowns in Cresson-nut-tree or ashes in a warm-house or pot, and covering them about 6 inches deep with the same, which must be kept constantly moist. As soon as the tips of the leaves appear through the fibre take out the pots, lean them, and introduce them gradually to the light in a temperature of 40 degs. to 50 degs., when the foliage will quickly gain colour and the flower expand. In very sunny places *Chrysanthemums*, like the *Zonal Pelargoniums*, prefer to expand in the depth of winter; but strong, early-sown plants bloom beautifully now in a light house kept at a range of 45 degs. to 55 degs., where the air is tolerably pure, as in country places, or even the outer suburbs of London. The *Persian Cyclamens*, however, do not on a shelf near the glass in a tolerably warm structure. The early-flowering varieties of *Epacris* are now expanding beautifully in a warm greenhouse. These are far better town plants in every way than the *Ericas*, and the flowers very enduring. I. C. C.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from December 9th to December 16th.

Put in cuttings of *Chrysanthemums* of various kinds, chiefly of those which require time to bring up the flowers. The cuttings are in a cool-frame placed in a cool-house, where they will be kept in a position which is a better position than a cold-frame or pit outside, where heavy coverings would be necessary to keep out frost. From the time the cuttings are inserted till the plants are moved outside in May, they cannot have too much light or too little fire-heat. Dipped *Pea-argemiums* in a solution of Sunlight soap. A greenfly in two has been seen on the plants lately, and dipping is cheaper and usually more effective than fumigating. Made up hot-beds with leaves and manure. Asparagus, Potatoes, Lettuces, &c. A good deal of produce can be raised under glass with the cheap frames, if there happens to be any, as there generally is a good supply of leaves in a country place, which can be had for the labour of raking up and carting. A bed made up now for Asparagus, when the Asparagus is removed, will come in very useful for Lettuces, Radishes, Potatoes, and Turn Carrots. Still busy among the trained fruit-trees, pruning, training, and washing. Always make it a rule when the training and training is finished to give the trees a thorough wash with an insecticide. It is usually done in this way. When a wall of *Plum* or *Pears* or *Cherries* is finished sufficient wash is made up in a large tub to do the trees in that particular wall, and when that time is done the borders are manured, if necessary, and dug or loaked over to put in the air. All ground, whether planted with fruit-trees or not, should have the surface opened up now to let in the air to make the surface of the soil well pulverised. Roots do not, I think, enjoy being always in a dark, close soil; therefore, as far as possible, without breaking or digging among the roots at close quarters, we endeavour to let in the air and what little sunshine may be had between this and next March. I have just planted a lot of young Apple-trees on the Paradise stock. The varieties include *Earlwin*, *Pott's Seedling*, *Blenheim Orange*, *Cox's Orange*, *Pippin*, *Golden Pippin*, *Albion*, *Green Pippin*, *Summer Red*, *Lawson's Green*, *Winter Pearmain*, and a few others, including *Dumblin's Seedling*. The trees are all established, with blossom-buds, and, bearing in mind a previous experience with the same kind of trees, a light crop could be had next year if it was desirable. For small garden planting, or large either for that matter, I have the greatest faith in these dwarf, sturdy, thickly-budded Apples. Top-dressed Cucumbers with turfy loam mixed with a little of manure. If a good light, roomy house for Cucumbers, and the plants do better when they have room to strike out, and where the house is large enough to expose the air to be always in motion. My experience has been that Cucumbers are not nearly so difficult to keep in good condition in large houses as they are

* In cold or northern districts the operations referred to under "Garden Work" may be done ten days to a fortnight later than those indicated with equal success.

in small, stuffy places. Started more Seakale and Rhubarb in Mushroom-house, and moved a few more shrubs, Roses, Lily of the Valley, &c., into forcing-house to take the place of the plants moving out to conservatory. Planted more French Beans in pots for forcing, *St. Ulis Ultra* being the variety. I like this best for very early work, as it turns in so quickly.

GLADIOLI.

THESE beautiful flowers have of late years become very popular, and right well do they repay all the care that can be bestowed on them, for whether you cultivate the brilliant *G. Brenehleyensis* or the more varicoloured *G. gandavensis*, or the mixed hybrids now so much grown as market flowers, including, of course, the beautiful addition of *Mms. Lemoine*, with their wonderfully varied colour, the work is pretty much the same. I have just lifted the roots of all these kinds. Thrusting a steel fork well down beneath them, I lift them from the soil, with the tops on them, and lay them carefully in boxes, so that all the tiny little tubers that form around the base of the old bulb may be saved for planting out again early next season. They are set in any cold greenhouse or shed where they are safe from frost until December, when the old tops are cut off, and the bulbs sorted into different sizes, all that are of flowering size being stored in bags or boxes, secure from frost, and the small bulbs are put away for growing on. The work of preparing the site for next year's flowering beds should now be taken in hand, and if possible fresh soil should be selected for them every year, as there is a great difference in the size of the blooms and bulbs as well when they are planted on soil solely devoted to them and planted at a good distance apart. I am now manuring and deeply digging the soil intended for my next year's *Gladiolus* beds; it will then lay up roughly exposed to the elements until next March, when, selecting a dry day, the surface is levelled down, and rows marked out 2 feet apart, the bulbs being then put in with a trowel 1½ feet apart; they are let down about 4 inches below the surface. All the attention they need in summer is keeping the surface-soil frequently stirred to keep down weeds, and if the season proves very dry artificial watering will be helpful. But we seldom resort to that on deeply cultivated soil. The bloom-spikes will begin to push up soon after midsummer, and during August and September they will be in full beauty. In cutting the spikes on well-grown plants, flower-spikes will be seen pushing out from the main stem, and these side-shoots keep up a succession until very late in the season; in fact, we had *Gladiolus* blooms until the frost stopped them, and few flowers are more appreciated in private houses, or sell more readily in market; the bulbs increased rapidly, not only in size but in number. The beautiful *Gladiolus* called "The Bride," much grown in pots, is also excellent for outdoor work, but flowers earlier in the season and should be planted earlier. I plant my stock of The Bride at the same time that I lift the others, and I find that some of those left in the soil all the summer are pushing up strongly, although the weather is by no means exciting to growth. They are very useful for cutting, being pure-white.

JAMES GUNN, Gosport.

5021.—Artificial manure.—It would be a difficult matter to decide which is absolutely the best artificial manure, so much depending on the nature of the soil and the special requirements of the particular plant to be benefited. Ichthonic Guano or Chy's Fertiliser are excellent manures. If you have leaves at command by all means make use of them; their decay would be hastened by weeds or other green vegetable matter being mixed with them in a heap together. Kitchen refuse is a good manure. Not far from me is a small garden that has been transformed from poverty to fertility by the employment of material that most people let the dustman take away. Where land is of a close, heavy nature, anything of an organic nature, such as paper, rags, old bags, pieces of carpet, &c., would improve its texture; but where the soil is full of inert vegetable matter, as it is in some old gardens, these things would do more harm than good. But Cabbage, Broccoli, and Turnip-leaves would benefit any kind of soil. Some years ago, and long ago, soil that I was planting with Potatoes, I dug in

some green Broccoli-leaves by way of experiment. Where these were dug in the haulm was higher and greener than that in the rest of the plot where nothing was used, and when the tubers were lifted there was a great difference in the size of those that grew where the Broccoli-leaves had been put than where nothing was dug in at planting. Leaves of the plants of the Brassica tribe give a bad smell when undergoing decay, but this can be remedied if they are covered with earth.—L. C. K.

HOUSE & WINDOW GARDENING.

HARDY CLEMATISES FOR WINDOW DECORATION, ETC.

Few plants are capable of being used in so many ways as these Clematises. They may be well employed to adorn the walls and windows of the dwelling-house, for which they are especially well adapted, as their habit of growth is so free and graceful, and the blossoms are produced in great profusion, and contrast well with any other flower near them. They may also be employed with great advantage to cover any

Clematis "Lady Caroline Neville."

other bare wall-space near the dwelling house, and for pillars out-of-doors or in cool conservatories, for overrunning tree-stumps and shrubs, or for bedding purposes, they are admirably adapted, and when well grown they furnish a mass of gay flowers for months during summer. In order to induce Clematises to produce a long succession of bloom, liberal culture is necessary—indeed, indispensable; for unless a vigorous growth in the plants is secured they will flower but sparingly. A deep, well-drained soil, consisting of good friable loam, rotten manure, and leaf-mould, is the best compost in which to plant them, and during very dry weather liberal supplies of weak manure-water may be given with advantage. Although the choicer kinds are usually increased by grafting, if cuttings of the young shoots be taken off in spring and inserted in a gentle bottom-heat under a hand-glass, they will form good flowering plants under favourable circumstances the following season. Two of the best Clematises for home-decoration are *C. Jackmani* and *C. Lady Caroline Neville*. The former kind is here figured. The names of other good and hardy kinds may be found in almost any nurseryman's catalogue.

CHRYSANTHEMUMS.

GROUPS AT CHRYSANTHEMUM SHOWS.

A GROUP of Chrysanthemums is very showy, and with the varied colours and forms lends itself to more tasty arrangement than any other flower; but, however well they may be arranged, there is a certain amount of heaviness. I have seen groups at all of the southern shows this season, and grand as the premier group at Brighton was, both in arrangement and quality of blooms, it would have been considerably improved if one-third of the plants had been missing, and their place taken by a few Ferns. The adaptability of these two to form a pleasing combination was well exemplified at Eastbourne, where a class was framed for them. An imitating bed of Ferns, having a few good blooms showing well above them, and the outside of the group set off with various *Pteris* and *Adiantum*, was a feature of the show. There is far too much attention given to good flowers where groups are concerned. Plants are grown with two, three, or at the most four blooms, and when these are placed so thickly together, as is generally the case, the size and weight produce a ponderous and heavy effect. Smaller, more naturally-grown blooms, having an occasional large flower slightly raised, would have a much more pleasing appearance, besides acting as a foil to one another. These large blooms are too frequently obtained at the expense of leggy and gaunt plants, and this defect would be covered by the use of a dwarfier and bushy habit, which is easily secured with a full show of medium blooms, and if, combined with this, we use a few Ferns, the effect is exceedingly good. On suggesting this to a well-known grower, he asked which the judges would take most notice of; were they to judge the Chrysanthemum only, or the whole combination? The classes at Eastbourne read, "to consist of Chrysanthemums and Ferns," and, again, "Chrysanthemums and other plants, Chrysanthemums to pre-eminence." In awarding prizes the combined effect should certainly be the test. In both of the above classes I noticed that a few good flowers had a much better effect among other subjects than when among their sister flowers only, where they are comparatively lost.

P. U.

5014.—Japanese Chrysanthemums.

—THE following thirty-six varieties will be found suitable, the first half being Japanese and the remainder belonging to the incurved section: Vivian's Mirel (deep-mauve), Charles Davis (brunze-yellow), Mlle. Thérèse Rey (creamy-white), Avalanche (pure-white), Edwin Molyneux (crimson, reverse gold), Stanstead White (pure-white, large), Sunflower (rich-yellow), W. H. Lincoln (orange-yellow), Mrs. F. A. Spaulding (brunze-yellow), Mrs. Fulmer Jackson (brunze, tinted and striped with yellow), Etiole de Lyon (deep-blue, rose, shaded silver), Florence Davis (pure-white, green centre as it expands), Excelsior (crimson), W. Seward (blackish-crimson), Mlle. Marie Hoste (white striped, and bordered pale amaranth), Mrs. G. C. Schwabe (delicate rose, shaded salmon), Alberic Linden (amaranth), and W. Tucker (delicate rose, full and handsome). Incurved: Lord Abinger (primrose-yellow), Queen of England (rosy-blush), Golden Empress (yellow), Golden Rose of England (straw-yellow), Empress of India (pure-white), Charles Gibson (deep bronze-red), Hero of Stoke Newington (rose-pink), Jeanne d'Arc (bluish-white, tipped purple), Lady Dorothy (pale cinnamon-luff, suffused with rose), Lord Wolseley (brunze-red), Prince Alfred (rose carmine, shaded purple), Miss M. A. Huggan (soft-yellow), Princess of Wales (bluish-rose, striped deeper), Mrs. Culnham (bright-rose shaded yellow), Mrs. Heal (creamy-white), Princess Teck (bluish-white), Miss Violet Tomlin (bright violet-purple), and Jardin des Plantes (rich orange-yellow).—E. MOLYNEUX.

—THE following are all well up to date, Japanese: Duke of York, Excelsior, G. C. Schwabe, Princess Mary, Viscountess Hambleton, William Seward, Col. W. B. Smith, Golden Wedding, George Savage, Lord Brooke, Mrs. T. Denne, Mrs. E. D. Adams, President W. R. Smith, Primrose League, Mrs. C. H. Payne, Mme. Hoste, Gen. W. Childs, Chas. Davis, Mrs. Dr. Ward, Infant des Deux Mondes. Incurved: Baroness, Brockleigh Gem, Robert Pettiford, Ami Hoste, Mrs. R. King, C. B. Whit-

nall, Lucy Kenhall, Mrs. J. Mitchell, Mrs. S. Coleman, Mme. Darrier, Violet Tomlin, Miss M. A. Haggas, Lord Walseley, Princess of Wales, Mrs. N. Davis, Lord Alcester, White Empress of India, Jeanne d'Arc.—E. H.

5008.—Chrysanthemum cuttings.—You may strike the cuttings in a cold green-house, as coddling of all kind must be avoided. When they are struck, however, in an ordinary cold frame there is delay from frost, and the wiser plan is to have a hand-light or small propagating frame to an ordinary greenhouse, with a temperature of about 45 degs. No air must be admitted until it is seen that growth is commencing; but after that period give air gradually, and cautiously take care that only sufficient water is given to thoroughly moisten the soil, otherwise they will damp off wholesale. The culture of Chrysanthemums for exhibition has now fairly commenced. Grow them freely throughout is a good axiom for the novice. Once allowed to receive a serious check and stunted, unsatisfactory growth will result. Always attend closely to such simple but too often neglected operations as potting and watering. The plants are better if kept in the greenhouse, and plenty of air maintained above them to ward off mildew and other ailments. Where the cultivator is not the happy possessor of a greenhouse or cold-house of some kind the frame must be used. Many have to rely upon an ordinary frame for growing their treasures. Select the best cuttings, not those from the stem, and about 3 inches in length, sturdy, and cut just below a joint. The plants may also be propagated by suckers, and the best way is to put each cutting in a small 60 pot, not inserting, as is the usual custom, several round the sides. See that the pots are thoroughly clean, and use good light loamy soil.—C. T.

—Chrysanthemum cuttings may be struck in a cold greenhouse, but they must not be exposed to frost. I am now striking mine in a frame set in a cold span-roof house, but fire-heat enough will be used to keep out frost, or else the frame will be covered with mats. The less fire-heat the cuttings have the better, but they must not be frozen. Any good light soil will do. I generally use loam and leaf-mould in equal parts, mixed with a little sharp silver sand.—E. H.

5004.—Reflexed Chrysanthemums.—The following are the best dozen belonging to this section: Cloth of Gold (light yellow, full flower), Dr. Sharpe (purple-magenta), Golden Christine (light-fawn colour), Pink Christine (pink), Peach Christine (pale-peach colour), Mrs. Forsythe (creamy-white), Putney George (crimson), King of Crimson (rich sanguineous-crimson), Cullingfordi (brilliant dark-crimson, reverse gold), Felicity (pure-white, lemon centre), Chevalier Domago (orange-yellow), R. Smith (reddish-magenta, reverse gold, spart from Dr. Sharp).—E. MULYBEX.

—A dozen of the best in this class are: Cullingfordi (crimson-scarlet), Chev. Domago (deep golden-yellow), King of Crimson (dusky-crimson), Putney George (bright-crimson, with gold tips), Elsie (canary-yellow), Hetty Dou (pale-white), Progne (amaranth, fragrant), Phidias (rosy-blush), R. Smith (a kind of orange or reddish-crimson), White Christine and Boule de Neige (both white), and A. J. Banks (primrose). Dr. Sharpe (magenta-crimson) is very free and excellent in every way, but its colour is against it; and Julie Lagravere, a beautiful rich velvety crimson flower, is, unless afforded special treatment, usually too late for the November shows.—B. C. R.

—This is not a very large but interesting class. The best varieties are Amy Furze (best described as a delicate rose-lilac shade), Boule de Neige (white, and valuable for its lateness), Chevalier Domago (golden-yellow), Cullingfordi (rich crimson-scarlet, the most useful of all in its line of colour, and a really superb flower), Dr. Sharpe (a variety that has been many years in cultivation, the flowers of a purplish-crimson shade), Elsie (a lovely variety, the flowers beautifully reflexed, and very soft-yellow in colour, one of the best Chrysanthemums for decorations in cultivation), Golden, Peach, and White Christmas are all worthy of a good place, the colour of the flowers indicated by the name. Phidias (rose), Progne (amaranth, scented like Violets), and Putney George (crimson, the reverse of the florets golden-yellow, and tipped

with the same shade). All the foregoing are of value for exhibition. Julie Lagravere is a reflexed Chrysanthemum, but not a show variety. It is a splendid kind for November flowering in the open, and is the dark-crimson variety one sees so much of in the parks in the autumn.—C. T.

TREES AND SHRUBS.

FLOWERING TREES AND SHRUBS.

PHILADELPHUS (Mock Orange).

A VALUABLE genus of shrubs commonly represented by the lamellar Mock Orange, or Syringa (Philadelphus coronarius), found in almost every shrubbery. There are a great many kinds, but

Philadelphus microphyllus (natural size).

such a strong similarity exists amongst them that it is necessary to make a limited selection of the very best. To many the common sort is objectionable on account of the powerful odour of its blossoms, but it is such a vigorous grower and profuse flowerer that one cannot well do without it. It is well met to plant it too near the house or a walk. Very much finer in every respect are the North American species, which are best represented by P. grandiflorus, P. inodorus, P. speciosus, and P. Gordonianus. These are all of large growth, rising from 6 feet to 10 feet in height, forming a rounded mass almost as broad as high. They have all large white flowers in clusters, with little or no scent, produced from midsummer till the end of July. The largest flowered kind of the Mock Orange is P. grandiflorus, the blossoms of which are fully 2 inches across and of snowy whiteness. Scarcely less beautiful is the variety of it called laxus, on account of its habit of growth and flower-clusters being less dense. There is not a finer white flowering shrub in our gardens than this beautiful Mock Orange, and if there is only room in a garden for one kind, this is certainly the one to plant. The others, though they resemble one another in growth and flowers, are desirable because they flower in succession, and so extend the blooming period. P. inodorus, Gordonianus, and hirsutus are all fine species, and if space will admit, to these may be added the slender-growing P. Satsumi from Japan, P. Lewisii from North America, and P. verrucosus, also American. Most of these are procurable in nurseries, but are not invariably known under the names cited; indeed, so confused are the names of the Mock Orange in nurseries, that, with the exception of such as P. coronarius and grandiflorus, one can never be sure of getting the species true to name. There are numerous named varieties of P. coronarius, including one with semi-double flowers called primulaeflorus, but it is not desirable, as the doubling of the flowers is not

complete. A really ornamental variety is the golden-leaved form (folia aureis), whose foliage is of a bright golden-yellow tint and particularly bright in early summer. It is a most effective shrub to plant in company with contrasting foliage like that of the purple Hazel or purple Cherry Plum. It should be planted if possible in partial shade, otherwise its foliage is damaged by the hot sun during summer. An extremely pretty little shrub is P. microphyllus (see illustration), which is the pigmy of the genus. It has smaller foliage than the Myrtle, has slender branches, which in summer are whitened with a profusion of small flowers. It has been rather recently introduced from New Mexico, and though hardly enough for the south, is perhaps too tender for northern or cold districts. The variegated leaved form of P. coronarius is also an attractive shrub, the variegation being creamy-white and deep-green.

MOVING HOLLIES.

DURING the past week I saw a splendid hedge of Holly being transplanted; and as the present time is by no means suitable for transplanting this evergreen, and many of the failures respecting Hollies can be attributed to unseasonable moving, I venture to give a few notes upon the subject. December, January, and February are the three worst months that can be chosen. Hollies are never so much at rest as many other evergreens, about April being the least active period of growth. It is then that they shed the leaf, and experience proves that April and May are the two best months for transplantation. Early in September is also a good time, but I prefer early spring planting. If showery weather does not prevail, it will be necessary to give considerable attention to watering, both at the root and overhead. During the dry spring of 1893 and havoc was caused among fresh-planted Hollies, as owing to the scarcity of water it was impossible to aid them in the required direction. I could point to more than one hedge where some 15 per cent. to 30 per cent. only survived. In this respect autumn planting is a little safer, but unless we do this sufficiently early to secure new roots the same season, good results are not often secured. Whichever period be chosen for transplantation, I would strongly advise a good watering, followed by a mulching of manure to ensure moisture being retained. So many evergreens are moved during winter and early spring that I thought a caution note to move the Holly too early might perhaps save many readers from disappointment.

P. U.

The Chimonanthus.—A delightful winter shrub is *C. fragrans*, which blooms in midwinter. It should be planted against a wall, and will grow in comparatively small gardens. One of the finest specimens of it is on an old wall at Kym House, Isleworth. The leafless shoots are identified with comparatively large flowers of yellow, with crimson sepals, and they are richly fragrant. It should have as sheltered a position as possible, or facing south, the flowers being then less likely to suffer from adverse weather. When twigs are cut and placed in a small vase in the house they spread abroad in sweet, but not fragrant, smell.—C. T.

4909.—Quick-growing Ivies.—The broad-leaved Irish and Hibberd's Emerald Gem are fast-growing Ivies. The last-named will make the neatest cover, the leaves being smaller. It may be planted now.—E. H.

5007.—Bees and Carnations.—I should not think the flowers could be greatly hurt by the Bees, if the Ivies are not too numerous. Show Carnations should not be cultivated in their vicinity, unless they are protected in some way. Bees will not be affected—at least, the little damage Bees inflict would do no harm to the effect of the flowers in the garden.—C. T.

—I keep Bees, and also grow Carnations and Roses, but have never known either to be injuriously affected by them. The honey-Bee visits the wild Brier Rose, but I have never noticed it at work on either my garden Roses or Carnations; it may, however, visit the latter, as I have seen it at work on the Pinks, but certainly without any harmful effect, so far as my observation goes. For every honey-Bee which visits a flower there must be twenty other insects which also visit it, all equally injurious. If fruit is desired, either in the shape of seeds or in the shape of Apples, Pears, &c., the honey-Bee is the gardener's greatest assistant towards that end.—E. T.

INDOOR PLANTS.

FORCING WHITE FLOWERS.

Those who require a large supply of white flowers during the early spring should lose no time in getting the plants or roots prepared by potting or repotting, so that they may be gradually brought forward in a higher temperature. The following are all reliable:—

AZALEA INDICA, of which beautiful plants, full of flower-buds just ready to burst into bloom, can be bought at a very reasonable cost, are sure to give satisfaction, as they need but very gentle heat to make their blooms expand very early in spring, and as a decorative plant, or for cut flowers, they are almost unrivalled. *Dentsche Perle*, *indica alba*, and *Fiebler's White* are amongst the best.

CALLA ETHIOPICA is one of the very easily grown plants that flower at all sorts of times in the year, but never better than in early spring. They should get a rest out-of-doors during summer, and be repotted about midsummer, when they will push up very sturdy growths, and must be placed under glass in September and well supplied with liquid-manure, and kept near the glass in an intermediate-house, with a temperature from 50 degs. to 60 degs. If fly appears fumigate immediately. They will commence to flower about Christmas, and continue to push up their pure-white spathe freely as the sun heat increases, and as cut flowers for church decoration they are very valuable.

CHRISTMAS ROSES are lifted and forced in heat, but the plan weakens the plants much more than placing hand-lights or small frames over strong established clumps out-of-doors, and as they flower without any artificial heat at midwinter, there is really no need to hasten their blooming, and few plants suffer more from root lifting than these.

DELIZIA MARSHII is one of the most floriferous of white flowering plants, all the young shoots of the preceding season's growth being complete wreaths of bloom. If cut down close to the pots after they cease blooming, and kept under glass until June, they will have developed a good head of young shoots, and may be planted out-of-doors in good soil, and kept well supplied with water to perfect their growth; they will now inveshel their foliage, and should be lifted and potted preparatory to introducing to gentle heat, and by introducing a few in succession, they will keep a supply from February until June.

LILIUM HARRISI, one of the very best of White Lilies, may be had in bloom over a large part of the year, but about Easter is the best time for flowering it well under glass. For that period the bulbs should be potted at once; one large bulb in a 5-inch pot does well, and placed in a cool-house until rooted, and then placed in a temperature of about 55 degs., they make splendid heads of the purest of white trumpet-shaped Lilies.

LILY OF THE VALLEY is such a universal favourite that it is always acceptable, and finds a ready sale. The main thing to ensure fine heads of bloom is to have large, plump crowns, similar to those imported, but they can be grown equally as fine at home, if the crowns are planted out singly in rows 1 foot apart, and 5 inches in the row. They may be lifted now, all small crowns being saved for planting out again, and the largest ones potted or placed in boxes of rich soil. They require rather a high bottom-heat, and should be buried in Cocoa-fibre, and kept quite moist until they push up at least an inch; then gradually inure them to the light, and when expanding their flowers place them in a cool-house, to harden off the foliage, which greatly enhances the beauty of the spikes of bloom.

GLADIOLUS "THE BRIDE" should be potted up at once, placing half-a-dozen bulbs in a 6-inch pot. Keep them in cool-house or frame until they are well-rooted, and the tops in full growth; then place in warm-house to flower.

"GERANIUMS," single and double whites, are very useful, and plants that were cut down in August will now be covered with young shoots, which will flower freely if set on shelves near the glass in a warm-house, with rather a dry atmosphere.

HYACINTHS (Roman) only need very slight heat to bring them into flower at Christmas, if potted in September, and will flower in cold

house or frames in February and March. The best of all bulbs for those who have no heated houses.

SPIRÆA JAPONICA must be potted at once and placed in cold frames. As soon as rooted they can be transferred to more heat. Plenty of root moisture is the great thing to ensure success with Spiræas, as they are nearly aquatic.

TULIPS, of the early kind, such as *White Van Thol*, flower freely quite early if potted in October, and when well rooted placed in warm-house or where a little bottom-heat is available. *La Reine* is a fine kind for cutting. *J. Groom, Gosport.*

CHOICE SHRUBS FOR FORCING.

AZALEA MOLLIS AND ITS VARIETIES.

The natural disposition of these Azaleas to bloom early is an advantage, as on account of this tendency they require less forcing. There is one thing connected with the forcing of these plants that should be borne in mind, which is that they should not be hurried into bloom by subjecting them to a high temperature, as, if so treated, the flowers do not last half the time either when cut or on the plants that they will if brought on slowly. This is what occurs with the flowers of most things when hard forced, but more so with the mollis Azaleas than the generality of plants. Large numbers are raised from seed, but they can be also readily propagated from cuttings. Plants that have been forced early, if kept in a little warmth after their flowering is over, soon break into growth that affords cuttings early in the season, so that there is time for them to root and get established during the summer. When the wood of the young shoots has got firm enough—that is, in a similar state to that which is used for cuttings of the Indian varieties of Azalea—they will strike in a few weeks, if kept close and moist in

and moist, to make all the growth possible. Those I raised in the way described from cuttings produced by early forced stock made nice little plants, with several shoots each before autumn; the pots were plunged in ashes during the winter in the frame they occupied in summer, covering to keep out frost. In March they were turned out of the pots and planted in a bed made up of peat, sand, leaf-mould and a little rotten manure, the points of all the strongest shoots being cut away before they began to move, the effect of which was that they were as full and compact in growth as possible. Some flower-buds were set in autumn, but another season's growth was given them before the plants were taken up and potted, at which time they were so full of buds that when they came into bloom the flowers all but hid the wood. The treatment described may seem to entail a good deal of labour to bestow on a hardy shrub, but there are few things that give a better return for the attention they receive. When these Azaleas are forced, like most other hardy shrubs, the plants are often very badly treated afterwards; when the flowers are off them they are crammed into any out-of-the-way corner, not unusually out-of-doors, exposed to the cold cutting winds and frosty nights, and this after having been subjected to the exciting influence of a temperature higher than they like. The plants forced are mostly not larger than will admit of their being grown on and prepared for doing duty in the same way a second time.

To prepare them for this as soon as they are out of bloom, all the shoots should be cut well back, after which the plants ought to be placed in a cold pit or frame, giving them air in the daytime when the weather is suitable, with as much water as will keep the soil in a healthy state. So managed they will be in a condition for planting out as soon as the cold weather is past. A suitable bed should be prepared if the natural soil is not such as will suit them. They are fond of peat, but they will thrive in good free loam, if not too sandy. As a matter of course, plants that have been forced will not move nearly so freely the summer following as others that have not been so treated; but the second season, if all goes well, will see them quite recovered, so that they will make plenty of growth and mature flower-buds in quantity, that will make a display much exceeding that which is obtainable from smaller examples. One great advantage which these Azaleas possess is that they are equally adapted for pot culture by those who have no place where a higher temperature than that of a greenhouse is kept up, as they are for forcing, as if the plants are potted in autumn and at once moved to a greenhouse, they will bloom to perfection at the end of winter and beginning of spring. So managed, the flowers naturally have more substance in them, lasting proportionately longer, whilst the much-prized pink tint which many forms of the plants possess is more intense.

Flowers of *Azalea mollis*.

an intermediate temperature. As soon as the cuttings begin to grow the points must be pinched out. It is essential to attend to this in good time when the plants are required for flowering in pots, as they should be as close and compact in growth as they can be got; for on this depends their ability to produce the most flowers on small plants. Directly the little plants have got well rooted, move them into 3-inch or 4-inch pots, and transfer them to a cold frame or pit, where they must be encouraged, by keeping them moderately close

5029.—Bulbs in pots.—All the subjects you mention will bloom the second year if left in the pots they now occupy; but not so well as in the first year, and probably not at all if they are not well cared for. Unless you are prepared to devote some time to them after they have gone out of flower you had better not keep them over for another year. The treatment they require is that the foliage should not be injured from any cause, and that the roots get sufficient moisture to keep the soil moist until the leaves die down of their own accord.—*J. C. C.*

—The better plan, of course, is to take the bulbs out of the pots and keep them in a dry place; but if you do not force them hard, really only letting them come into bloom naturally almost, you may for one year let them remain in the pots, particularly the smaller kinds, such as *Snowdrops* and *Chionodoxas*.—*C. T.*

—If carefully managed most of the bulbs named would flower in a window year after year; but they must have attention with water after flowering till the growth has ripened, and they should be repotted in fresh, sweet soil early in autumn. Of course, such bulbs will not force so well as those newly imported.—*E. H.*

5017.—A greenhouse wall.—You might cover the wall with Cork if you like, but I much prefer such things as *climbers*—*Ficus repens*, which makes a surface of deep-green leafage, the beautiful *Plumbago capensis*, and its variety *alba*, *Lapageria rosea* and *L. alba*, or you can build up a sort of rockery, and plant in varieties of fine-leaved *Begonia*, *Maiden-hair Ferns*, and many other kinds. I was in quite a cold house

the other day—at least, only sufficiently heated to keep out frosts—and the fine-leaved varieties of *Begonia Rex*, besides a number of such Ferns as *Adiantum emarginatum*, were in full beauty. You could also grow the *Lady's Slipper* (*Cypripedium insigne*), which would succeed under such conditions.—C. T.

— Except the affording a harbour for insects, such as woodlice, &c., there is no objection to doing as you suggest—indeed, it is a very common practice, and if plenty of moisture is supplied the results are, as a rule, good. There are plenty of suitable subjects for planting in the crevices or pockets, including varieties of *Pteris*, *Adiantum*, and other Ferns, *Isoplepis gracilis*, *Panicum variegatum*, *Tradescantia zebrina* and multicolor, fine-folaged *Begonias*, &c. If the whole is kept moist, insects will be much less likely to be troublesome.—B. C. R.

— A greenhouse wall covered with Ferns and creeping plants is very pretty, but to a certain extent *Virgii Cork* does encourage insects, and the continual dampness weakens the wall to some extent. For such a purpose the wall should not be less than 14 inches thick. Pretty well all the smaller greenhouse Ferns and Mosses will grow in such a wall, and in addition *Anthericum variegatum*, *Coprosma Baccata variegata*, *Enklia japonica variegata*, *Pennis repens*, *Dactylis glomerata variegata*, *Pestiva glauca*, *Leucophyton Browni*, *Sedum carneum tricolor*, *S. Sieboldi variegatum*, and *Vinea elegantissima* may be used.—E. H.

7011.—Chinese Primulas and Deutzia gracilis.—The best thing to fertilise single Chinese Primulas is a small camel's-hair pencil, which can easily be passed down to the pollen-bearing organs, and transferred from flower to flower. It must be done when the pollen is dry—about eleven o'clock in the forenoon. I have generally had a better crop of seeds from blooms fertilised later in the season than now, and for that reason I generally keep the later-blooming plants for seed purposes. *Deutzia gracilis* may be easily propagated from the young shoots in heat in spring; but a better way of getting up a stock is to plant out a number of strong bushes rather deeply in a bed of light, sandy soil. Every stem will then form healthy roots round the base.—E. H.

— These must be crossed with a camel's-hair brush, inserting the pollen from one to the other, selecting, of course, colours that are likely to produce offspring of some interest and value. One must be very successful nowadays in the hybridising of Chinese Primulas to get anything distinctive or an advance on varieties already in cultivation. In crossing, aim at getting good colours, fine form in the individual flower or "pip," and a robust form that is crowded with flowers, strong, sturdy, and the foliage of robust character. After hybridising place the plants on a shelf by themselves and in a sunny corner, so that the pots can ripen up well. Be careful to give ample water.—C. T.

— The simplest way of getting Chinese Primulas to seed is to choose those plants which flower late in the spring, and stand them out-of-doors. If you have only a few plants to deal with you may take them out of the greenhouse in the morning and move them back again at night; the insects will then fertilise the flowers sufficiently to obtain plenty of seed. I have seen many scores of these plants in the open air at the beginning of May, with only a mat placed over them at night to protect them from frost or heavy rain, and they have produced more seed than those plants that were manipulated upon with a camel's-hair brush and had the protection of a warm greenhouse. A few plants stood on a shelf well up to light and air in a greenhouse in the months of April and May will generally furnish sufficient seed for one's own use. Fairly hard young growth of *Deutzia gracilis* will strike freely during the summer in a close frame if they are kept watered and shaded.—J. C. C.

7027.—Forcing Lily of the Valley.—Leave the pots in the hot-bed until the growth is 4 inches or 5 inches high and the flower-buds just appearing, then clean them over (of course, the crowns will have been buried some inches deep in fibre) and bring them into a warm-house or pit at 69 degs. to 70 degs., exposing them gradually to the light, and by the time the leaves are green the flowers will be expanding. They need to be kept in this condition by the year.—B. C. R.

PALMS FROM SEED.

At no time were Palms more popular than they are at the present day, and consequently large importations of seeds reach this country by means of which the supply is kept up. Not only do our nurserymen import seeds for their own stock, but large numbers are frequently offered for sale at the London auction rooms, and as a considerable quantity has been announced for distribution in this way, a few words as to their general treatment may not be

"Bungalow" or "Cabbage" Palm (*Scaevola elegans*).

out of place. The all-important consideration is to obtain good seed—that is, with the germ in a plump state, and ready to start into growth when placed under favourable conditions, for in the case of many kinds if the seed has been kept too dry or from other causes, the germ will shrivel up, while the body of the seed remains quite fresh and sound, and to anyone unacquainted with this peculiarity it appears to be in very good condition. With the more rapid means of transit and superior mode of packing, the seed reaches here as a rule in better condition than was formerly the case. The usual way is to pack the seeds in dry earth—that is, a layer of fine earth—then a layer of seeds till the box is filled, when of course the seeds will be perfectly air-tight, and, generally speaking, they reach this country in good condition.

RAISING THE PLANTS.—In sowing the seeds, whether in pots, pans, or boxes, the soil chosen should be a good yellow loam, lightened by an admixture of coarse sand. All mixtures of peat, manure, or leaf-mould should be avoided, unless the loam is of too heavy a consistency, when a little well-decayed leaf-mould will be of service. It is better to pass the soil through a sieve with half an inch mesh, as the young roots are not so liable to be injured when potting the seedlings. In preparing the pots, pans, or boxes for sowing, fair drainage should be ensured, but Palms do not require nearly so much drainage as some subjects, all that is needed being to allow the surplus water to drain away. The soil must be pressed down moderately firm and made level; then when the seeds are sown care must be taken that they are

not overcrowded, and they should be covered with soil to about their own depth. Until the young plants make their appearance above ground light is, of course, not essential, so that the boxes may be stood underneath the stages or in any out-of-the-way place, provided a good heat is maintained and the soil not subjected to any great extremes either of drought or moisture. The very best position is a bed of Cocoon refuse with a gentle bottom-heat, in which the pots or pans should be plunged, when if the seed is fresh it may be reasonably anticipated to

soon germinate, though in this respect many Palms behave in an erratic manner, for frequently a few will make their appearance quickly after sowing, while the bulk will not germinate till a long time after. When the first leaf is well developed is a good time to pot off the young plants, for which purpose the soil should be the same as that above recommended in which to sow the seed. For

The first potting it will be found an advantage to sift the soil as for sowing. For most of the generally cultivated Palms small pots known as thumbs are large enough, and if one good piece of crock be placed in the bottom of each pot, it will afford sufficient drainage. As the seed remains for some time attached to the

young plant, a good general guide as to the depth it should be placed in the soil is thereby furnished, and that is in potting to place the young plants at such a depth that the seed just rests on the surface of the soil. The compost employed must be pressed down moderately firm. Should the roots be as all matted together, they must be carefully disentangled, or if broken or bruised however slightly, the result is likely to be the death of the plant. After potting and a watering sufficient to settle the soil, the pots should be plunged in a gentle bottom-heat, when the after treatment will consist in watering when necessary and in syringing more or less frequently, according to the season of the year and the weather experienced. It should be borne in mind that a humid atmosphere is favourable for most Palms, being very conducive to rapid growth. As repotting is necessary, much the same kind of soil may be used, except that a little well-decayed manure will in the case of the stronger growing kinds be of service. Palms, as a rule, very much resent being over-potted, and to the uninitiated it is surprising what effective specimens can be grown in pots 5 inches or 6 inches in diameter. Of course, as the pots get full of roots an occasional stimulant is necessary to maintain the foliage in good condition, and the soil must not be allowed to get dry, as if this happens the foliage is very apt to acquire a sickly hue. When in small pots and they are full of roots, it is almost impossible to overwater them, provided the surplus water is able to drain away. Where Palms are kept in the dwelling-house, a very important factor towards maintaining them in good condition is to frequently sponge the leaves with tepid water to remove the dust, which quickly gathers on the foliage. As the roots of most Palms are of a deep-descending nature, they, as a matter of course, coil round the bottom of the pot, and when repotting takes place, these roots should be allowed to remain undisturbed, as if injured it may prove fatal to the plant. The principal insect pests from which Palms suffer are different forms of scale, some of which are more troublesome than others; but in the case of any of them the object aimed at should be to clear them off directly they make their appearance, as if allowed to effect a thorough lodgment on the leaves they are very difficult to eradicate without injuring the tender, unfolding foliage.

VARIETIES.—Of Palms that are used for decoration in a small state may be especially mentioned the different *Kentias* now so extensively grown by all our nurserymen, *Lataria borbonica*, *Cocos Weddelliana*, *Geonoma gracilis*, *Scaevola elegans* (see cut), *Arcaea lutescens*, *A. sapida*, *A. Buerei*, and *A. Verschaffelti*, *Phoenix rupicola*, several species of *Chamaerops*, *Rhapis thalictroides*, and *Corypha australis*. As several of these will do well in a greenhouse temperature, they are suitable for a dwelling-house. But in raising them from seed, even the hardiest are much

better if kept during their earlier stages in the stove, as they make much more rapid progress, and consequently form effective specimens in much less time than if they do not get the additional heat when young. The hardest of all the above are *Chamaerops exelsa* and *C. Fortunei*, *Corypha australis*, and *Rhapis flabelliformis*. This last is an exception to the others in its method of increase, for seeds are rarely obtained; but as a set-off, it pushes up suckers freely, which when sufficiently advanced can be taken off with their attendant roots and replanted. H.

5012.—**Heating a greenhouse.**—I have used the earthenware pipes for lines many a time, but so far never for hot water. I recently, however, saw part of an apparatus taken from a house that had been heated in this way, and the pipes were all sound and tight. I really do not see why it should not answer, and, indeed, intend to try it myself one of these days. If the joints are carefully made with fresh Portland cement the whole will be quite tight, and ought to answer satisfactorily, but I should endeavour to avoid getting the pipes overheated at any time, the water certainly ought never to boil. With the tank not more than a couple of feet higher than the pipes, and one or more good sized air-pipes, there would be no pressure in the pipes likely to do any harm.—B. C. R.

5015.—**Cost of heating a greenhouse.**—This is a question that has troubled the minds of a good many people before now, and is likely to do so for all time, because, as no man can foretell the kind of weather we are going to have, it is impossible to estimate the probable cost of fuel to heat a given space. Six weeks of frost in the dead of winter will make all the difference in the calculations. Even without actual frost, if a low outside temperature prevails for several weeks, that will make all the difference in the consumption of fuel. So will also the form of houses, especially if they are high ones, and the span-roof form is more expensive to warm than a lean-to. "Scotia" will understand that the superficial area to be heated is a consideration that cannot be ignored in framing an answer to his question. Employers of gardeners often think that more fuel is consumed than is necessary; but a little consideration will show that they are mistaken, because if a higher temperature is maintained than the plants require it would do them injury, and no skilful man would so act against his own interests.—J. C. C.

5022.—**Covering for a stage.**—Yes, pot plants standing on an open stage just over three rows of hot pipes are sure to get badly dried at times. Your best plan will be to lay down sheets of the galvanised corrugated iron, or stout slates would do, covering them with 2 inches or 3 inches of fine "ballast," beach shingle, or gravel (not ashes), and stand the plants thereon. The material should be kept moist by frequently syringing between the pots. If you give the iron a coat of hot limo before using, it will last all the longer.—B. C. R.

Corrugated iron will make a good covering on the stage. Run a line of angle iron back and front of the stage for the corrugated iron to fit into. Sand or fine gravel will do to stand the pots on.—E. H.

You could use corrugated iron, and it is done under such circumstances. Put the plants upon shell or small stones, which will retain the moisture fairly well. During the whole year it will be very necessary to look after the plants well, otherwise they will soon wither.—C. T.

Asparagus plumosus as a basket plant.—This forms a splendid basket plant. To grow this plant well it must not be cramped at the roots, my baskets being quite 2 feet over. The plants, as they grow, climb up the chains by which the baskets are suspended, and also depend all around, forming altogether beautiful objects. Last season I saw some magnificent baskets of this plant in the large winter garden at Witley Castle.—A.

4973.—**An unheated frame.**—"Lady's Slipper" will find the following (orchids do well in an unheated frame: *Cypripedium calceolus*, *C. spectabile*, *C. macranthum*, and *Epipactis gigantea*. I have had plants of the above in a similar position for the last five years, and they grow well and bloom well.—AN ORCHID LOVER.

5018.—**Hoya and Dracena, &c.**—Supposing that the Hoya is the ordinary *H. carnosa*, or Wax-flower plant, little difficulty should be experienced in wintering this in a sitting-room; in fact, it makes an excellent window plant. It should be kept nearly dry at the root until growth recommences in the spring, and, indeed, in severe weather, if allowed to become quite dry, will be all the safer, and also more likely to bloom freely next season. *Dracena terminalis*,

belonging to the variegated-leaved section, is more delicate, and really needs the warm, moist atmosphere of a stove. Keep the plant as warm as possible, and the soil moderately but not too dry, and it will probably survive, though it is almost sure to become more or less shabby. *Polystichum angulare* is a hardy British species, and thrives best in good sandy loam, made fairly firm. It is nearly or quite deciduous, so must not be overwatered while at rest.—B. C. R.

FRUIT.

SOME GOOD DESSERT APPLES.

PERSONALLY I am strongly of opinion that Dessert Apples approaching coarseness are objectionable, and certainly do not give the greatest satisfaction on the dining-table. Coarseness, I know, is a term that can rarely be applied to Cox's Orange Pippin, Margil, Ross Nonpareil, Fearu's Pippin, and such like, but Ribston Pippin, Gravenstein, Bleuheim Pippin, Adams' Pearmain, King of the Pippins, and other popular varieties that could be named are frequently seen in prize-winning collections of a size qualifying them for cooking rather than for dessert. There are plenty of really good medium-sized to small-fruited sorts available for cultivation other than the dozen or so varieties on which there has been such a great run during the past decade, to a few of which I will direct attention, taking them somewhat in alphabetical order:—

AROMATIC RUSSET is largely grown in the south-western counties, but, according to my experience, not often met with elsewhere, yet it is a first-class variety. It succeeds well under any form of training, good pyramids being easily grown, while there are few more reliable as regards free bearing. The fruit is of medium size and nearly covered with russet, therefore not particularly attractive in appearance, being, however, of excellent flavour, and,

sized, prettily-coloured fruit, which are of excellent quality late in August.

BRADDICK'S NONPAREIL I have frequently praised in these pages, being of opinion that it is one of the most valuable Dessert Apples in cultivation. In habit it is somewhat straggling and slender, horizontal or espalier training answering best, though fairly good bushes, pyramids, and standards may be grown. It is one of the surest bearers, the fruit being of medium size, much flattened, and very distinct. When ripe it is fairly attractive in appearance, of excellent quality, and keeps admirably. The season extends from November till late in April.

COURT DE WICK, a Somersetshire Apple, and at one time a favourite variety, is now much less grown, owing, doubtless, to the smallness of fruit. It is a juicy, however, that such a pretty and richly-flavoured variety should go out of cultivation. It is not a very strong grower, by no means fastidious as to soils or position, and a sure bearer. The season of this superior Dessert Apple extends from November to March inclusive.

GOLDEN KNOB, of which an illustration is here given, is distinctly a Kentish Apple—at any rate, I have never met with it much elsewhere than in Kent and that part of Sussex adjoining, though why its cultivation should be so much limited is hard to determine. It is excellent either for home consumption or market, keeping good till long after most other varieties are over. Standard or orchard-trees attain a moderately large size and rarely fail to bear well. The variety is also admirably adapted for garden culture. The fruit is somewhat small and completely covered with russet, while the flesh is yellowish-green in colour, juicy, and brightly flavoured. Too often, however, the trees are cleared of their fruit before it is fit to store, the proper course to pursue being to leave the Golden Knob to the very last before gathering, a moderately severe frost doing it more good than harm. If they are dragged from the trees the fruit shrivels badly and is not fit to eat at any time. The variety ought to be at its best from midwinter till April.

GOLDEN PIPPIN is far more common than the foregoing, and though one of the smallest of Dessert Apples, is also one of the best. Every lover of Apples who can afford the space ought to plant a tree of this delicious variety, and would not often be disappointed as to its cropping qualities. The bush or informal pyramidal form of training best suits it, while the fruit is about 2 inches long and the same in depth, rich yellow in colour, crisp, juicy, and agreeably flavoured, being fit to eat in November, and keeping good till the end of March.

GOLDEN REINETTE, another very old and excellent variety, still finds plenty of admirers, and it is to be hoped, will continue to do so. On our cold clayey soil it fails badly, but where the subsoil is of a more gravelly nature the tree attains a good size and crops heavily, garden culture suiting it well. The fruit is medium-sized, very pretty, and (when ripe) juicy and richly flavoured. In season from November till well into April.

KERRY PIPPIN, a small and pretty variety, ripening during September and October, still has plenty of admirers, and fully deserves that distinction. It is amenable to any form of training, and seldom fails to be productive.

LAMP ABBEY PEARMAIN.—This, a few years ago, was usually included in most selections of Dessert Apples, but, being small fruited, I am afraid it is likely to drop out of cultivation. The variety is adapted for either orchard or garden culture, and for any form of training. The fruit colours prettily, and when in season, or say from midwinter till April, is decidedly superior in point of quality.

LORD BURGHLEY is much less well known, but is equally worthy of being largely grown. The tree is inclined to canker somewhat on heavy soils, but in spite of this failing it should be given a trial everywhere. It can be trained as a pyramid, and makes a good dwarf or corner on the Paradise stock. With me it seldom fails to

Fruiting-branch of Apple "Golden Knob."

as its name implies, highly perfumed. In common with most other russet-cotyled, yellow-fleshed Apples, care must be taken not to gather the fruit too early, or otherwise it will become tough and flavourless. The proper season is December to February inclusive.

BENONI is even less well known, but, all the same, it is one of the best flavoured second early Apples I am acquainted with, and is a great favourite with that experienced pomologist, Mr. W. Pragnell, of Sherborne Castle. It is said to be of American origin, and both in the mids and cordons bear good crops of medium

hear well, and if not gathered too early will keep fresh and good till most Apples are over. The fruit is somewhat dull in appearance, but it is very juicy and of good spicy flavour.

PEARSON'S PLATE AND SAM YOUNG are both good growers, very prolific, small-fruited, and of excellent quality. The latter variety is in season from November to February, while the former lasts about a month longer.

SEEK-NO-FURTHER is not often met with, but it is quite deserving of being preserved. It forms a medium-sized tree, its habit suiting small gardens well, and in most favourable seasons crops satisfactorily. The fruits are somewhat oval, very richly coloured, and tender and pleasing. Carefully stored, the season extends from November till March.

WYKES PRINX is generally recognised as being a very reliable and good Apple, but its smallness militates against it. The tree grows moderately strongly and may be grown under a variety of systems. Though not particularly showy, a well-selected dish looks well on the dining-table, and no fault can be found with the quality. It is in season from November till April. W. I.

5023.—Pear-trees not growing.—One sentence you use in your inquiry appears to me to explain the cause of your trouble. You say two years ago you had the meadow trenched up. Now, as the word trenched is understood by gardeners, it means that you placed the good surface soil at the bottom and brought the inferior to the top. If this is what you have done, it is sufficient to account for the trees not growing; the soil is too poor for them. To make a permanent job of it, you cannot do better than trench over the ground again, and bring the good soil to the top. Probably a heavy dressing of rotten manure placed on the roots after the surface soil is laid on one side, will start the trees into growth, but you will have to repeat this operation every year in a sandy soil until the roots have found their way down to the turfy soil below. You have acted wisely in not pruning the trees, nor should you do so until they have made sufficient growth to require it; not, in fact, until it gets crowded or unlimb in length.—J. C. C.

Give the Pear-trees a good top-dressing of rich manure. They require something better than sand to grow. E. U.

5019.—Treatment of Cherries.—Prune the shoots back to within five eyes of the base where it was lopped; this will allow of two branches being made on each side and a leader in the centre. By this means the trees will be furnished with branches properly from its base. When maiden trees, such as the one quoted by "Pine," are not cut hard back the first year, the tree eventually becomes leggy, owing to the non-development of the buds nearest the base, consequent upon the flow of sap going direct to the upper part of the tree.—S. F.

The Cherries should have been cut back before. It would have been better stopped when about 18 inches high, and the laterals made labour laid in. However, cut back now to within half-an-inch buds of the bottom, and next summer train all the shoots in.—E. H.

Vine snags.—It is difficult to find a more appropriate designation for the long, crooked, and ugly snags found so frequently on old Vines. There seems to be no reason why these long snags should be left on rods, but it seems to be a practice with many growers. In time the product is small, thin wood and very poor bunches. If the process of pruning compels the formation of these long snags after a few years' fruiting, would it not be better ere the evil gets too great to carry up new rods from the base of the old ones, more frequently cutting away the whole of the snags one-half or one-third the length of the old rod, according to the run of the roof, tying the new rod in to fruit where the snags have been taken off, and so continuing to extend it the following years? Thus instead of seeing, as is so often the case now, Vines all snags, these old rods would be replaced every few years.—B.

5078.—Flies on fruit-trees.—Sprinkle the wall with a strong solution of Sunlight soap, 3 oz. to the gallon, adding a whiff of paradisal oil to each gallon. The mixture will not injure the trees.—E. H.

5067.—Worms on a lawn-tennis ground.—Sprinkle the ground with blue-water made from fresh lime. Repeat as often as necessary. Another plan of a more permanent character would be to take up the turf and put as much of chunder-rot as you can get on the turf on the sides.—E. H.

THE MAIDEN'S WREATH (FRANCOA RAMOSA).

THE subject of the accompanying illustrations should be found in every collection of plants of any pretensions. It is as valuable to the amateur with only a small greenhouse as it is in larger numbers for decorating conservatories. By some it is found to be tolerably hardy, but the position chosen for it in the open air should be a protected one as well as fairly dry. In the milder parts of the country it may with these precautions be depended upon in

Maiden's Wreath (F. ramosa) in a pot.

average winters. It is a Chilean genus belonging to the Saxifrage family. As a decorative plant for grouping it is peculiarly adapted whilst in flower. Spike succeeds spike, and these as a rule send forth laterals, thus keeping up a long succession of bloom. My practice is to grow it in a cool-house all the season; this is not necessary when not in flower. A cold frame or pit will do provided there is not an excess of damp during the colder season. At other times it may be stood out-of-doors with safety, but when in flower it is better preserved in good condition if under cover. In my case the temperature frequently falls below 40 degs. in the winter, and the plants are usually a long way from the glass, yet they do remarkably well under this latter unfavourable condition. The plants can be kept in good health for some years at a stretch, and as they increase in size they will be found equally useful for large houses. A fresh potting each spring should be given. The soil should consist chiefly of good friable loam with leaf-soil and sand. Firm potting is preferable to a loose condition of the soil, keeping the plants in a healthy state for a greater length of time. Propagation can be effected either by cuttings or seeds. Cuttings, I find, strike best in the early spring, each one being placed singly into a 2½-inch pot, with a liberal amount of sand. In a gentle warmth, but not too close or moist, these cuttings will soon strike. As soon as well-rooted, one shift ought to be given; this will suffice for the first year. The seed is now about ripe from plants which flowered early. To save time this could be sown at once, and the seedlings kept steadily growing through the winter upon a shelf near

the glass. By the spring these will make nice little plants with the possibility of a spike or two of flowers in twelve months. The best display will, however, be from plants at least two years old from seeds. Insects, to all appearance, do not trouble this Francoa, and it is fortunate this is so, for the foliage, being hirsute, is not easily cleansed. The plants when growing freely and showing flower will take a liberal supply of water, with a dose now and then of liquid-manure as an assistance. The illustration on this page shows how well the plant will grow and flower in a pot. The spikes when cut are useful for trumpet vases, and also as a wreath for a lady's hair (see cut, page 361), lasting well. Other Francoas worth growing are F. appendiculata, with deep-coloured flowers, and F. sonchifolia, rose-coloured flowers. H.

ORCHIDS.

ONCIDIUM SPHACELATUM.

IT is now some long time ago since I promised "C. Cameron" I would say a few words upon this species. When I received the flowers from him in the spring of the year I was much put about to furnish all the information asked for, and so the request was overlooked. I quite agree that the species above-named is a very pretty and showy one, and the flowers sent by "C. C." represented a very good one, reminding me of a form which I used to grow years ago, which was called *Phelpsiannum*; but this, I think, was only a local name, and I do not see it recorded anywhere. *O. sphacelatum* is a very free-growing plant, and it was sent to this country from Guatemala more than fifty years ago, and I do not think it has ever been lost to cultivation since. As "C. C." says, it is a splendid Orchid for growing with other stove-plants, as it thrives well in such situations, and flowers in profusion. Now, I like to see grow the majority of Orchids, for why they should require a separate house to grow in I cannot think. The only thing I have to say against the growing of these plants in a house with a mixed collection is that they are apt to get overshadowed and smothered up by the foliage of the other things that are not Orchids; but this can be obviated by the owner if he takes the least trouble with his plants. As I have before remarked, *O. sphacelatum* is a free-growing plant, and it soon attains to considerable dimensions, and if it grows to an inconvenient size in the course of a few years, it can easily be cut through and divided, whereby two or three specimens are produced. These should be potted in well-drained pots, and be placed in a compost consisting of fibrous peat and Sphagnum Moss. It likes an abundance of water when growing, and even when not in an active state it should have sufficient water to keep the bulbs in a plump condition. This is a point that wants watching, for if this is done it is surprising the difference that will be seen in two plants that have been treated in the two different ways. When I was a young man amongst Orchids it was always the right system to give the Orchids a thorough good drying as a resting season, but as I grew to be my own master amongst the Orchids I determined to see if better treatment would not make these plants present a more pleasing appearance, which I did, and here record it for the benefit of my readers, and a fair amount of water through the winter months will prevent the bulbs putting on that starved and wrinkled aspect which they assumed under the dry system which used to be given them some few years ago. This is a plant which is a special favourite with ladies on account of the long spikes being much branched, and the short branches forming such elegant little gems for their own cutting, and this I would always grow a plant or two for—it makes such a lot of difference if a lady can cut her own flowers. MATT. BRAMBLE.

CATTLEYA WALKERIANA.

THE statement made to me by "James Walker" only goes to prove that he is either a young grower of Orchids or that he has not made them a study, for he says, in sending me a flower of this plant, "What is the cause of it going wrong in the flowering stem?" Well, "J. W."

must know that this is a feature of the species which used to be considered peculiar to this plant, only the same as I have pointed out in the case with *Epidendrum Standfordianum*; but one or two others have appeared which have the same peculiarity. The flower sent to me is a very deep-coloured one, almost as deeply coloured as a good form of *C. nobilior*, which flowers in the same manner on a small and weak leafless growth, and which dies away soon after the blooms. *C. Walkeriana* is one of the finds of Gardner, when collecting in Brazil, now upwards of fifty years ago, near the diamond district, and which became known in English gardens by the name of *C. bulbosa*, and which it was long called. It is a free-flowering plant when grown well, the curious shoots upon which the blooms are produced usually bearing a pair of flowers each, and these last a long time in full beauty if ordinary care is taken to prevent water from the syringe falling upon them; the colour of the sepals and petals being rich rosy purple, the petals much broader than the sepals; the three-lobed lip is panduriform, the side lobes being reduced to small, erect, ear-like appendages, which cover the column only at the base; these are deep rosy-purple, the stout column being of the same colour, the front lobe of a rich amethyst-purple, streaked with deeper purple, and at the base it is of a pale yellow. This is an Orchid that requires to be kept warm all the year round, and to have a good moisture in the air at all seasons; of course, what is considered a fair amount in the summer season would be too much in the winter; but as the plant grows near streams of water, and as its roots are thrown out a good bit from the stem upon which it grows, it derives a certain amount of nourishment even in the resting season. I have found the plant to grow and do best upon a bare block of wood, not the thin pieces of wood which nowadays are too often used in trade collections, but on a good-sized block of wood; it does not so much matter what kind of wood, but I think Willow is the best; there should be just enough Sphagnum put upon the block with the plant to keep it moist, and the air should be kept moist. I do not think it is any good to try pot-culture with it—at least, I could never succeed with it treated in this manner—but it may be grown in hanging earthenware pans with just the least bit of peat-fibre and some Sphagnum Moss over the crocks. It is a very beautiful species with a cheerful good-sized flower, and although a little difficult to manage, it is yet always a very desirable plant, but it is not one I should recommend the young beginner to try.

MATE. BRAMBLE.

LADY'S SLIPPER ORCHIDS (CYPRIPEDIUMS).

THE *Cyripediums* are plants well suited to the wants of amateur gardeners, for they do not require any great amount of artificial heat or anything more than ordinary appliances to grow them to perfection, and they flower very freely, and last a long time in good condition, and few flowers find a readier sale. Many gardeners in private places where the surplus produce is sold have told me that they get more inquiries for these than any other flower they grow. Certainly, some of the new kinds are expensive, but the older kinds, such as *C. insigne*, *C. barbatum*, and others are not only reasonable, but are readily increased by division. They do well in pots or pans, in a mixture of peat, Sphagnum Moss, and charcoal, and may be grown well under the shade of Vines or other fruit-trees, and at this period of the year, when a good many will be in flower, they are quite at home in the conservatory or stove-house, where rather a dry temperature is maintained. There is something of charm about the culture of Orchids, and many amateurs would like to embark in their culture if they were not deterred by exaggerated notions of the expensive appliances in the shape of tropical stove-houses, hanging-baskets, &c.; but these are really useful plants that repay any care bestowed on them, with handsome, lasting, and beautiful flowers, and doubtless many growers have been disappointed with their first experience of Orchid growing, for all Orchids are by no means suited to amateur cultivation, and can only yield disappointment to anyone that embarks in their culture.

J. O., Hants.

FERNS.

THE BRITISH HART'S-TONGUE FERN (SCOLOPENDRIUM VULGARE).

This plant in its normal condition cannot be mistaken for any other Fern. One species only inhabits Britain, but this is very widely distributed. It crops out more frequently in spots where chalk predominates in the soil. It has broad, simple fronds, which vary from a few inches to some 2 feet or 3 feet in length; and only the other day I had a specimen sent me by a friend which I had not before seen. It was the variety *reniforme*, having fronds about 3 inches long by 2 inches in breadth. This is one of the innumerable varieties into which this Fern has passed many forms having their fronds ramified and crested quite out of all conception; and it is to the beauties of many of these forms which I would draw the attention of my many readers. At this season of the year they are specially to be considered, because their fronds are persistent and evergreen, standing in the open fernery without the slightest protection; but this suits them better if slightly protected from the north and east winds. The bright and shining green of their fronds always presenting a cheerful appearance, whilst if grown as pot plants they are equally beautiful, and are always available for hall and room decoration; and they may be used with a good deal of propriety for the ornamentation of window-boxes during the dull, cold days of winter, when their roots are protected from the sharp frosts. I think the only position in which I dislike to see these Ferns is the outside of a window in the winter as pot plants, for in such a situation they stand but a poor chance of thriving long. The frost kills their roots, and the fronds become crippled and torn, and they are no longer an ornament in the position named, and have to be cast on one side. Now, some of my readers may be somewhat astonished at this and say that being a British plant, and a common one too, why will it not succeed as a window plant? And so it will when protected by the soil of a window-box, but not to stand upon the open sill in a bare,

OUR READERS' ILLUSTRATIONS: Spray of Maiden's Wreath on a lady's head. Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Ellen L. Coles, Elford, Staffs. (See article "The Maiden's Wreath," p. 550.)

unprotected state. It is beyond a plant's endurance, be it ever so hardy; for its roots, which in a state of nature live in the soil, here, in a state of cultivation, become frozen and die. They are admirable ornaments in the cool fernery, slightly protected, but without any heat whatever. The best soil to plant them in is some good friable loam, mixed with some sand and with some calcareous soil in it. They should be potted firmly, leaving room for a good soaking of water, of which they like a goodly quantity during the growing time, as well as frequent light airings overhead; but during the winter, if they stand out in the frames, the pot

plants should be carefully and frequently looked over to prevent slugs and snails from eating and defacing the fronds, and in the open fernery all sorts of things should be laid down to trap them. The following kinds are all beautiful. I cannot give any description of these, because it would be too similar; but any person having a good collection would soon recognise them. The following firms keep the best collections of Ferns at the present time: Backhouse, of York; Birkenhead, of Sale; Bull, of Chelsea; May, of Tottenham; Veitch, of Chelsea; and Williams, of Holloway. The following two dozen kinds are all good and worthy of general cultivation: *S. capitatum*, *contractum*, *Cominsii*, *corymbiferum*, *crispum*, *cristatum*, *crispum fimbriatum*, *eristatum*, *digitatum*, *grandiceps*, *jugosum*, *miguete furens*, *Kelwayi*, *lacinatum*, *Macleodsoni*, *maximum*, *ramo - cristatum*, *ramo-marginatum*, *reniforme*, *sagittato-cristatum*, *Stansfieldi*, *Morgani*, variable, and *Worlei*. J. J.

DECIDUOUS FERNS.

MORE attention might very advantageously be given to this section; most of them die off towards the winter, thus allowing more room for other things—in itself an advantage in many respects. These Ferns are not probably so abundant as they would otherwise be, simply because they are deciduous. This may be attributed in some instances no doubt to non-attention when they become shabby; not that they want a great amount of care, but they should not be allowed to get too dry. If the soil be kept in a happy medium the plants will be right enough, and will after a rest start with renewed vigour. Any attention that may be needed in the way of potting should be seen to as soon as the young fronds begin to make a move; if, however, my increase by division is necessary, that should be done a little sooner, so as not to cause any injury. As the growth begins to rise away from the soil see that the plants are kept well up to the light to prevent the stems drawing up abnormally long and slender. When the first fronds are more fully developed the majority of these Ferns will take water very freely, affording in this respect quite a contrast to the previous or dormant treatment, but as signs of fading and disposition to cease growing are apparent, then withdraw the water gradually. These deciduous Ferns are useful for all purposes to which a Fern can be applied, whilst as regards temperature they can be had from those suited to the stove downwards to the cool-house and cold pits. Of all these Ferns there are none, I think, to surpass

LEUCOSTEPIA IMMERSA, which in appearance very closely resembles *Davallia Mooreana* unless it be minutely inspected, when the difference is apparent. It is of smaller and more compact growth, making beautiful little plants in 5-inch and 6-inch pots. If larger plants are needed, then I would advise pans in preference to pots. Another excellent way of growing this lovely Fern is in baskets. These may be of wire, of rustic work, or of pottery-ware, in any of which they thrive well and make a mass of roots. The best effect is obtained, in my opinion, with this Fern when grown well exposed to the light. The bronzy tints then assumed cause it to be most attractive, whilst this kind of growth is also the most durable. It is a variety easily increased by division, and there should be no difficulty in obtaining a stock thus or by spores. I note that it is now included amongst the *Davallias* in the "Dictionary of Gardening." *Davallia immersa* sounds quite as well, but one is often accustomed to the older names and does not readily relinquish them. It may be grown in a cool-stove or temperate-house with the greatest success. Another good Fern of this class is

DAVALLIA BULLATA (the Squirrel's-foot Fern), one of the prettiest of the dwarfer species, and one which should find a place in the smallest collections. This also makes a beautiful basket Fern, is easily grown, and as easily increased by division. It is also admirably suited to the fernery for growing upon walls or pillars, or it may be cultivated with equal success in either pots or pans, flat or rounded up as may be desired. This Fern will with good attention in the way of top-dressing remain in good health all the year round, and will keep up. This, however, should be done occasionally, doing away

with the older rhizomes in the process. In small pots it is a very suitable Fern for decoration, whilst for supplying cut fronds it is one of the best that can be grown, the fronds lasting well in the young as well as in the mature state. The smallest fronds make capital material for barking up button-holes.

DAVALLIA ROSSETTA is another good Fern of this class, particularly as a decorative variety for clothing walls, for baskets, and for cutting, giving a good supply of fronds in the autumn, like the foregoing. It may be grown in the temperate-house. *D. lullata* I have kept safely enough when at rest in 45 degs., with 10 degs. or 15 degs. more when growth commences.

Amongst the *Adiantums* there are some which come under this category also.

ADIANTUM FOSCENSEM, a gem amongst the Maiden-hairs when well grown, does best when treated as a deciduous Fern. This species is not nearly enough grown; in fact, it seems to escape notice almost entirely, whilst the larger form, *A. concinnum* latum, comes in for a much larger share of attention, although in my opinion it is not nearly so beautiful; it has size in its favour—that is all. Both of these, but more particularly the type (*A. concinnum*), do best in the warm-slow, where this species makes a beautiful basket-plant.

A. ETHIOPICUM ASSIMILE is another very charming deciduous Fern, casting its fronds in November, and starting into fresh growth again in March. This is essentially a Maiden-hair Fern for the many, being easily cultivated in a cool-house; in fact, it has been known to live out-of-doors through the winter. It makes a very pleasing basket-plant, the creeping rhizomes appearing round the sides and the bottom. The fronds are pale-green in colour, but do not last well in a cut state.

A. AMABLE, also known under the name of *A. Moorei*, makes a beautiful basket Fern, having in this respect the properties of the foregoing species, but possibly in a more marked degree. It is a rapid-growing Fern, nearly or quite (according to the temperature) losing its fronds in the winter. It can be kept in a temperature of 45 degs., but is safer in 10 degs. higher. In the stove it makes one of the very finest of basket Ferns.

A. LUNELATUM is another deciduous species—one also that is of very slender growth. It should be grown as a basket plant, or at any rate suspended if in a pot. Having the property of reproducing itself from the extremities of the fronds, it soon makes a good growth when once it is started. This is also one that requires a liberal supply of water; even when dormant it should not be allowed to dry up. This list of *Adiantums* would not be complete were it not to include

A. PERIATEM, one of the prettiest of all, particularly whilst the fronds are still young. This species may be safely wintered in a cold frame or out-of-doors, even in the more favoured localities. In its wild state it is found in both hemispheres, being widely distributed. For planting out in the cool fernery it is strongly to be recommended. Its hardness has been well tested in some localities, but I am disposed to think too much exposure as a rule would not be beneficial. Shadow planting in particular is not advisable, particularly in cold situations. As a pot plant it can be strongly recommended, lasting a long time in good condition.

LYCOMIS SCANDENS does best when treated as a deciduous Fern, thus affording a suitable opportunity for making a wholesale clearance of any insect pests to which it is oftentimes predisposed. Scale and thrips are the enemies in this respect, and these cannot always be cleared out of such slender growth. As growth ceases in the autumn the plants should be kept fairly dry, then after a time as the fronds become shabby they may all be cut off. By this time, for instance, this may be done, only pot room is then required until young fronds appear again. When required mainly for cutting the better way is to train each frond up a slender string from the early growth, keeping each one to itself, so that it can be readily taken off when wanted. For twining round tall vases, rustic arches, &c., these fronds are extremely useful, particularly when the fertile ones are fully developed. I have seen it grown well upon the back wall of a viney. This was at Normanhurst Court, the country residence of Lord Russell. This species is now more generally known under the

name of *L. japonicum*. The list of deciduous Ferns might be further extended, but sufficient have been named to draw attention to a class which does not receive in very many instances that notice which they deserve. One would be almost inclined to think that the opposite would be the case when so many and varied plants are now wanted for decoration. Certainly they may be cultivated much more, and that with advantage. P.

5032.—**A new greenhouse.**—You may grow a variety of interesting plants in your greenhouse, one of the most beautiful and useful being the *Chrysanthemum*, and by striking the cuttings late you may get flowers until Christmas. I shall not give a selection, as in recent issues of *GARDENING* selections have been given for all purposes, and you must refer to them. Azaleas are beautiful, *A. Borsigii*, *Deutsche Perle*, the old *Fielder's White*, *Chrumer*, *Carmine*, and *Duc de Nassau*. The old *Double White Camellia*, and the varieties *Doonckelari*, *Marchioness of Exeter*, and the white hybrids are useful. Then select also *Fuchsias*, *Pelargoniums* of all sections, *French and Zonal*, the *Tuberous Begonias*, which will keep the greenhouse gay throughout the summer. *Bouvardias*, particularly the double *Alfred Neuner* and *President Garfield*, *Herbaceous Calceolarias*, *Tree-Carnations*, the *Crimson Winter Cheer* in particular, a dwarf, bushy, free-growing variety; *Cinerarias*, *Cyclamens*, *Fritia hyemalis*, the most useful of the *Heaths*, *Epacris*, *Heliotropes*, *Veronica Andersonii variegata*, *Salvias*, and the winter-flowering *Begonias*. Of climbers you may plant *Maréchal Niel Rose*, *Plumbago capensis* and the variety *alba*, and the beautiful *Lapageria alba* and *L. rosea*, whose waxy flowers are very beautiful. On the wall *Ficus repens* is very pleasing, forming a perfect mat of rich-green leaves, and do not forget a variety of Ferns may be grown, such as in the basket the graceful *Nephrolepis exaltata*, and in pots the most useful of all Maiden-hairs, *Adiantum cuneatum*, and *Asplenium bulbiferum*, *Cyrtomidium falcatum*, *Davallia canariense*, a small *Dicksonia antarctica*, *Pteris serrulata cristata*, *P. erecta* and its variety *albo-lineata*, and *P. tremula*. You may brighten the structure in winter and early spring by potting a lot of forced bulbs, such as the *Polyantus-Narcissus*, *Tulips*, *Daffodils*, *Snowdrops*, and *Chionodoxas*, both the pretty *C. Lucifera* and *C. sardensis*.—C. T.

4886.—**Primula obovata.**—To my mind, neither of your correspondents on page 534 have any idea of the poisonous nature of *Primula obconica*. A few years ago I was in a market nursery where it was largely grown. It showed no respect of persons; everyone who had the care of it in a shorter or longer time suffered from its poisonous properties, until it was impossible to get anyone to undertake the charge, and the stock was got rid of. It is not that it causes or aggravates erysipelas in those who are subject to it, but it produces a kind of blood-poisoning and eruption of the skin, which is distinct enough for a medical man who has once had a case before him to recognise it again. It mostly attacks the hands, arms, nose, and lips, the chief danger being in gathering the flowers. I believe the poison to be contained in the fine hairs that cover the flower-stems and leaves, but a doctor who had attended a number of cases stated that the very atmosphere of the house where they were grown was sufficient to continue the irritation. I succeeded in potting a large number of plants without injury by taking the precaution to rub my hands and arms well with tallow before starting. I do not think there is any harm in having a few plants, but the danger is when anyone constantly handles them, as is necessary where they are grown in quantity for market. If this is the intention of "Constant Reader," my advice is "Don't!"—KITT.

—With regard to the poisonous nature of this plant, and the very different opinions given by correspondents in answer to "Constant Reader," Nov. 11, allow me to give my own experience in the matter. In 1892, when I was matron of a large charitable institution, I always had a variety of plants, &c., from the conservatory in my sitting-room, and among others five or six specimens of *Primula obovata* in pots. Before long I began to suffer from an eruption

of the skin all over my hands and fingers, and to all appearance I was undergoing a severe attack of eczema. I tried all possible remedies, treating it as eczema; but it became worse and worse, till one day a friend calling, I apologised for the dreadful state of my hands. She said: "No wonder, with all these plants in the room." I said: "What do you mean?" She replied: "Why, of course, I mean all those *Primulas*, and if I touched one I should be covered with a rash before I got home." She continued: "Remove all those plants to-night, and in three days you will be well." I most reluctantly parted with my beautiful *Primulas*, and in an incredibly short time the irritation died away, and in a few days the misery I had endured was at an end, and my hands perfectly well. Now, it is very remarkable that I rarely touched those plants, unless by chance in watering them, so evidently to some persons they must emit a poison in a way not easy to explain, and since this dire experience I have been afraid to enjoy the companionship of even one of these lovely, innocent-looking *Primulas*, which are, too, so suitable for and easy to keep in bloom. Our gardener told me he also knew a man who could not keep them, as he invariably "had a rash" when working among them.—G. G. O.

OUTDOOR PLANTS.

IMPROVEMENT OF SOILS.

RECENTLY I gave a few notes upon liquid-manures, and I now follow with a few practical hints upon the above. The average amateur does not possess a favourable garden soil, and until this remedied satisfactory results are not easily secured. It is not that the soil was naturally bad in the first instance, but it has been almost ruined by the builder. The clayey or gravelly subsoil, broken bricks, old mortar and cement, and other builders' rubbish unnecessary to particularise, makes a soil that would fully account for the many failures unless a little commonsense be devoted to its improvement. If what was once the surface-soil is naturally of a light character, the clayey portions may be left; but if the contrary should be the case, get rid of the clay as much as possible. Collect the bricks, stones, clinkers, &c., and empty them upon paths, or else as a drain. They may be placed in a heap in some damp corner, when with a few larger pieces, and a little suitable soil, a very slow collection of hardy Ferns may be grown. Presuming we have arrived so far, the next things are trenching and manures. Upon a soil of medium nature any manure will do; but if it is stiff, then use soot, a little lime, road-grit, leaf-mould, and others of a light and opening character, reversing this for a light and porous soil. Thoroughly mix the whole while trenching, and use a little judgment whether the whole, or only a portion of the lower soil, be brought to the top. Bear in mind that a stiff soil of a fairly rich character does not need much manure, and will soon get overrich in humus if so treated without being heavily cropped; whereas a gravelly soil will take double the amount of feeding with excellent results.

P. U.

A Carnation note.—I was told the other day that Carnations were the coming flower, meaning that they would be the most popular flower grown. While not thinking they will stand before Roses, I certainly think they are one of the most dangerous rivals the Queen of flowers possesses. Many readers have doubtless got a few plants of the tree or perpetual-flowering Carnations. These are generally grown for their grand winter-blooming qualities that they form a great feature among winter flowers, and should be in every collection of amateurs' plants. It will be necessary to keep a sharp look-out for maggots, aphids, and thump at the collar. Watering is of special importance in cultivating the Carnation, more particularly at this dull season. It is too late to strike any cuttings this year as they should be done in September or October. But if a special favourite is wanted in greater number, a few cuttings may be taken off early in February. Some pull them out in preference to cutting them off of the plant. There is not much choice. Either way they need the base of the cutting slit for a quarter to half of an inch upwards, as they root more freely when so treated. A very sandy soil should be used, and

pressed firmly around the cutting. Place them under a bell-glass, and in a temperature of 60 degs., if a very gentle bottom-heat can be given so much the better. Another good plan is to plant out the stock plants and layer the shoots at their base. These make the strongest plants, and may be lifted in August, potted, and stood in a cool frame. The greatest mistakes amateurs make with winter-flowering Carnations are too much heat, too much water, and not sufficient ventilation during open weather.—P. U.

CORN POPPY (PAPAVER RHÆAS).

In reply to inquiries, the Carnation, Picotee, and Ranunculus Poppies are double forms of the common red or Corn Poppy (see illustration), possessing almost every colour except blue and

Flowers of the Corn Poppy.

yellow, some being self-coloured, while others are beautifully variegated. They are also known as French and German Poppies. The very beautiful Shirley Poppies originated in carefully-made selections from the Corn Poppy. Being hardy annuals, the seed can be sown where they are to bloom. Sow thinly, and thin out the plants to 6 inches or 8 inches apart. They are also excellent flowers for a semi-wild place, as at a distance their effect is striking and brilliant in the extreme. G.

HOLLYHOCKS AND DELPHINIUMS.

In a mixed shrubbery, or on the skirts of a lawn, many grand herbaceous perennials can be grown, but those most suitable for small borders and gardens are not of sufficient size for creating the best effect where more space is available. Short-growing subjects have a somewhat funny appearance when placed in front of, or among a large range of shrubs. Fortunately there is a vast number of herbaceous perennials, and it is not difficult to select suitable subjects for almost any position. The two grand flowers at the head of this note are probably the best and most showy we could choose, while they are certainly among the easiest to grow and propagate. We also get an immense range of colour in them, the Hollyhock giving us white, cream, pink, yellow, red, maroon, crimson, and a deep slaty purple, while in the Delphinium we have blue in all its various shades. Both produce noble spikes of bloom, and are quite indispensable where large gardens exist. Around the borders of a well-kept public park a grand effect was produced during the past summer by using these freely. Seedling Hollyhocks of a good strain give considerable variety in colour, and are more vigorous and less subject to disease than struck plants from named varieties. Delphiniums may be parted almost *ad lib.*, and continue in bloom from the end of May until a sharp frost cuts them down. In order to get a good succession of spikes, it is necessary to cut these down as they go out of flower, otherwise the plant devotes its energies to maturing seeds. But if removal as soon as their beauty is past, other spikes push from the crown, and a grand effect is maintained until winter is well with us. My own Delphiniums were carrying good spikes of bloom up to November 7th, and even after that frost of several degrees (7 to 9) they have been quite showy. A spike of Hollyhock will continue in bloom for the best part of

three months, so that these two flowers afford a grand show over a long period. Both of them will grow in almost any soil; but if a deep, rich loam can be provided the results are much more satisfactory. The Hollyhock in particular is a deeply-rooted plant, and derives most benefit when the manure is placed some 14 feet to 2 feet deep. When growing near to established shrubs or trees, especially during a dry season like the past, the labour of watering will be amply repaid. Thorough soakings should be given, or none at all, one good watering being far more effectual than many of a half-and-half character. P. U.

4962.—**Planting Gladioli.**—I presume you mean autumn-flowering kinds (hybrids of *Gandavensis*). The best time to plant these is from the beginning to the middle of March. They do well in any ordinary garden, and may be planted 1 foot apart in rows, or in clumps of three to five bulbs in each between Roses, Dahlias, or other plants. They make a fine display in autumn, and are most useful as cut flowers, the spikes lasting a long time in water. They are now extensively used for church and other decorations, and to show how suitable they are for this purpose, I may mention that the Messrs. Kelway, of Langport (who grow thirty acres), send some thousands of spikes weekly to all parts of the country, the majority being used for decorations at harvest festivals, &c. There are many varieties, embracing almost every shade of colour now in cultivation. *Brenchleyensis*, bright scarlet, is one of the best to plant extensively for garden decoration. If exhibition spikes are required, special attention as to cultivation, &c., is necessary, and a few hints on this subject may prove useful. Choose a good open situation, and prepare the land at once by trenching it to the depth of 2 feet, mixing a liberal quantity of old hot-bed or well rotten cow-manure with the soil. In March plant the bulbs 3 inches deep and 1 foot apart. When the plants are about 1 foot high, spread a good layer of half-rotten manure over the ground, which will promote strong, vigorous growth, and put a neat stake to each, and tie as they advance in growth, which will prevent the spikes being damaged by the wind. As soon as the flower-buds appear a dose of manure-water applied to each plant about once a week will work wonders in developing the size and colour of the blooms. I shall be pleased to give a list of the best show varieties at some future time. —E. J. P.

5020.—**Plants for carpet bedding.**—*Herniaria glabra* is one of the best of low-growing plants for this purpose. *Sedum glaucum*, *S. Lydium*, and *S. acre elegans* are also desirable subjects to plant, and so are the different varieties of Saxifrage, like *Camposi*, *ceratophylla*, *hymnoides*, and *unscoides*. All these are not only pleasing in their growth, but when in flower they lend additional attraction to the border. *Veronica prostrata* (with deep-blue flowers), *V. incana* (silvery foliage), and *V. repens*. This latter does not grow more than 2 inches high, and is smothered with tiny white blossoms in April and May. *Empetrum radicans variegata* is really a hardy shrub, but it is of a trailing habit, that it is well adapted for such a purpose as the one now under consideration. Its silvery leaves are attractive during the dull days of winter. *Armeria rubra* and other kinds of Thrift may be employed easily in the same way, as all are low and dense-growing subjects. Where Gentians succeed, nothing could be better than masses of either *canalis* or *verna*; their lovely deep-blue flowers are always attractive.—S. P.

Judging from your query, I suppose the ordinary carpet holders are not intended, as "London Pride" would scarcely come under this definition. There is a wide selection of things, and you may employ some annuals as *Mignonette*, which is delightful with Roses. The Blue Apennine Windflower is very charming at the foot of trees, *Arabis albidia* is a sheet of white early in the spring, and would do well for the front of the border, also *Aubrietias* in variety, the dwarfed *Campanulas*, as the white *C. puncta* and *C. fragilis*, Pinks, Carnations, if these are not too tall, *Gypsophila paniculata*, Creeping Jenny, and the yellow-leaved variety, *Mimulus* in variety, if the position is

not too dry and hot, dwarf Phloxes, masses of flower of varied colour according to the variety, but all are good, except those of a purplish-magenta tone, the white-flowered *Pyrethrum Tchihatchowi*, Saxifrages in great variety, particularly the Mossy Saxifrage (*S. hypnoides*), *Sedums* in variety (*S. Ewersi*, *S. Sieboldi*), and *Stonecrops*, *Sempervivums*, *Thymus lanuginosus*, *Veronica saxatilis*, Tufted *Panicum*, *Alyssum saxatile*, which has a brilliant mass of yellow flowers in spring, the Thrifts (*Armeria vulgaris*, and the taller growing *A. cephalotes*), *Ballicolium verum*, which is very pretty used as a carpet plant to beds of deciduous shrubs, the flowers being produced in spring, *Crocuses*, *Winter Aconite*, the variegated *Dactylis*, *Krythrionium*, better known as Dog's-tooth Violets, dwarf Iris, and Scillas. You may get many pleasing contrasts of colour with dwarf plants, the golden-leaved *Creeping Jenny* being very charming when covering the ground, and such things as *Fuchsias* used to break the surface.—C. T.

Mossy lawns.—These are almost always caused by poorness of soil or wet, either from soakage or because the ground is naturally of a close and retentive nature. Unless this be remedied there is no permanent cure for the mossy patches so disfiguring to a lawn. The drainage must be attended to, but as no Moss will grow upon good soil, the judicious use of manure is very important. Farmyard manures are apt to produce too strong a growth, even when a good selection of lawn Grass-seed has been used. I prefer soot and wood-ashes, also the sweepings of roads. Before applying these, rake off as much of the Moss as you can. In the early spring give the lawn a good dredging with rough boughs, and sow a little seed on the bare and thin places. This will usually ensure a fine soft Grass, and if a little of the small white Dutch Clover be added a great improvement will be seen.—P. U.

ORNITHOGALUM NUTANS.

In reply to "J. G.," "H. R.," and others, this is a very popular species, and one of the most easily-managed of all the *Ornithogalums*. In

Drooping Star of Bethlehem (*O. nutans*).

borders amongst other bulbs it may easily become a nuisance on account of the freedom with which its innumerable bulbils are forced. In a semi-wild or uncultivated spot it is a capital subject for groundwork; it requires no attention whatever, and flowers freely all through April and May. The blossoms (see illustration) are borne in racemes, drooping, green on the outside, whitish-green inside, peculiarly attractive. *O. Boucheanum* is a more form of the above with larger flowers. *O. nutans* is a native of Southern Europe. G.

5020.—**A bed of Lily of the Valley, &c.**—The Lily of the Valley may be grown well in a half-shady spot which is moist. A border overrun with roots would not do at all, as the plants would soon be starved in such a place. I should say that in the position mentioned the plants would thrive to perfection, and in a south aspect one gets earlier flowers. The great thing is to have a well-manured loamy soil, and kept moist during the growing season. It is really too late to plant now, the early autumn being the best time for the work—that is, when the leafage has died down. Too often beds are left until they become so crowded up with plants that they get weakly, and the flowers few and far between. Carnations should have a good loamy soil, with which is mixed plenty of well-rotted manure. Kibarbonate compounds are not in the least necessary. It is too late to plant now, and the layers must be kept over the winter in pots. Put them out in the month of March. As regards planting new beds, be careful to see that the soil is not infested with wireworm. This pest is very destructive. During the following summer after planting keep the Carnations well supplied with water.—C. T.

— This is a very simple matter, and that is necessary being to dig the ground over well and add a fair dressing of either good leaf-mould or well-decayed manure. The plants enjoy some shelter and a little shade, but not too heavy. Beds for Carnations should also be well dug, if possible to the depth of two spades, working in a moderate quantity of old flaky hot-bed manure and some burnt earth; old mortar-rubbish and a little snot are also very beneficial. If the soil is naturally heavy and damp put plenty of broken bricks, rough ballast, or the like in the bottom of the trench, and, if necessary, a drain also, and in this case plenty of sand may also be added with advantage. In other words, good sandy loam and leaf-mould, with some burnt material and mortar-rubbish, suits these plants as well as or better than anything else, either in the open ground or in pots. Always make the soil firm.—B. C. R.

4945.—**A garden in Surrey.**—Having had to deal with a similar soil to this one, I give my experience. Ten years ago I took charge of this place, which at that time was mostly Common or Heath land, the soil being a dirty white sand to the depth of from 1 foot to 2 feet, then black or yellow rock, commonly called iron-rust about here, under which is a very good yellow subsoil (sometimes gravel) to the depth of from 6 feet to 10 feet, this yellow soil reaching to the depth of 30 feet, or more, according to elevation of hills; then we reach a running sand containing water. I will take first the surface-sand. Nothing will grow in it but Scotch Fir, Birch, and Heather, it being so very poor; it will hold no moisture, and in hot, sunny weather it gets so hot that I have seen plants burnt black, and as to water, I might use the old proverb of pouring it on a duck's back. Next I take the iron-rust. It is generally about 1 foot thick, and just like a bed of concrete, and from 1 foot to 4 feet under the surface, and no moisture can either rise or percolate through it in any way, nor yet the roots of trees, it being so hard that it requires a pick to break it, especially if mixed with gravel, or overlaid gravel. Occasionally we find some that can be broken with a fork when overlaid the yellow subsoil, but that is not often. Now I come to the yellow sandy subsoil which is very good when brought to the top, and will grow anything; but I must here say that the rust must be thoroughly broken, and if exposed to the weather will fall almost like lime, and when mixed with the yellow subsoil forms very good soil for a garden, and when cultivated in the usual way will grow very good fruit, flowers, and vegetables, but must have plenty of good manure. I may say I have about thirty acres, some trenched from 2 feet to 6 feet deep, and ploughed from 2 feet to 3 feet, and with plenty of manure I have had very good crops of all kinds, and Conifers and flowering shrubs grow amazingly, so that if "M. D." wishes to have a good garden I should advise him to have his ground trenched two good spits deep below the rust; but he must see that the rust is thoroughly broken up, as I am sorry to say I have had a lot of trouble through some of the work being shirked, especially where the rust was very hard, and it not well broken. I don't go

back to its natural state. I should advise "M. D." to take up his fruit-trees and replant them in trenched ground. The border should be trenched the same way and well manured. I have some hundreds of yards of borders done in the same way, which are giving every satisfaction, some from 2 yards to 10 yards wide, planted with herbaceous plants of almost all kinds.—Fox-Hills.

NOTES ON BEGONIAS.

These charming flowers have been on the whole somewhat disappointing during the past season, both out-of-doors and, to some extent, inside also. The extreme and continued drought and heat were, in fact, too much for the plants, which dislike extremes of all kinds, and never thrive so well as in a temperate climate, and under conditions moderate in all respects. If there is one thing of which they can scarcely have too much—at any rate, when growing in the open ground—it is moisture. I shall never forget how they thrive, even in my stiff, clayey soil, during the mild, but wet and stormy, autumn of 1891. I have never seen them grow and bloom as they did then before or since. No amount of artificial venting appears to have the same effect upon the growth as the natural rain, but unless the plants, and seedlings of the same year in particular, are frequently and copiously watered for some time after being planted out, and until thoroughly established, they sustain a severe check if the weather proves dry, and frequently fail altogether, or refuse to make satisfactory progress afterwards. But even with the greatest care seedlings planted out in June made very little progress until the dull and showery weather we had in July set in. This gave them a start, though some of my beds were not planted till about this time, the seedlings not having grown quite so fast as usual, owing to the heat and drought; but these did, in the end, nearly or quite as well as those planted earlier. The intense heat in August again proved very trying to the plants, and on one or two of the hottest days (the 17th and 18th, I think) plants in beds fully exposed to the sun were literally scorched by the burning rays of the sun, not only the blooms, but many of the leaves being shrivelled. However, I took the precaution of shading all the best beds with thin canvas, and so saved most of them. The rains that set in about the middle of September again refreshed and helped the plants considerably, but the weather at the time was too cold, and on the 8th of the month a sudden and very heavy hailstorm cut the plants about half, and chilled them as well, as we had literally to scrape the hailstones from round and between the plants in pain. About this time, too, we had several frosts sharp enough to touch the blooms and tops of the plants where unprotected, but by covering the beds roughly with a light framework of laths and tiling, &c., more than a very slight damage was avoided. This is a point that seems to call for more particular notice. It very frequently occurs that some time in the early part of September we get one or more nights sufficiently frosty to injure such tender subjects as these, while the weather afterwards, often for several weeks, is so mild that, if protected in some way during the critical period, they then remain in beauty for some time longer. Such was the case here in Sussex, at least, this year, and by simply protecting the beds the plants were kept on blooming beautifully until nearly the end of October, the frost that finally settled them occurring on the night of the 30th of that month. My Begonias, indeed, were far finer and gayer during October than at any other period of the year, one bed in particular, filled with plants raised from quite small tubers no larger than Peas, kept over from the previous season, being quite a sight, and many of the blossoms 5 inches to 6 inches in diameter.

UNDER GLASS, too, the heat was altogether too much for these Begonias. Here, on the Wealden clays, the heat is as intense in the summer as the cold is in winter, and the thermometer on several occasions rose well above 90 degs. in the shade. This so distressed the indoor plants that at last I turned most of them outside, standing them on slabs in the shade of trees, where they did not require nearly so much water, and gained strength considerably. Under such circumstances the only way to keep these plants in health under glass is to shade them for

heavily (from actual sun only), and admit air as freely as possible by night as well as by day, few would credit how greatly night air strengthens these and nearly all plants in very hot weather. Water must be abundantly supplied, and the plants be syringed overhead at least twice daily. Just after the hottest week in August I was going through a nursery where large quantities of Begonias are grown, and found scarcely one in a hundred carrying any bloom to speak of, both indoors and outside, but in the houses they had evidently been insufficiently shaded and apparently overwatered as well. At least at one of the metropolitan exhibitions held in August there was also not a single Begonia staged, a fact which tells its own tale. The system of planting out the Tuberos Begonias under glass is beginning to be adopted by some growers. Years ago I saw them thus put out in low pits or frames, and have indeed grown them in this way myself, but quite recently I saw several hundreds planted out in the side-beds of the ordinary span-roofed houses at Swanley, and the plants were doing well. In this way they grow faster and stronger than in pots, and do not require half the care and labour in watering. In the case of soil, there is nothing better, if to equal, good friable or fibrous loam, whether the plants are grown in pots or planted out. Mix it with half, or a third, the quantity of good flaky leaf-mould (not too much decayed), and a good dash of slimp or course sand, and they can scarcely fail to thrive, and will make shorter and stockier plants than those grown in peat or any material of a lighter description, while the flowers will be large and of great substance. The choice new erect-flowered doubles, with a dwarf habit, do not grow as freely as the older and commoner kinds, and these may have a third or so of peat added also, especially if raised from cuttings instead of seed, but for the ordinary run of seedlings, both single and double, I find them do better in a sound loamy compost than any other, and at any rate, when putting the plants into the flowering sizes, the soil should be made quite firm. For drainage I use either Irish cod-cinders or nodules of ballast (burnt clay) with excellent results. Those who can obtain spent Hops I can strongly advise to try this material for Begonias, whether planted out or in pots. Let them lie for two or three months, turning the heap over occasionally to sweeten them, and to two parts of loam add one of the Hops (well pressed down), for pot plants, or dig them freely into the ground before planting. They also form a splendid mulching material. Lastly, the erect-flowered kinds, both single and double, should be cultivated almost to the exclusion of those with drooping blossoms, which, except for baskets, &c., are poor, ineffective things compared with the others. I generally save my own seed, taking it from erect-flowered plants only, and could not help noticing that in the bed of last year's seedlings referred to scarcely a pendulous dower could be found—all stood up well on stout stalks, and looked you straight in the face as if not at all ashamed of themselves. The same remarks apply with equal force to the double-flowered kinds—one that stands well up and looks skywards is worth half-a-dozen drooping blossoms to my mind, and I wonder that more importance is not attached to this valuable trait. Of course the huge deep, many-petalled or many-centred double flowers cannot possibly stand upright—no stalk could carry them thus—but we are gradually getting a race of small, single-centred flowers with a few broad and well-rounded petals only, and with the proper habit of plant these can be held as erect as the singles, while they possess the important advantage of lasting very much longer, and blooming almost as continuously. B. C. R.

5010.—**Treatment of Petunias.**—Young cuttings are much the best, and to obtain young shoots the plants must be started back now or earlier.—E. H.

Injury to Beech-trees.—You may possibly remember that I wrote to you about widespread injury to Beech-trees in this neighbourhood. I found it was due to the larvae of a small beetle, which I have watched from its early stages to the perfect insect. I have learned that its name is *Orthocentrus* sp., a weevil. It has done much mischief in the forests of the country, the Beeches soon losing their beauty and remaining so for the rest of the year.—R. L.

THE KITCHEN GARDEN.

NOTES ON TURNIPS.

There are now several more or less distinct varieties of Turnips in the different sections. Take the Snowball (see Fig. 1) type, of which we have numbers of supposed good selections. Quality in many Turnips is more a matter of culture than anything else, the nature of the soil making all the difference. Of course age in

Fig. 1.—Turnip "Snowball."

the roots often makes a difference, but not to such an extent as soil. The Turnip delights in what we may term a calcareous soil, but this must not be poor, or the roots will fail to make much headway. The best quality Turnips I ever had were in a garden near the sea. The soil was rather deep and on the limestone formation. Where Turnips do not succeed, a dressing of kainit should be given, a little salt also being applied, say half an ounce to the square yard. It was after noting what beneficial effects the sea spray had upon the Turnip crop that I was led to apply the salt. Burnt soil is also admirably adapted for the Turnip crop, it being a usual thing for farmers to "soil-burn" for this crop, small fires being kept going at intervals over the piece intended for the crop, the ashes being afterwards distributed over the land. Old garden soils are often unsuitable for the growth of Turnips, and in these cases a dressing of fresh slaked lime would prove of marked benefit, and also help to destroy the disease termed smut, or finger-and-too. These soils are generally overrich in nitrogenous matter, and deficient in those mineral elements needed for the crop. Commencing with the

EARLY VARIETIES. I find the Early Milan is the best. This variety I consider the most useful of what are known as the strap-leaved. It is undoubtedly the most useful for early sowing in the open air, and also for forcing under glass. The Red American Stone Strap-leaf (Fig. 2) forms a very good succession. The Early Munich is not worth growing. Certainly it was useful, as it was introduced before the Early Milan, and was more to be depended upon than the selections of early strap-leaved that used to be recommended for this purpose. Two or three years since I got together what supposed early varieties I could, both the English and the Paris market forms, but I found for open-air culture in this country they could be very well dispensed with in favour of the Early Milan. If desired after this, the Early Red American Stone may be sown, but I prefer a good selection of the Mousetail, the selections of Snowball coming under this head. So much are the Snowball types liked by many people, that no other is grown. If I was bound down to three varieties, it would be the Snowball, Early Milan, and Orange Jelly, selections of the last now being known as the Golden Ball. This latter is a very hardy Turnip, keeping well on to the early spring in the open ground, and coming into use after the Snowballs are all used up. Some people profess to have a liking for yellow-fleshed Turnips, but I do not think they will ever become popular. In the north of England and Scotland they appear to have a greater hold upon the public, but for table use their colour is against them, however good they may be for flavouring. A good early yellow-fleshed variety will be found in Petrowski. Veitch's Red Globe is a well-known red-topped Turnip, good alike for summer and most excellent for winter use. ~~What is termed the White-stone section. This is~~

flatter in form than the Mousetails and with a coarser tap-root. I do not care for it for summer use, but it is good for winter. It is largely grown in Essex for the supply of the London markets, and is a good form for sowing late for the supply of Turnip-tops in the early spring. The green-top Stone is also liked by some people for winter, but it is more favoured by cottagers. Last, but not least, is Chirk Castle Black-stone (Fig. 3). This is certainly not a very inviting-looking variety, but has a remarkably white flesh and is very hardy, being, in fact, the hardiest of all, although I must say that I have found Orange Jelly or Golden Ball equally hardy. When not too large, any amount of frost which we are likely to experience never harms them. As a precaution, however, a little soil drawn over them removes all risk, as the quality is better when left in the ground. A.

KITCHEN GARDEN WORK.

AFTER one of the longest summers on record, we have now fairly settled down to our winter's work, and at the commencement a good many crops need special care, for the exceptional heat of summer, followed by mild autumnal days, caused a luxuriant growth in all kinds of green vegetables, and in place of a scarcity there is absolutely an overabundance of green crops, and, above all, they are too gross to withstand very severe weather, if it should set in suddenly. The following crops need attention at once—

ASPARAGUS-BEDS should have the old tops cut off, the surface soil stirred, and lightly pricked up with a fork, and a dressing of seaweed or manure spread on the surface and left until spring.

BETROOTS, if not already done, should be lifted very carefully and placed in a cool shed out of the reach of frost.

BROCCOLI, when overluxuriant, will be greatly benefited by digging out the soil on the north side, then press the plant down, and pack the soil from the next plant right over the stem, as this is the most vulnerable part.

CABBAGES that were planted out early have grown very rapidly, and should severe weather follow may suffer considerably. If good plants are available, a successional sowing should be put out, as they will come very acceptable if the first lot runs prematurely to seed or suffer from frost.

CARROTS.—If any seed was sown at mid-summer, the roots will now be in excellent condition for use, and they are very much more tender than those sown early in spring, and if they can be kept in the soil by means of litter

Fig. 2.—Turnip "Red American Stone Strap-leaf."

shaken over them when severe frost sets in, they will be found a very much nicer vegetable than those stored in sand.

CALIFLOWERS of the Autumn Giant and Early London kinds planted after Early Potatoes where cleared off are now in splendid condition, and require care in protecting from sudden frost; break the leaves down closely over the heads, and when quite fit to cut lift with balls of earth, and place in cold frames or sheds until required for use.

CELERY.—Late crops should be fully earthed

up, and those fit for use should have some litter put over the tops, if severe frost sets in, not only as a protection, but to enable the lifting to be done in spells of sharp frost.

LETTUCE, if fit for use, must have protection of some kind from severe frost, or lifted and replanted in frames. A good supply of plants should be lifted and replanted under hand-glasses or in frames, as they suffer severely when overluxuriant as they are at present.

PARSLEY, which is in daily demand, should

Fig. 3.—Turnip "Chirk Castle Black-stone."

have some thatched hurdles prepared for its protection, so that if snow falls heavily it may be got at readily. A few roots in boxes are very useful.

TURNIPS of white kinds are now abundant. A good quantity should be lifted and laid in trenches, covering the roots right over with soil, leaving the tops out, so that they can be readily got at when needed.

SEAKALE AND RHUBARB-ROOTS lifted now and planted in any warm, dark place will yield fine blanched dishes in January, when anything in the way of forced vegetables is much appreciated.

SMALL SALADS, such as Mustard and Cress, should be sown in boxes and set in the greenhouse. It is always acceptable, and remains fit for use a long time at this period of the year.

J. GROOM, Gosport.

Winter Herbs.—Mint, Tarragon, and Parsley are much better in many cases when they can be used green or unblanch, and as it is a very simple matter to have them in this state during the winter months I supply a few hints upon the method to be pursued. If you have a heated pit or frame, or even a cold one in a nice sheltered position, a few roots of Mint and Tarragon may be lifted and inserted. I prefer a shallow box of light soil, as they grow more freely, and can be easily lifted out when spring produces plenty of the same out-of-doors. Or they may be stood on some out-of-the-way shelf in the greenhouse, and, provided they are not too freely supplied with water until growth commences, a number of very acceptable pickings may be obtained during winter months. Parsley, Sage, and Thyme are better for a little protection during severe weather.—F. U.

5008.—Celery for show.—Sow the seeds in heat in March. Prick off in rich soil in frame 4 inches apart as soon as large enough. A layer of rotten manure 3 inches thick is usually placed in the bottom, and then 3 inches of rich soil on the top of the manure pressed down with a board. The plants must always be liberally supplied with water. A little weak liquid-manure may be given when the plants are growing freely to get the plants as strong and robust as possible. From the first everything must be done to have the plants as strong as possible. A check from drought or too much heat would be ruinous. As soon as the plants are large enough to plant in the trenches get them out at once. The manure must be rich, but not fresh or rank, and it should be well blended with the soil in the bottom of the trench. I have seen very good results when the

manure has been worked into compost with old rotten turf and some decayed vegetable matter; the roots take to it better. Plant in single rows from 10 inches to 12 inches apart. As the plants progress all the small sucker-like growths which sometimes form on the sides of the plants should be removed, and the plants must never be permitted to get dry. When the growth is well advanced give liquid manure twice a week, not in dribbles, but a thorough soak. About six weeks before the Celery is required wrap some paper round the bottom, say about 5 inches or 6 inches up, rather loosely. This will hold the plants up a little and commence the blanching. In another fortnight or so add more paper higher up, drawing the leaves a little closer in, but still leave room enough for growth. If several thicknesses of paper are used, the Celery will not require earthing up. The heads will turn out white and free from bluish. As regards varieties, good culture and regular attention in watering is more important than any particular variety. Every good seed house supplies good Celery with which prizes may be won if well grown. Sutton's Sultan Prize Pink, Carter's Incomparable Crimson, Thurston's Incomparable White are all good. A good strain of the Manchester Prize and Grove's White are also suitable.—E. H.

5025.—**Growing early Rhubarb.**—Cover the rhubarb with tubs or pots, and surround them with leaves enough to ferment, and the warmth from the fermenting leaves will start the Rhubarb into early growth.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of GARDENING, 37, Southwark Street, London, E. Letters in business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent in press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers.—Which, with the exception of such as cannot be classified, will be found in their different departments should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, rules, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5051.—**Laurels.**—Will someone please tell me if I can plant back the tops of Laurels now?—CONSTANT READER.

5052.—**Pilea alba latifolia.**—Will someone kindly give me a few hints as to the treatment of this plant?—L. L.

5053.—**Replanting Seakale.**—Is this the best time to replant Seakale, and how should it be done? Please give particulars of soil to be used, &c.—M. A. H.

5054.—**Plumbago capsensis.**—If I put a two-year-old plant of Plumbago capsensis in a pot two sizes larger in spring will it stop it from flowering?—P. M. B.

5055.—**Dracaena in a room.**—Do Dracaenas (kept in a room) require much water at this time of the year? Any hints on the subject will be acceptable.—M. H. F.

5056.—**Names of Chrysanthemums.**—I shall be obliged if anyone will inform me if "Source d'Or" and "Bonne d'Or" are one and the same Chrysanthemum?—L. M. T.

5057.—**Best Carnations.**—I shall be greatly obliged if someone will give me a list of the newest and best Carnations with colours? I want to get a good collection.—C. N. B.

5058.—**Early Potatoes and Brussels Sprouts.**—Will someone kindly inform me the proper distance to plant early Potatoes apart in the rows, so that Brussels sprouts may go between?—S. W. P.

5059.—**Pruning a Wistaria.**—Will someone please tell me if this is the time to prune a Wistaria sinensis on a dwelling-house? Should all the long young shoots be cut back close or not?—A. CONSTANT READER.

5060.—**Treatment of Darlingtonia californica.**—I wish to grow this Darlingtonia in a cold frame. Will someone kindly give me full instructions for doing so? Locality, south-coast.—P. L. H. F.

5061.—**Pampas Grass.**—I have a large Pampas Grass. I am told to cut it down close to the ground. Hitherto I have partly done this every year. Will someone kindly tell me which is right?—A. CONSTANT READER.

5062.—**Propagating greenhouse plants.**—Will someone kindly say what is the proper time of year for taking cuttings of the following: Antirrhinum, Fuchsia, Zonal and large-flowered Pelargoniums?—R. B. S.

5063.—**Aspidistra.**—I find the leaves of my Aspidistra variegata are always splitting and turning yellow. What is the cause, and what should I do to prevent it? Any information on the subject will be acceptable.—M. H. F.

5034.—**Tea Roses for button-holes.**—I should be pleased if someone would kindly name twelve of the best thorn button-hole Tea Roses for a cold house? Aspect, west; locality, smoky, Bolton, Lancashire.—AMATEUR ROSARIAN.

5035.—**Baking for button-hole Roses.**—Will some reader of GARDENING inform me of a good plant as a backing for button-hole Roses, which I would grow in a cold-house? I have tried *Asilinum concinnum*, but failed.—AMATEUR ROSARIAN.

5036.—**A viney border.**—Will someone kindly advise me as to a long border which is in my viney? The Vines are planted outside. Would it do any harm to the Vines if I were to plant Tomatoes, or millise it for any other purpose?—G. F.

5037.—**Pruning dwarf Roses, &c.**—Would "J. C. C." or "P. C." oblige by telling me when is the best time to prune dwarf Roses in the ground, and also Tea Roses in an unheated greenhouse? Locality, Newton Abbott, Devon.—D. C.

5038.—**Rose-hips.**—I have some Rose-hips (wild) sent me to sow for stocks. Should I sow now or wait till spring? I have also some Hadford Colville alba and The Bride. I am anxious to increase. Which is my best way to proceed?—M. A. TURNER.

5039.—**Window plants in winter in London.**—Will someone kindly state how best to keep window plants in health in London during the winter, and the best plants to obtain for such a purpose?—Mrs. E. E. H., *Somme-square, Chelsea, S.W.*

5040.—**Chrysanthemum cuttings.**—I have some strong, well-grown shoots from the ground in my Chrysanthemum-pots quite long enough for cuttings. Should I do wisely to make cuttings now or wait two months?—E. FISHER, *Chauntry, Norwich.*

5041.—**Using a lawn-mower on tennis-courts.**—Will anyone have the goodness to tell how frequently the lawn-mower ought to be used for tennis-courts, &c., and the roller also, and how long their use should be continued after the summer?—R. L. A.

5042.—**Diebudding Chrysanthemum.**—In diebudding Chrysanthemum is it proper to remove the three lower roots, the centre one, or to leave those and take out the centre one, in order to get fine flowers? Can I get fairly large flowers on dwarf plants?—G. R.

5043.—**Rose Baroness Rothschild.**—I have a rooted cutting of Rose Baroness Rothschild about 6 inches in length. Can I grow it as a standard? I have rubbed off all the lower limbs, and there is a little shoot near the top with several buds. Can I train that into a "head"?—C. B.

5044.—**Seeds of Clematis Jackmani, &c.**—Would "J. C. C." or "B. C. R." or someone else kindly say how I am to sow the above seeds now ripe? Also, the seeds of the Star, or sweet-scented Clematis, that flowers in autumn? Also, Apple and Pear seeds?—S. B. S., *Dunelm.*

5045.—**Ornium ornatum.**—Will someone kindly inform me how this lily should be treated during the winter? I have a fine bulb which I imported in the spring. It has grown very slowly, and has not bloomed. Ought I to keep it green, or let it dry and rest in the spring?—C. R. A.

5046.—**An Indian vegetable.**—Will someone kindly tell me the correct name of a vegetable known in India as "Lady's Finger"? Also, how to grow it in this country? The seed is green, and the size of a small Pea. I shall be pleased to send anyone a few seeds to try. Address with editor.—R. N.

5047.—**Pruning a pot Rose, &c.**—I have in a cold greenhouse a pot Rose, and do not know how to prune it, and I see mentioned in GARDENING of November 24th that pot Roses ought to be pruned. I have also got among the roots two *Marshall Niel* Rose in pots. Ought they also to be pruned now?—CONSTANT READER.

5048.—**Chrysanthemum suckers.**—Would not the rooted suckers that come up at the bottom of Chrysanthemums be quite as useful to make good plants next year if they were taken up and planted with as much soil as possible, instead of going through the troublesome business of taking cuttings from them?—C. P.

5049.—**Trees, &c., for a Derbyshire garden.**—I am about to remove to a new house in Derbyshire, which is 1,000 feet above the sea, and should be glad to know what trees, shrubs, and plants would be likely to do well, and make the garden look bright, as I do not intend to bed out much? The winters are long.—AN AMATEUR.

5050.—**Treatment of a Schubertia.**—Will anyone kindly tell me how to treat a *Schubertia* now? It is not rest all winter, and in a dry state. Should I lose all its leaves, and what is the best soil to grow it in? There is only one pip opens on every truss at a time. Is this normal, or should the truss all open before gathering?—L. C.

5051.—**Unhealthy Poinsettias.**—Will anyone tell me what is the matter with my Poinsettias? The leaves are continually shriveling up, and they do not grow in the least. They are in a house with *Coleus* and *Irvingia*, which are doing very well. Ought they to be syringed daily now, as I understand they should be in summer?—AN AMATEUR.

5052.—**Making a window-box, &c.**—I am anxious to have a window-box made. What depth should it be, and ought there to be any holes in the bottom for drainage? I should be much obliged for any hints as to the soil to use, and also the best plants to make it look gay from April to September? The window has a west aspect.—FOX.

5053.—**Rose in a greenhouse.**—I have a Rose (*Reine Marie Henriette*) which has been especially trained for the roof of my greenhouse, having a stem of 10 feet or 12 feet long with small 1-inch side-shoots, which I have repotted in about a 6-inch pot. Will this require any more than the ends of the main stem and shoots removing in spring?—P. M. B.

5054.—**Pot-Vines.**—I have three pot-Vines raised from eyes put in last January. They have each a rod of about 3 feet long. I want to fruit them next year. Should these rods be removed, or do you want length should they be cut back to? A few hints as to obtain a few good bunches would be very acceptable?—L. M. T.

5055.—**Name of a Lily.**—Will anyone kindly tell me the name of a beautiful Lily that I saw growing in gardens last summer at Conston? It was not unlike auratum, but had crimson where that has gold. I was told that in dull summers it did not flower in time to be safe from frost; but perhaps it would under glass. The plants were over 3 feet in height.—C. B.

5056.—**Fuchsia in a greenhouse.**—I have just purchased a *Fuchsia* in a 6-inch pot, the roots of which are just coming through the bottom of the pot. If anyone forming a plan in my greenhouse with some, and expense it stop it flowering if I put it in a pot one size larger in spring? It has about two shoots coming out of the main stem, which is hard wood, and 8 feet high?—P. M. B.

5057.—**"Paris green" and Pear-trees.**—How should "Paris green" be used on pyramid Pear-trees to protect them from the reappearance next spring of grubs and caterpillars, which, for the last few years, in spite of frequent hand-picking, have very much injured the crops of fruit. Should the "Paris green" be applied now, whilst the trees are in a dormant state, and if so, in what proportions?—E. B.

5058.—**A plague of sparrows.**—I am swarmed with Sparrows through keeping poultry, and being anxious to destroy them in accordance with the law, if anyone will anyone of your readers assist me in saying how I can trap or destroy them? I cannot shoot, being a joining a public road, and do not like to poison on account of a favourite cat.—J. T.

5059.—**A small greenhouse.**—I am about to erect a small conservatory at the back of my house, with an entrance to it from the drawing-room on the ground floor. The house faces the south, and so we get little or no sun in the back, where the conservatory will be. Will someone kindly inform me what plants would be most suitable, including a couple of creepers, and would any kind of Rose thrive? I suppose Ferns would do best of all, and may any that I wish to entail the expense as much as possible?—ALFREDAL.

5060.—**Rats in a garden.**—Will anyone kindly tell me how to get rid of rats in a garden? I am very much troubled with these pests, and now, when there is little food to be got, they burrow where the bulbs are, and either eat them or leave them on the top of the soil. I have settraps, but it does not seem to be of any use. The traps lately have been set with *Sinoflower*, which I heard rats are fond of, but I have not caught one. I ought to say our garden adjoins a wood, and the rats come from there.—M. L. WILLIAMS.

5061.—**Lilium auratum, &c.**—Are home-grown *Lilium auratum* bulbs to be preferred to imported ones? I am at a garden at a higher price, but I have always found that the bulbs decrease in size year by year. I intend buying some auratum and *sinuosum* for planting out-of-doors in borders. Is it safe to plant at once with the bulb in the more or less soft, fatty state as imported? I have generally potted them and kept them pretty dry for some time, and then cut them early in the spring, which I heard some of your correspondents say. I should like to know if this is a good plan, or if I should have cut them out-of-doors? A reply will be much obliged.—ALFREDAL.

5062.—**Pot-Roses.**—My pot-Roses, of such kinds as *Marshall Niel*, *Duke and Duchess of Edinburgh*, *The Belle*, *Etoile de Lyon*, *La France*, &c., in a cold land in winter, unless greenhouse, look more like March than November. They are in full leaf, all new foliage, and one or two have buds on. What shall I do with them? I have cut them, but not very much, since the fresh foliage came in. Some are small plants that would surely bear more cutting. The *Marshall Niel* does not look quite so well as the rest. I should like to train it, but it grows in a sort of straggling bush, and not with long shoots.—C. B.

5063.—**Seaweed as a manure in the vegetable garden.**—I should feel very much obliged by your able scouring me with a few hints on the above subject. My residence is on the sea-coast, so that I have every facility of obtaining the article in question. Hitherto I have never applied it, except as a thick covering in winter to the *Asparagus* and *Rhubarb*-beds; but my present gardener is desirous of using it as a dug-in manure to other crops, and I am anxious to know to what crops (if any) generally, or particularly, it would be suitable. If any member of my garden is a good sandy soil.—R. L. LEONARD SHARROTH.

5064.—**Soil for Roses, &c.**—Other readers to whom I have written "J. C. C." or "B. C. R." or other rosiarians to whom I am already much indebted, would advise me on the following point? My soil is about 25 feet deep, rather light, with gravelly bottom, so that it soon drives up, as garden runs north and south. In the western border I have twenty-three standards, eight of which are Tea and also a few dwarfs and H. P.'s (planted Jan. 4th). I used liquid manure (horse-droppings and soot) throughout the season, and at beginning of month with mulched with Moss, standards, rest *Bloomed* fairly well. Three weeks ago I planted some *Rij* dwarfs on seedling Brier round a beautiful plot, protected and mulched. Thinking to make the soil heavier last week I had two loads of stiff clay spread on the bed about 3 inches deep on the manure, and intend to let it lie there till next March, when I must go to bed in it with manure. Will they kindly tell me whether I am doing right, and if not, what I had better do?—ALFREDAL.

5065.—**Hardy Lily bed.**—I am laying out a new border, aspect, south, near a 9-foot wall, will good gravelly loam, appropriate soil and damp, but garden very sheltered and sunny. I want to plant a bed of hardy Lilies, which I wish to be permanent, and can make the soil suitable with peat and rotten cow-manure; but I should like a succession of bloom throughout the summer and autumn. Would it answer to fill the bed on top of the Lily bulbs with *Anemones* or *Ranunculus*, or, if not, are there any other plants which can be grown over the Lily bulbs so as to cover the bare ground, and flower when they are not in bloom, and protect their young shoots from early autumn frosts, and prevent detriment to the Lilies? How many bulbs should be planted together of each kind? Some Lilies are expensive. Would single specimens of the rarer kinds be sufficient? I shall be thankful for any information, and also for a list of the best hardy Lilies to be obtained at a moderate cost. How far apart should Lilies be planted?

bulb from bulb, and how deep, and is horse-manure 6 inches or a foot below the bulbs injurious or beneficial? Is it best to grow Lilies in a bed by themselves or in clumps in a mixed herbaceous border?—LEICESTERSHIRE.

REPEATED QUERY.

5096.—Treatment of Cape bulbs.—I should be much obliged if J. C. C. (who kindly advised me as to treatment of Cape bulbs in spring) or anyone else who could tell me how to treat "Crinum asiaticum," which was supposed to be "aquaticum," and placed in a pond all summer? It flowered well and bore seed, which was planted in pots in a conservatory, and they have come up. Should the first spears be reported now to give them more space, and should the old plants be still left in water (they are now in a tank under glass) or allowed to dry?—Tm.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5097.—Odontoglossums (C. Drinker).—Perhaps the following would suit you: D. Androsolanum equitatum, Coranense, Italicum, hastulatum, luteo-purpureum, Melius, nebulosum, Ross majus, Roezli, Roezli album, Uro-Skinneri.—M. B.

5098.—Colognes cristata (George Elford).—This should be kept mild and in fair heat, but you must be anxious not to keep it too wet, or you will stand the chance of losing the spikes entirely.—M. B.

5099.—Odontoglossum Harryanum.—H. Hardy sends me an excellent variety of this fine plant, but it appears to have the mirror-like falling of the species, and that is, the petals are very slip-slippery. You should put your hands between the petals and spread them out.—M. B.

5100.—Lapagerias from seed (T. R.).—Sow the seed as usual in pits in well-drained pots or pans filled with sandy peat, lightly cover the seed with a little of the same soil, and place pans in shady part of rather warm greenhouse. Keep soil moist.

5101.—Worm-casts on lawns (N. T.).—Brush the casts off. You had better not kill the worms, but if you think to do so there is nothing better or safer than clear lime-water. A bushel of quicklime will do for 50 gallons of water. Stir it up and let it stand until the lime settles to the bottom, leaving the water quite clear. Use this clear water to water the lawn, and the worms will either come up to the surface in die or will die under ground.

NAMES OF PLANTS AND FRUITS.

Any communication respecting plants or fruits sent to this office should always accompany the parcel, which should be addressed to the Editor of Gardening Illustrated, 37, Southampton Street, Strand, London, W.C.

Names of plants.—J. Richmond: 1, Lilia aurum; 2, Corleya lahitia; 3, Cyrtanthus lauratum; 4, Cypripedium parviflorum;—E. H.: Mohria thurifera; 2, Nepenthes distachya; 3, Microlepia Nova Zelandica.—C. James: 1, Sophronitis bilobata; 2, Odontoglossum Harryanum.—G. Cassell: We cannot undertake to name Chrysantheum. Send them to a large grower.—M. H.: Adiantum tenerum; 2, Adiantum gracillimum; 3, Cichanthus arcytes.—C. M.: Odontoglossum oclatatum, pale variety.—S. H.: The flowers of Chrysantheum sent were crushed out of all recognition.—L. Agar: Chrysantheum "Jardin des Plantes."—Debat: 1, Spartanium africana; 2, Send fresher specimens; 3, Acacia longifolia.—J. F.: Adiantum concoloratum.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake in some few varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of Gardening Illustrated, 37, Southampton Street, Strand, London, W.C.

Names of fruit.—O. S.: Pear Bonnet de Capitan. —Mrs. Bell: Small highly-colored Apple, apparently King of the Pippins. Other one, Five-crowned or Lemon Pippin. Please number specimens in future. —H. M.: Light-red, Wisbech.—Apples: Royal Russet; 2, New Hawthornden, Fens; 1, Althorpe Crassane; 2, Old Crassane.—S. B.: Apples: 1, Not recognised; 2, Warner's King; 3 and 4, Yorkshire Beauty; 4, Lemon Pippin; 4, Five-crowned Pippin; 7, Not recognised; 8 and 9, King of the Pippins; 10, Royal Russet; 11, Cox's Orange Pippin; 12 and 13, Rotten. These were all bad specimens; and in future please only send six kinds for naming. —Mr. H. S. Traver: Apples too much shrivelled to name.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to furnish answers to queries unless they contain the name and address of sender.

Chesnut.—Apply to Messrs. Richard Smith & Co., High Street, Worcester.—Bayonet.—Please repeat queries, and write each one on a separate piece of paper, and on one side of it only.—Constant Reader, Helensburgh.—Mr. B. C. Ravenscroft's address is Field Wood, near Crawley, Sussex.

POULTRY AND RABBITS.

5094.—An incubator.—Will anyone who has had practical experience of an incubator kindly give me full particulars as to cost, management, &c.?—Vern, Black-wear, Petersfield.

Drawings for "Gardening."—Readers who kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner and will appear in the next issue of Gardening Illustrated.

THE CONICAL BOILER is the Cheapest, most efficient, and Economical Boiler ever invented. For heating Greenhouses, Conservatories, Warehouses, Churches, Chapels, and for Amateurs' Hothouses. Requires very little attention. Will burn any kind of fuel, and cannot burn hollow. Sole Makers: NEWBURN, WOOD, & DYSON, BIESTON ROAD, LEEDS. Prices and Testimonials on application.

PROTECT YOUR PLANTS FROM FROST. The RUSSIAN MAT IMPORTERS' CO. are now Selling for Cash with Order—NEW SEASON'S ARCHANGEL CARGO MATS, at 100s. per 100, or 10s. 6d. per bundle of 10. NEWEST PATENT RUBBER CARPET MATS, at 50s. per 100, or 5s. 6d. per quantity of 10. (Special Quotations for Large Quantities.) 40, GREAT TOWER STREET, LONDON, E.C.

PEARCE & HEATLEY

CONSERVATORIES, GREENHOUSES, CUCUMBER FRAMES 'HOLLOWAY' BOILERS.

Complete Apparatus with 4-in. pipes, flow and return, along one side cut and fitted; so that if the internal measurement of the Greenhouse is given, the Apparatus will be sent complete, ready for fixing, carefully packed for rail at the following respective prices—30 ft. by 10 ft., £2 10s.; 30 ft. by 6 ft., £3; 10 ft. by 7 ft., £3; 12 ft. by 8 ft., £3 5s.; 15 ft. by 10 ft., £4 5s.; 20 ft. by 10 ft., £5 5s.; 24 ft. by 10 ft., £6 5s. For other sizes and prices of Boilers see List.

New Illustrated Catalogue 3 stamps, List free, £2 BEST WORK ONLY AT REASONABLE PRICES. The North London Horticultural Works, HOLLOWAY ROAD, LONDON, N.

JONES & ATTWOOD.

Supplied with various arrangements of Pipes. For Greenhouses, &c. Catalogue free. James Trowie, "Heating by Hot-water," 120 Pages, 50 engravings. Cloth, 2s.

HEATING APPARATUS, From £4 4s. and upwards.

Full Particulars and Local Agent's Address from R. JENKINS & CO., ROTHERHAM.

FIRST-CLASS SILVER BANKSIAN MEDAL. Awarded by the Royal Horticultural Society, 1893.

AMATEUR'S FRIEND, 10s. AMATEUR'S ASSISTANT, 20s. PRINCESS APPARATUS, 20s. DUCHESS APPARATUS, 30s. CHAMPION & PERFECTION BOILERS, PROPAGATORS, FRAMES HEATERS, FOG EXHAUSTERS, &c. SEND ONE STAMP FOR LATEST ILLUSTRATED CATALOGUE.

NO FLUE REQUIRED. (SAYLOR PATENT.) COMPLETE SATISFACTION GUARANTEED. C. TOOPE & SONS, STEPNEY SQUARE, LONDON, E.

Improved Condensing Greenhouse Heater, for Gas, 35s.; for Oil, 41s. THE CAMP MANUFACTURING CO., 12 and 14, Leonard-street, City-road. LONDON.—BENNETT & CO., Chesham, and all Ironmongers throughout the Kingdom. Write for Prospectus. URBANA-CHAMPAIGN

CHRYSANTHEMUMS.

PREPARING FOR NEXT SEASON.

A DIFFERENCE of opinion exists amongst growers of Chrysanthemums for large blooms as to the proper time to insert the cuttings to obtain the best results. Many aver that the early part of March is soon enough, but seldom are these advocates of late propagation seen occupying a foremost position on the exhibition table. To cultivate Chrysanthemums really well it is absolutely necessary that the plants have a long season of steady, uninterrupted growth, and without the cuttings are inserted in good time it is not possible for the plants afterwards to have this. If the plants are struck late, and hurried on by leaps and bounds, as it were, to make up for lost time, how can the growth be matured? And it is from plants with mature stems that the finest blooms are obtained. Plants that are strong, yet soft and supple, may give blooms of great width, but they will lack the most essential points of quality—viz., depth and solidity. Without these two latter the blooms are not perfect. Especially is the incurved section affected in this way. Take, for instance, any member of the Queen of England family. Certainly this is the finest type of an incurved Chrysanthemum we have. Plants immature in their growth never can produce blooms of representative quality; more often than not the petals reflex instead of incurving toward the centre as they ought. In nine cases out of ten this is the result of not striking the cuttings early enough. From long experience and close observance of other people's practices I am convinced that there is no better time to take the cuttings than from the middle of December to the same time in January. The former month is preferable, but it so often happens that cuttings are not available just then. Where a cultivator provides his own stock, there is no reason why the cuttings should not be in readiness at the time stated, except, of course, in a few stubborn instances. If my instructions on page 516, relating to the preparation of cuttings, were carried out, the sucker-like growths from the base of the old roots will now be arriving at a state of fitness. Where too many growths have started remove those that are weakly, admitting more space for the others to become stocky. Attend well to cleansing them from aphides, both green and black, by a free distribution of Tobacco-powder. Provide the plants with abundance of air, and not too much water at the roots, or paleness of the leaves will be the result. The necessary number of 2½ inch pots can be got ready by washing them quite clean. I am not an advocate for the employment of dirty pots, not only from the appearance point of view, but from the cultural value of clean pots. When plants are placed in pots that are dirty inside the roots adhere firmly to the pot, and when the plant is turned out of the same, with a view to transferring it to a larger size, the roots are very often broken by their adhesion to the pot.

Anything like this is liable to give a check to the growth of the plant, which is bad for its ultimate success, but very much worse when in its infantile stage. If the pots and crocks are got ready, and the compost, loam, and leaf-mould placed under cover, so that when used it will be in a fit state to handle, the work of inserting the cuttings will be much facilitated. In the next issue of GARDENING I hope to give definite instructions as to the best method of propagating the plants, as in this phase of the subject I fear many amateur cultivators are lacking in knowledge. Without a fitting formulation is laid it is hardly possible to expect satisfactory results.

E. MOLYNEUX.

5070.—Chrysanthemum-cuttings.—It is wise, after this season, never to lose a strong cutting of a good variety. They are not much trouble to strike if the frost is kept from them, as they require no artificial heat. To obtain large blooms it is necessary to strike early; but for ordinary decorative purposes cuttings rooted in February will do very well, bearing in mind that strong, healthy cuttings should not be lost sight of.—E. H.

— If the plants are to be cultivated with a view to produce large exhibition blooms, the cuttings should be inserted any time during the present month, with a view to allowing ample time to make a steady growth. If a quantity of blooms are preferred to individual quality the first two weeks in January will be early enough for this purpose.—E. M.

— The cuttings should be put in now. I find they do well in a moist place, and the best position is the cool orchid-house. They are placed singly in small flower-pots. Plant each one singly and firmly in the fine sandy soil, and place some sheets of glass over them at first to prevent their flagging. A few of the incurved varieties may be put in early in January.—J. D. E.

5072.—Disbudding Chrysanthemums.—As a rule, it is proper to "take" the crown buds to obtain large flowers, but there is no rule without an exception, and with Chrysanthemums the rule may be frequently broken with advantage. This matter requires both study and experience. Good blooms of certain varieties can only be had from the crown-buds, and in these cases the side shoots should be pinched off and the crown-buds left, if they do not show too early, which sometimes they do. There is a certain best time for taking the bud, as it is termed (though it virtually means leaving the bud and taking away the side shoots), and if these come too early the bud is removed and one or perhaps two of the side shoots left, and the best terminal bud taken. On the other hand, there are a few varieties, including some of the Incurves, where it is better to pinch off the crown-buds and trust to a good terminal. Good flowers are and can be obtained from dwarf plants by two methods; first, by cutting down in May and taking up one or two shoots with one flower to each; and, secondly, by striking the leading shoots in August in a close frame where there is a little bottom-heat. By the last plan very dwarf plants may be obtained, but only one bud on each shoot should be left.—E. H.

If large blooms are wished for, remove all buds but the central one on each shoot. These buds produce finer blooms than any of those

coming from the side of the shoots. Fairly large blooms can be had from plants made dwarf by cutting them down, but they lack solidity and depth as compared with those produced from plants more naturally grown. Varieties that are of a dwarf habit of growth, as, for instance, Mrs. Falconer-Jameson, will give excellent blooms from plants but 3 feet high. If exhibiting is the object of cultivating I advise that the plants be managed so as to each produce three stems and the same number of blooms.—E. M.

5078.—Chrysanthemum-suckers.—If the suckers can be taken up with a few roots attached to each towards the end of the month and put into small pots they will succeed quite as well as cuttings taken off in the orthodox manner. When the suckers push through the soil a few inches away from the stem, they can be taken off with roots attached, but when they spring direct from the old stool under the soil it is seldom that they have roots attached.—E. M.

The suckers at the bottom of the old plants may be taken up with roots and treated the same as root-cuttings.—E. H.

5036.—Names of Chrysanthemum.—Although both varieties belong to the Japanese section they are quite distinct. Source d'Or: This is the most popular variety grown for decoration, either in a cut state or as a plant. The colour is bright-orange, shaded gold, with semi-drooping florets. Flowers rather under medium size. Boile d'Or: Three or four years ago this was one of the most popular varieties for exhibition, but being rather difficult to cultivate really well, it is not nearly so much grown at the present time. The blooms are large, florets broad, long, and partly twisted. Colour, yellow, striped bronze.—E. M.

— The varieties Boile d'Or and Source d'Or are quite distinct from each other, and both are very useful and handsome kinds. The former produces very large flowers, with broad petals, rich-yellow, twisted, and striped bronze, whilst those of Source d'Or are rich-yellow, shaded in the lower florets with chestnut-red. This is the great market Chrysanthemum, and one of the finest varieties in cultivation, the flowers being produced in graceful sprays. It is largely grown for market, and is always welcome to its freedom and rich colour.—C. T.

— Source d'Or and Boile d'Or are very distinct: the first is more of a bronze than golden, Boile d'Or flowers later.—E. H.

5014.—Japanese Chrysanthemums.—The following would make a very good selection, and all were shown well at exhibitions during the past season: Colonel B. Smith, a big flower, like all the remainder, and bronze in colour; J. Stanborough Dillen, E. C. Clarke, G. C. Schwabe, Beauty of Castle Hill, Avalanche, C. H. Wheeler, Viviani Morel, John Shrimpton (deep crimson), W. Seward, Sunflower, Avalanche, C. H. Wheeler, W. W. Coles, Mlle. Marie Hoste, Alberic (a fine deep-crimson flower), Eda Prass (one of the most recent novelties, white, and touched with a delicate rose colour), Charles Davis (the bronze coloured sport from Viviani Morel), Etoile de Lyon, E. Molyneux, W.

Tricker, W. H. Lincoln, Mrs. Hattana Payte, Violet Rose, Miss Dorothy Sher, Mlle. Therese Rey, and Lord Brooke. Everyone of these, almost without exception, is new. Of the incurved you cannot do better than select M. F. Bahaunt, the new purplish rose-coloured incurved, the flowers are large, coarse, and not to my mind attractive, but still they are to be seen in all leading collections. Empress of India, Princess of Wales, Lord Wolsey, J. Lambert, Mrs. Robinson King, Ami Hoste, Novelty, Alfred Lyne, Queen of England, Jeanne d'Are, Baron Hirsch, Mue. Darrter, J. Doughty, Alfred Salter, Miss Haggas, Golden Empress, J. Doughty, Mrs. Heale, Novelty, and R. Petfield. These kinds endure considerable variety in colour, and include the finest of the more recently acquired sports and seedlings.—C. T.

5008. — **Striking Chrysanthemum cuttings.**—It is possible to strike the cuttings in an unheated greenhouse, but actual frost ought to be excluded by some means, such as covering to the glass, &c., or they will be a very long time before cutting roots, and may fall altogether. Without a little artificial warmth damp is always very troublesome, at least until the days become appreciably brighter and the sun gives more power. The most suitable temperature in which to strike cuttings of these plants is a range of 45 degs. to 50 degs., or 55 degs. They will root readily in a compost of three parts of sandy loam, mixed with two of leaf-mould and some sharp sand.—B. C. R.

GARDEN WORK.

Conservatory.

There is no lack of flowers for Christmas decoration. The most lasting and, therefore, the most useful flowers are the Chrysanthemums, of which there are still plenty. Christmas Roses are also very useful, and large clumps in good-sized pots will yield many flowers for cutting. Double White Primulas are very full of blossoms. The large-flowered whites are the most useful, as the blooms, when mounted on wire, can be used in various ways. Roman Hyacinths, Tree Anemones, Ranunculus, Magnolia, Zonal Pelargoniums (the double are the most lasting), Cyclamens, Heaths, Azaleas, Armist. Lilies, &c., can be had in quantity now, when the arrangements are allowed. Foliage is often a weak point at this season. Mahlen-hair Fern, unless grown rather cool and in a light position, is not very lasting. The fronds of *Pteris cretica* and its varieties come in useful now, and some of the outdoor trees and shrubs may be used. The Evergreen Ferns in variety, including *Darwinia*, *Ulex*, *Empetrum*, and *Aquifolium* are all useful for decoration purposes. The Ivy and *Vincus*, especially *V. elegantissima*, will yield a good many drooping sprays. What is really required is something that will last several days. I have often used *Vincus elegantissima* in pots for filling baskets, and a good stock of well-trimmed plants has considerable value just now. The same may be said of the various forms of variegated *Euonymus*, which may be grown in a cold-house, the hardy *Bauhinia*, and there is a striped-leaved *Pumpkin*, rather nice when well-grown in pots for decorative work at Christmas. Tender forced things are soon used up at this season, and something tolerably hardy is required to form backgrounds. If there is plenty of graceful foliage to set off the flowers one does not mind so much even if the latter are not present in such immense bank-like bloom as we had in the Chrysanthemum a short time ago. A well-grown *Cannella* forms an excellent centre-piece for a change; but it is always more or less stiff, and a series of centres of this kind would be rather too stiff and formal for our present day ideas. *Palms* and *Tropeas* are always appropriate fillings in material; but such things are expensive to purchase, and they soon get too large for the small conservatory. There is not much getting to do now, and what work of this kind there is may be put back till the days begin to brighten. *Abutilons* are very useful in large houses where they can be situated out and trained up somewhere. In small houses they do not meet with so much favour. A stock of loam, peat, and straw-mould may be got in to be ready when required.

Stove.

Foliage plants will come out steadily now, and are among the most useful things for table and other decorative work indoors. *Crotons*, *Drapacnas*, *Amlia*, *Panikums*, the variegated *Cyperus alternifolius* is a charming thing when well grown, being so light and elegant. *Asparagus plumosus* and its varieties is a beautiful thing when well done, and anyone can easily have it in good condition, and it does not require much heat. The intermediate-house will suit it better than the stove. When a plant gets shabby from its cause it is down, and when it has a new and better growth will spring up from the bottom. For furnishing long sprays for cutting the planting-out system should be adopted. A small house with a dozen plants in it trained up wall or rafters would be a joy for a very long time at a very small amount of trouble.

Mushroom-house.

This structure cannot be too large, as so many things may at this season be grown in it. Besides Mushrooms, *Senkale* and *Rhubarb* may be brought forward in quantity, and *Chicory*, *Dandelions*, and *Endives* may be blanching as required. I have often started *Lily of the Valley* in the

mushroom-house, and *Asparagus*, when grown in small quantities in baskets or boxes will come on very well in the genial temperature without light, and the more Mushroom-beds made up the better, as when beds are made up in succession the fermenting manure will keep up the temperature of the building without much fire-heat. Of course, none of the things named will grow without heat, but when a number of beds are coming on in different stages, if the house has been well constructed, very little fire-heat will be required. Where Mushroom-beds are grown on a large scale there is no time to be spent particularly about the fermenting of the manure, as is commonly done in private gardens, and neither is this necessary. If the longest litter is shaken out and about one barrowful of good loam is added to every four or five of manure, the whole well blended together, and the bed made up as soon as fermentation sets in, there will be no cause to complain of the crop if the spawn is good.

Early Cucumbers.

Seeds should be sown now to obtain plants to put fruit from early in March next. Sow one seed in each small pot and plunge in a propagating-case in a warm-house where there is a brisk bottom-heat. As soon as strong enough shift into larger pots and have the pits made ready for their reception. Do not crowd the plants. In the long run more seeds will be put from plants that put apart than if nearer together. It is a good plan to place a layer of good manure over the bottom of the chamber, and the same thing may be done if the bottom-heat pipes are laid in rubble. This layer of manure (I always use Moss-litter manure) is a great source of nourishment to the plants all through the season.

Forcing-house.

Vines in pots may be started now to produce ripe grapes in June. The best forcing varieties are the Black Hamburgh and Foster's Seedling. Plunge the pots in a bed of leaves, if possible. The roots will work out into the bed, and there will be a chance of feeding them there without deluging the pots of soil with strong liquids that have a tendency to make the soil sour. Bend the vines back to make them break well, and if this does not succeed give the single starters a heel by taking the cut of the cane in the hand and twisting it until pressure is brought to bear upon the tissues all down the stem. So far as my experience goes this never fails to liberate and set the sap in motion.

Window Gardening.

Chinese Primulas, *Geraniums*, and *Cyclamens* are very effective Christmas flowers. *Solanums*, *Antirrhiums*, *Anemones*, and *Pernettyas* will furnish a lot of bright-coloured berries. *Roman Hyacinths* and other bulbs will do very well in the warmest room. The early-potted *Freesias* are now showing flower, and with me they are stronger than usual this year.

Outdoor Gardening.

Laurels and other evergreens may be pruned now—so far, at least, as the knife can do so; but if oil laurels require to be cut down the work should be put off till March, otherwise severe frost may kill the joints. The pruning, made in the early part of the year, is a good thing, and makes the plants more compact for planting under trees where the shade is not too dense. They are also suitable for planting on sloping banks, to be kept luxuriantly pruning. The common green *Lilly* is a good shrub to plant in shady places; but in all cases where planting under trees the ground should be broken up and some fresh soil placed on a top-dressing. *Hydrangeas* borders, especially those containing lilacs, should be mulched with old manure or a mixture of manure and rotten leaves. Continue to remove weeds from lawns, and if the Grass is weak and thin apply a manured dressing of some kind. Many lawns have severely suffered from the scorching received last summer. It is getting too late to plant bulbs now, but if there are any *Tranons*, *Snowdrops*, or *Daffodils* still out of the ground plant them in the Grass, at the foot of trees, or in sheltered nooks on the lawn. Where this is done freely the effect is very good. Much of the recently-planted *Roses* and shrubs, and see list all full things are properly watered. Take up and replant *Box-edges*. The small-leaved *Box* may be used for edgings when cut in occasionally. It furnishes a very neat edging. I have seen the common *Evergreen Malva* used in a similar way. Small plants are very cheap, and these things afford a pleasant change from *Box* or *Tiles*. Plough the bottom of evergreen and other hedges.

Fruit Garden.

If the pruning and training of wall or other fruit-trees should be in arrears make every effort now to overtake the work. See that *Figs* are properly protected before severe weather sets in. *Figs* are not safe without protection. Any where away from the south coast *Strawberries* may now be prepared for forcing by top-dressing and dipping in a solution of Fishmeal Compound. The dipping will not take long, and it may save some trouble from insects later on. The eggs of red-spider, after such a hot, trying season, may be on the leaves, and at any rate a dip will do good. See that the borders of the early *Peach*-house are thoroughly moist. This can only be done by stirring the soil here and there with the fork, and if found dry mulch the soil with liquid-manure. Soil-water is a good thing to use. When a *Peach*-border gets overcast it is not possible to get any more fruit in the border, and if it cannot be drowned out, and a little silt in the water is a good thing. It is difficult to maintain a border properly when dry, and it is not unlikely there may be more dry spots than usual after such a dry season. Houses built on the oil-fashioned principle with movable lights may have been thrown open to the weather, and in such cases there will be less cause for anxiety. All late *Grapes* may be cut now and bottled. This process has been often described, and *Grapes* will keep better in a dry, cool-room, or, say, a steady temperature of 45 degs. to 50 degs., than in a house where the fluctuations are greater, and, where possible, plants requiring water are stored. Keep *Pot-Vines* just started in a genial temperature of 50 degs. all night, with, on the average, a 10 degs. or 15 degs. rise in the daytime. Keep the canes bent back to induce all the buds to break.

Vegetable Garden.

The forcing gardener will be busy now, *Asparagus*, *Senkale*, and *Rhubarb* may be had in quantities. The only limit will be space and suitable roots. *Asparagus* also

should be plentiful from open-air beds, as well as from beds made up in Mushroom-sheds and cellars. In making arrangements for new houses for Mushrooms, have them as much as possible below the surface; the Mushrooms will do better, and less artificial heat will be required. Mushroom-beds may be watered freely with weak liquid-manure. After gathering commences autumn and winter salads require a good deal of watching. A full-grown *Lettuce* is soon decomposed if exposed to frost, and another is not much harder; shelter of some kind is absolutely necessary; the same remark applies with equal force to *Late Cauliflowers* and early *Broccoli*, *Vetch's Autumn Self Protecting* is a very useful *Broccoli*; never disappoints, but though in a sense self-protecting, in the arrangement of the leaves over the hearts it is not wise to expose it to frost after this date. It is a very easy matter to protect them by stripping off a few of the bottom leaves, taking the plants up with balls, and planting them in trenches with heads sheltered over to the north. Where frost is expected cover with mats or litter. Late sown *Turn Carrots* must be protected from frost. They will keep very well in the ground if covered, and they are better fresh drawn than taken up and stored, and if the weather keeps open they will make a little more growth, but it should be borne in mind that frost will spoil them. A little dry *Fern* scattered over them will keep them safe for some time—at any rate, and if very severe weather comes, cover with mats or excelsior over the litter or *Fern*. Where old plants of *Tomatoes* are kept on to ripen late fruit, if the white-fly appears deal with it promptly by fumigation. E. HOUAY.

Work in the Town Garden.

Now that the days are at their shortest, and the growth and vitality of plants at the minimum, bedding and greenhouse subjects of most description ought to be kept as quiet as possible, and not excited by means of a undue amount of warmth. In the murky atmosphere and defective light of a large town any considerable extension made at this season will be devoid of the necessary substance, and hence exhausting rather than augmenting the strength of the plant. Of course, such things as *Roman Hyacinths*, *Tulips*, *Narcissus*, *Cyclamens*, *Epacris*, and others now coming into bloom may fare, and will, indeed, be all the better for, a little extra heat, and in practice I have found it better to keep them in a somewhat warmer glass than is necessary in an open country place, because, possessing less vitality and vigour, they require greater care and more favourable conditions in all respects; but, in any case, the night temperature at the greenhouse proper ought not to exceed 45 degs. for the next six or eight weeks at least. The watering too must be very carefully performed now. In a low temperature too much moisture at the root is worse than too little; but though it is all very well to keep plants comparatively dry in cold weather, if carried to excess this often does a lot of harm, for the tender rootlets soon perish in a really dry medium, and then the plant suffers. In warm houses, where much artificial heat is used, it is a great mistake to be too sparing with the water-can, this quickly leading to enfeebled growth and hosts of insects. No repeating should be done now for too disturb the roots, or present them with a mass of inert soil to penetrate in their present stagnant condition would be dangerous in the extreme. Wait until the days gain greater length, and the sun more power again for all work of this kind; but in the meantime composts may be prepared and placed on the border, pots washed and dried, and boxes mended or repaired. Insert *Chrysanthemum* cuttings, certainly of the Japanese varieties, as fast as they can be obtained; the best cuttings are often the strongest, and even if a plant is too forward for show in any way, it can be pinched twice or thrice, and will make a fine decorative specimen, or be utilized for the production of pin-flowers. Do not keep the cuttings too warm, nor, on the other hand, allow them to experience the least touch of frost, and prevent flagging by every possible means. Obtain and pot roots of *Spiraea japonica*, and *S. palmata*, *Hydrangea paniculata*, *Lilacs of the Valley*, and also of *A. stratum*, *L. lanceolatum*, *L. longiflorum*, &c. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from December 16th to December 23rd.

Moved shrubs, *Spiraeas*, *Lily of the Valley*, bulbs, &c., into a forcing-house. Put in more cuttings of *Chrysanthemums*. I am striking the cuttings in single pots in a frame in a cool-house, where the frost is only just kept out. Carted loam for re-making a *Vivae* border. Shall lift the *Vines* and rearrange the borders next February, and in the meantime the canes will lie and benefit from the exposure. Cut late *Tranons* and bottled them. Pruned and cleaned *Vines*. Rubbed off loose bark and washed the rods with Gishurst Compound, 6 ounces to the gallon. This strength will kill all insects, both in the shape of eggs or larvae. Turned over a gravel walk that had become green with Moss from being overhung with trees. This turning, with a little fresh gravel on the top, will give us a bright, clean, firm walk for some time. The roller will be used till the surface of the walk is hard and firm. Took up and renewed worn turf on *terraces*. Mulched beds and borders of bulbs with old leaf-mould. Dipped *Pelargoniums* in a solution of Sunlight Soap and Thawee-powder. Put small stakes to *Freesias* just showing bloom. My *Freesias* are better than usual this season; the bulbs larger and better ripened. On the other hand, the *Spiraeas* are not so strong. The sunshine which ripened the *Freesias* checked the growth of the *Spiraeas*. Reported a few early-starting *Gloxinas*. The bulbs are starting into growth, and there is no advantage in prolonging the rest when the plants are restless. The bulbs starting now will be in bloom in February. There is no difficulty in flowering *Gloxinas* so soon. It is only a question of resting early, and keeping the bulbs cool when at rest. Many so-called store bulbs are kept too hot and too dry when at rest, and the growing powers are weakened thereby. *Caladiums* sometimes get the dry rot from the dry heat in which they are rested. Moved the first batch of *Strawberries* into forcing-pit. They

* In cold or northern districts the operations referred to under "Garden Work" may be done from the day on a fortnight later than in the districts to which this book refers.

will be brought on steadily at first, night temperature 50 degs. for the first fortnight, and not too much water given. If watered too freely the plants rush into foliage at the expense of the spikes of blossoms. If there are any suspicious of red-spider or green-fly the plants are always dipped in a solution of Sunlight Soap. This is a grand cleansing agent, and so cheap, too. Busy pruning and nailing wall-roses. Want to get as much of this work done before Christmas as possible; so many other things are waiting for us after Christmas. Rearranged rubbish yard, and made a fire of a lot of cuttings, and afterwards, when the fire had got a pretty firm hold, other less combustible rubbish was placed on the heap. The heap will probably be some days before it is burnt out. Fresh material being placed upon it daily. Placed a lot of early Potatoes in boxes in heat to get them sprouted ready for planting in frames shortly. Started a fresh lot of French Beans in 8-inch pots, five Beans in a pot. Planted more Cucumbers seeds in single pots in heat. From this onwards I shall not be without strong Cucumber-plants for making good blanks in houses, or to plant fresh houses if desired. I expect it is only fancy, but sometimes I think when one has a surplus of young vigorous plants, those set out seem to start away and do better. Sown Tomato-seeds of several approved kinds, including Ham Green Favourite and a good strain of Old Red.

THE KITCHEN GARDEN.

PEAS AND THEIR CULTURE.

VARIETIES of Peas, like all kinds of produce for which there is a large demand, are continually increasing, so that to make a selection from catalogues has become a hopeless task. Starting with early kinds, except for the first few gatherings, the earliest section of Peas is scarcely worth growing when compared with the rich melting flavour of the Marrows that come in later; but as the aim of most growers is to get Peas as early as possible, a sowing is generally made of one or other of the small round kinds about the middle of January. My favourite is Ringleader, which, although an old variety, is still one of the earliest and best, a good cropper, and very hardy. Laxton's William I. is early, and, being of good quality, it is a desirable Pea to cultivate. American Wonder (here figured) is an excellent kind. As a dwarf-growing, free-bearing, compact Pea for sowing on a warm, sheltered border, Maclellan's Gem is unsurpassed, for not only is it a most prolific bearer, but it is everything that can be desired when cooked, and it has all the good qualities which a dwarf, early sort can possess, and from not being more than about 2 feet high, a few twiggy sticks suffice for its support, a consideration near towns where Pea-sticks are difficult to obtain. For sowing in open quarters to succeed the first entries, there is none that equals the old Alvincer, which is really, in every respect, a first-class Pea. This variety grows to the height of about 3 feet, branches freely, and bears nearly up the entire length of its main a number of well-filled pods, the Peas in which are of good colour and delicious flavour. To follow in the heels of this, a sowing of Veitch's Perfection should be made about the same time, and, where a regular supply is wanted, continued at intervals of a fortnight till the middle of July. Take it all in all, this is by far the best dwarf Pea in cultivation; but one mistake which many make is sowing it too thickly, a circumstance which, on account of its robust, free-branching habit, causes the plants to become so thick and crowded as to spoil the crop. In good,

The advantages of this will be obvious at a glance, as the one prepares the ground for the other. To grow Celery well the trenches must be heavily manured, of a portion of which the Peas get the benefit, and the deep digging necessary for its cultivation and in taking it up, is just what the after crop requires, as the roots can penetrate far down and be in a measure independent of the weather or other aids for a supply of moisture. The readiest way of getting early Peas is to sow in boxes or pans of finely-sifted leaf-soil, and to place them in any vacant situation under glass where they can be kept close till they germinate and get fairly up, when they must be set well up to the light and have plenty of air to prevent them from becoming weak or drawn, which they soon would do if at all thick. Various other plans have been adopted in raising early Peas, such as sowing on strips of turf and in drain tiles filled with soil, but both take up much more room, time, and labour, and are not one whit better, as Peas transplanted just as readily and safely from the leaf-soil as when treated in any other way. By the middle of March, if the weather be anything like favourable, Peas sown in January as just recommended may be safely ventured out in any

Pea "American Wonder." Engraved from a photograph sent by Mr. Norm in Blake, Bedford.

sheltered border or quarter, where they may easily be put into rows by drawing a deep drill by means of a line or chipping one out with the spade so as to admit their roots without being cramped or doubled up. The firmness of the leaf-soil will admit of their being divided to any extent without injury, so that they can be laid in thinly at the time of planting, and when this is done they should be protected by having a few sprigs of small-leaved evergreen stuck along one side of the row to break the force of any cold winds that may occur.

SPRATTOES do much damage to Peas just after they emerge through the ground, or when planted out in this way, nipping off each leaf as it appears till the plants are entirely crippled, unless some effectual means be adopted to prevent their attacks. Nothing answers the purpose better than the galvanised wire Pen-guards that are now sold so cheaply by most ironmongers, as these put them quite at defiance, and if taken care of when out of use will last a lifetime, so that the first cost might scarcely be a consideration, as they do away with all annoyance and disappointment in securing a crop. In cases where these are not at hand, a ball or two of emmet black cotton run up and wrapped about three times, just above the heads of the plants of Peas, and supported in that position by a few small sticks, will generally keep them

at bay, as they become naimed when they are light and find their wings entangled; or the tops of Peas may be made disagreeable to their palates by sowing some dry soot over them while the dew is still on them, an operation which will also answer the double purpose of preserving them from slugs, which this year are more than usually troublesome, and will be so unless we have some sharp frosts to come upon them unawares before they have time to bury themselves in the ground. Besides the above, growers of Peas have other means to contend with, the most formidable of which are rats and mice. After trying many remedies for these, I find nothing equal to paraffin oil, a tablespoonful or so of which is sufficient to soak a quart of Peas, which, when so treated, are left unmolested, and are not in any way injured. It may not be generally known that the

YOUNG GREEN TOTS of PEAS make delicious soup, a luxury that may be enjoyed all through the winter. Of course it will not do to sow choice sorts for purposes of this kind, as that would make the soup come rather dear; nor is it necessary to do so, as any common cheap Pea will do equally well. The best way to treat them is to sow thickly in boxes or pans containing light soil; and if wanted quickly, to stand them where they will get a little heat, when they will soon be up ready for use, which will be directly they are about 1 1/2 inches long. If allowed to get more forward than this they lose much of the delicate Pea flavour, and do not become incorporated with the soup so readily as when they are young and tender. S.

5025.—Growing early Rhubarb.—Provided the roots are strong, "Novice" will have little difficulty in getting good early Rhubarb. Place the pots or tubs over the crowns, then enter them with a good depth of leaves. They will soon get warm enough to excite growth, and there is no danger of getting too much heat so as to injure the crowns, as is the case when stable-manure is employed, and I think the flavour of the produce is better when leaves alone are used; if placed in at once the Rhubarb will be fit to pull about the end of January.—J. G. H.

5098.—Early Potatoes and Brussels Sprouts.—If it is intended to put out Brussels Sprouts between the rows of Potatoes it will be highly desirable that they be planted 30 inches asunder. To obtain good Brussels Sprouts they should not be planted closer than this, and the same distance asunder. To get good early Potatoes they require rich, good deep soil, and this is also the best for Brussels Sprouts.—J. D. E.

—If it is intended to plant Potatoes and Brussels Sprouts alternately, the rows should not be less than 30 inches apart, but I have frequently the early short-topped Potatoes 2 feet apart, and then planted a row of Brussels Sprouts between every second of Potatoes, and I rather like the latter plan best.—E. H.

—I suppose you mean the distance between the rows, not that from set to set in the rows. To allow of the Sprouts being planted between, and the Potatoes conveniently fitted without disturbing them, a distance of 2 1/2 feet to 3 feet ought to be allowed, preferring the latter, if possible. But if you can slip the Potatoes early in June it will be time enough to plant the Sprouts afterwards.—B. C. R.

5053.—Replanting Seakale.—Seakale may be replanted now, but it will do as well if the cuttings are laid in dump sand or earth till March and then replanted. I always use the throngs or roots cut from the forcing crowns to make new plantations. The crowns are lifted now for forcing, and the side roots trimmed off. These latter will be laid in dump sand till March, by which time new rows will be forming. They will then be planted with a dibble in well prepared ground in rows 18 inches apart, and 1 foot apart in the rows. Any good soil well manured and cultivated will grow Seakale.—E. H.

—Seakale may be replanted any time before it starts into growth in the spring. Plant in rows about 18 inches apart, and allow a foot or so between each plant in the rows. Seakale does best in an open garden soil, deep and rich. I find it does not succeed well in clay loam, unless plenty of open soil, such as road-scrappings, siftings from the potting-shed, &c., is placed around the roots. Even coal-ashes is excellent material to mix with clayey loam for Seakale, and for such soil plenty of good stable-manure in a decayed state should be used, and some ashes around the roots is beneficial.—J. D. E.

Original from March is a good time to re-plant Seakale. The soil should be trenched 18 inches deep, and, during some partly

rotted manure to the top spit of soil. It is useless to bury it deeper than this, as the roots would be encouraged deeper in search of it. If the soil is heavy and retentive of moisture the top spit of soil should be kept in the same position after trenching, thoroughly breaking up the soil at the bottom of the trench and leaving it there. Dig up the roots carefully, cut off the crown just below where the leaves spring from. This is done to prevent the growth developing a flower-head, which weakens the crown for future use. By cutting off the tops extra crowns are formed, which gives more produce. When planting, fork over the ground and chop out a trench with a spade to enable the roots to be laid carefully in in rows 18 inches wide, allowing a space of 15 inches from plant to plant.—S. P.

HERBS.

As a rule, these very useful plants are but little cared for until they are wanted, and then it is by no means rare, even in gardens of good size, to find but very scanty provision for the supply of herbs. It appears as if the great care bestowed on some crops militates against such humble every-day plants as these receiving even the little attention they require. The following herbs are very useful, and can be easily grown in any ordinary garden—viz.,

BASIL ("SWEET") is a herb of annual growth, easily raised from seed; if required early in spring or late in autumn, seed should be sown in pots or boxes under glass; but during the summer months it grows freely in open air. A small patch sown in April, and another in June, will supply a good-sized family.

BORAGE is a much hardier herb, and grows freely out-of-doors, and reproduces itself abundantly by seed. Some of the seedlings should be potted up in October in case of very severe weather; but the greatest demand for it is in hot weather, when it is plentiful out-of-doors.

FENNEL is in considerable demand for fish sauce. It can be increased from seed, and the roots last for years. Some plants should be cut down when it starts to send up flower-spikes, so as to keep a full supply of green leaves.

MINT is in demand all the year, and to get green Mint very early in the new year roots should be lifted in December and placed in shallow boxes of fine rich soil, placing them in any warm-house. Out-of-doors it grows freely in any light well-drained soil, but should be replanted every alternate year, or it dies away if left in one place too long, although it naturally seeks fresh soil by pushing out all round the outer edges of the bed, while the centre, or old part, will get quite bare. For dry Mint the tops should be cut in July and tied in bunches after careful drying.

MAYORAN ("SWEET") is a very hardy and useful herb; it can be increased by division, or by cuttings, and grows freely in any garden soil.

PARSLEY is one of the daily wants of a kitchen, and unless a good supply be on hand it causes a deal of trouble. A good sowing should be made in March, and another at midsummer. For winter and spring use the latter should be in a position where shelter can be easily given. Thatched hurdles are best protectors from snow.

SAGE is used both in a green and dried state; for the latter it is cut in July and hung up in bunches. In a dry airy place it is a very hardy herb, and can be cut green all the year round, and the plants are beneficial by cutting back.

TARRAGON is much prized by some kitchen authorities, but it will not grow freely in all kinds of soils. I find old mortar-rubbish and road-grit mixed with the soil suit it well; it forces readily in gentle heat.

THYME AND **LEMON THYME** are much used, and should be grown in every garden. As they are of easy culture they increase readily from seed, or by division of the roots, and require transplanting every alternate year, or the branches get long and straggling. Cutting back should be done at midsummer so as to get a good head of shoots before the winter sets in.

J. GROOM, Gosport.

TREES AND SHRUBS.

LILY OF THE VALLEY BUSH (ANDROMEDA FLORIBUNDA).

This is one of the best of dwarf shrubs, looking neat and well furnished throughout the year. The flower-buds are formed and considerably developed in the late autumn, so that the little

Flowers of Lily of the Valley Bush (Andromeda floribunda).

shrub looks throughout the winter as if about to burst into flower. The blossoms expand towards the end of March, and remain in beauty throughout April. It is an excellent shrub for a rock garden. The single sprays are valuable for cutting, lasting long in water, and looking well alone or with almost any other flower. It should also be borne in mind that this shrub, if potted up early, will bear gentle forcing well, and the flowers then come of a very fine white colour.

DIGGING AMONG SHRUBS.

There are various opinions upon this point of culture I am fully aware. Now, however, that the time has arrived for cleaning out (or digging in the leaves?), thinking out the plants where worthless and cutting out the dead wood, it is, in my opinion, a subject which may be discussed with profit and advantage. I have thought the matter over year by year for some considerable time, and am myself in favour of light digging among the shrubs as soon as the leaves have all fallen. I might, however, alter my mind if I had to cultivate a clayey soil. In my case it is a fairly light soil with a gravelly subsoil; hence, in only moderately dry seasons the shrubs suffer considerably. By stirring the surface, not deeply, but sufficiently so to bury the fallen leaves, facility is afforded for all the rainfall to percolate the soil in an equal manner. With a smooth (or nearly so) surface, the result of its being left alone for some years, the water cannot penetrate the ground equally, but consequently runs away to the lowest parts. This, I think, cannot but be prejudicial to the shrubs in course of time. Besides, by raking out the leaves and supplying no manure in its place, we deprive the plants of a natural source of food which must be of ultimate good to them. Another point, too, I think, in favour of breaking up the surface is that of the ground not freezing so deeply there as where it is not disturbed at all. This can be noted by anyone during ground work in frosty weather. The disturbing of the surface roots may be advanced against the practice, but I do not think it is at all material, but rather tends to their good, more fibrous roots supplying the place of grosser ones. If

LEFT UNDISTURBED for a few years, the surface becomes in a measure hardened; then in the summer-time, when copious rain falls—as in thunder-storms—take place, much loss must ensue to those shrubs not favourably situated to receive the water. If I have to water shrubs in dry weather, and

the surface is hard, I immediately break it up to direct the water to the required spot. That some things do suffer through the surface being hard is an undoubted fact. Take, for instance, some of the coniferous trees planted upon lawns, but elevated rather than kept level. These in course of time get excessively dry, and that to their detriment. They would not do so if the surface were broken up. The better plan would be to plant on the level and provide for a contingency by means of drains. In some cases the leaves in shrubberies are not disturbed. This, I think, is much better than the raking-out process after the fall of the leaf, only it does not look so tidy at the front. In my case I rarely rake out any leaves, but merely turn the soil over lightly, so as to bury them. This leaves all fresh and tidy-looking, a walk round the shrubberies afterwards being quite enjoyable, despite the bareness of the deciduous shrubs. It may be urged by some gardeners that the work takes time. It does, like everything else with respect to garden culture, but I consider it is time well spent. The let-alone policy with respect to shrubs in general will in course of time leave its mark. Whilst the digging is going on any necessary pruning can be attended to easily, whereas otherwise it might possibly escape notice.

II.

Ivy edgings and carpetings.—Where it has been found necessary to renew turf verges and plots under the shade of trees by reason of the Grass dying off year by year, the use of Ivy in the form of edgings between the walks and shrubs will be found an excellent remedy, as it will also upon bare patches under trees. To me it seems an utter waste of labour every autumn or spring to re turf such spots with the prospect later on, when dry weather sets in, of having to water the turf to make it even presentable. I am aware that to the mowing-machine must be attributed some of the bad appearance where the grass is weakly if so be the mowing is thoughtlessly persisted in after a rainfall and whilst still wet upon the surface. The Grass at such times will be smothered down and the weakly plants further crippled. For such times and places the scythe is still preferable. To recent, however, to the Ivy as an edging I could say that it is not necessary to purchase the plants in pots for this purpose; those, of course, make more show for a little time, but smaller ones well rooted, but lifted without hardly any soil, answer quite as well. I have, in fact, taken the shoots from plants trailing on the ground with but a few roots to them and dibbled these in as an edging, pegging them down close to the soil, very few failing to grow. One or two waterings after planting may be necessary. The Irish Ivy makes the best broad edging, but the smaller leaved forms of the common or English Ivy are preferable for narrow margins. This latter may be chosen from several varieties, as Hedera Helix digitata, H. H. lobata major, and H. H. lucida, or from the variegated kinds. For massing on bare patches, besides the Irish there is H. H. dentata, a splendid Ivy with massive looking foliage. The latter looks best, however, when slightly elevated on old roots. One great advantage with these Ivy edgings, &c., is the saving in sweeping; the wind cannot blow out the leaves, nor can the birds scratch them out on the walks, in itself no small consideration.—A.

5050.—**Pruning a Wistaria.**—If the wall is quite covered with the branches of Wistaria, prune away all the growth of the current year to within a couple of eyes or so of the base. No time is better for this to be done than now. This close pruning in of the young shoots induces the formation of spurs, and from these flower-branches are produced.—S. P.

—The Wistaria may be pruned at any time before the buds start. Do not cut the young shoots close back, but spur them in to two inches or so. The Wistaria often blooms on the spurs.—E. H.

5079.—**Trees, etc., for a Derbyshire garden.**—There would, I think, be no difficulty in getting a good garden of plants, provided the soil and situation are favourable. But about these two important matters you are silent. Get plenty of good flowering trees and shrubs, such as the beautiful kinds mentioned. Hardy Azaleas in a more sheltered position are very handsome, the spreading branches smothered with flowers that are very varied in colour, from white through shades of rose, salmon and Irish to the deepest orange-scarlet.

5038.—**A plague of Sparrows.**—Find out where they roost at night, and go after dark with a bat fowling-net. The numbers may soon be reduced in this way. They frequently roosted walls at night, and also under the eaves of barns, &c.—E. H.

The Snowdrop-tree (*Halesia tetramera*), is very handsome. It grows many feet in height, and produces very freely pure-white flowers, and individually are much like those of the Common Snowdrop, hence the name. Far lovelier in late summer the Syrian Mallow (*Hibiscus syriacus*) is useful, if one avoids the dull dingy-colored forms. *Hydrangea paniculata grandiflora* is a grand shrub for a lawn; its flowers are produced in immense heads, and they are ivory-white in colour. Against a wall the Double Jew's Mallow (*Kerria japonica*, fl. pl.) is very showy in spring, the flowers of the deepest orange-yellow colour. The double white-flowered Cherry is a lovely tree, smothered with rosette-shaped flowers of purest white. Then select also *Lambertia*, the handsome Tulip-tree, the Scarlet Thorn, Siberian Crab, *Magnolia conspicua*, which is covered with its large Tulip-like flowers on the leafless branches, the Mallard, *Olearia Haastii*, the Quince, to grow naturally on the outskirts of the lawn, and not interfered by neighbouring things. Much change in variety (*Philadelphus*), particularly the pretty dwarf, white fragrant *P. microphyllus*, *Rhododendrons*, if the garden is suitable for them, not chalky, the beautiful *Rubus hispida* (black), the *Rubus Rose*, and the species named the Chinese Quelder Rose (*Viburnum plicatum*), which differs from the other in its more rigid habit and deep-green wrinkled leaves, *Virgilia lutea*, and *Weigela*s. Then you may plant *Roses*, such as the *Rose de Gloire de Dijon*, but not tender kinds; *Jasminum multiflorum*, *Clematises*, *C. montana*, and the rich-purple *C. Jackmanii* in particular, *Honeysuckles*, *Roses* (*Gloire de Dijon* and *Chesham* hybrid), *Ampelopsis maritima*; *Ivy*s, the *Pieris Thunii* (*Pyraeanthus*), *Wistaria* and *Vines* make excellent climbers. Hardy plants of many kinds also select, and a list of the best will appear.—G. T.

— Most of the hardy trees and shrubs do well in Derbyshire. I have lately had some things, chiefly evergreens, from a Derbyshire nursery in splendid health. There are several large nurseries in Derbyshire where trees and shrubs are well grown. Before ordering it would be wise to look round.—E. H.

301.—**Laurels.**—No time is better than the present to prune Laurels, as the prunings can be employed for Christmas decorations. Laurels are all the better for annual pruning if the plants have filled their allotted space. If they are neglected in this detail they are sure to become "leggy" and lose their lower leaves, which renders them unsightly. A sharp knife or pruning-shears should be used for the purpose in preference to hedge shears; the latter, of course, cuts the leaves as well as the shoots, rendering them unsightly.—S. P.

— The young shoots of Laurels may be cut back now.—E. H.

— This is not the best time of the year to cut back Laurels. Better leave it until the spring, just before they start into growth.—J. D. E.

SHRUBBY NEW ZEALAND SPERDWELLS (VERONICAS).

Of the numerous plants introduced of late years shrubby Speedwells take the lead in point of numbers, over sixty distinct species (not including varieties or forms), according to the latest botanical authority, being found there, and of these, perhaps, half are in cultivation in our gardens at the present time. The only thing urged against their being largely planted is their liability to be disfigured during severe winters; but I believe this is true only in certain localities, and under adverse conditions. When hurt at all it seems to be our damp climate rather than the cold that does it, and if planted in well-drained soil where they can receive a slight protection and be kept comparatively dry during the winter season, there is little fear of their being injured. Such, at least, is my experience in the neighbourhood of London, where the damp atmosphere, fogs, &c., carry off a greater number of this class of plants than the cold. It is not unusual, when duplicates are planted in different situations, to have some killed while others are untouched, and this will be so until we find out the exact positions in our gardens best fitted to the requirements of these plants. Near to the seaside I believe they grow more vigorously than inland, the glaucous species being almost white, and forming round bushy bushes. As pot plants they are well adapted for the balcony, the corridor, and the conservatory

they have a future before them, and have already been used with advantage; the variety in habit and size, as well as the various hues of colour, give them an interesting as well as an ornamental appearance. If cuttings are put in in the autumn they will root freely and make good specimens by the second year. For the rock garden I have found them very useful.

V. LINDBERGANI, is one of the oldest plants in cultivation, having been introduced many years ago, and undergone vast improvements. *Anderssoni*, *kermesina*, *versicolor*, *hamatifida*, *macrocarpa*, &c., either hybrids or improved forms of this species, are largely used in the conservatory and greenhouse, and where space admits of their being planted out they make beautiful specimens in a few years.

V. SALTICOLA, a fine, shiny-leaved shrub, bearing numerous spikes of white flowers, variably, and generally longer than the leaves; *V. parviflora*, a small-flowered, very graceful species. Other allied forms are *V. Kirki*, *speciosa*, *erecta*, &c. Amongst the latest introductions are *V. Lyalli*, *Holkema*, *Gaturovici*, *clathrata*, *venicosa*, *heris*, *monnini*, *elliptica*, *Colensoi*, *implexicaulis*, *pinnatifida*, *sparsiflora*, *Honstii*, &c.

V. TRAVERSI (here figured) is one of the old ones, having been in cultivation many years. It is amongst the hardiest of the shrubby Speedwells, and is certainly one of the most beautiful and useful in a garden. Unless after an unusually severe winter, it never fails to produce freely its pretty white clusters of flowers, which in contrast with the dark shiny leaves make a

New Zealand Speedwell (*Veronica Traversii*).

charming picture. It is an excellent plant for the rockery, where with a little shelter it forms fine bushes full of interest both in summer and winter. Other varieties are *arborescens*, *pinquifolia*, *carneola*, *dissimifolia*. K.

COLD FRAMES.

SINCE the introduction of hot-water pipes cold frames have fallen into disrepute—at least, during the winter months they are still used for sheltering half-hardy plants. I suppose very few of the present-day gardeners would like to try their hand at carrying a lot of bedding plants, such as *Geraniums*, *Lobelias*, *Petunias*, &c., through the winter, much less *Cinerarias*, or any other soft wooded greenhouse plants; yet it is done, even in these advanced days. It is not many years since I knew one of the old school of gardeners who kept all his stock of plants for

some very brilliant bedding out in a few cold frames, and some of the finest, dwarfiest, and cleanest *Cinerarias* I have ever seen were wintered in a cold frame, but it requires a deal of labour, and I question if anything is gained on the score of cost. The plan pursued with the bedding plants was to set the frames in a sheltered position from wind, and where every ray of sunshine could be utilised; the plants were kept fully exposed to the air on all occasions when there was no frost, but directly frost threatened, the lights were shut down close and double mats put over the glass, and in November the sides of the frames were encased in litter at least a foot thick, and after that date a good coating of litter was laid over the mats at night and removed in the morning, and by keeping the plants dry, and every decaying leaf removed, a very large percentage of the plants were safely carried through the winter. J. G. H.

ORCHIDS.

THE DOVE PLANT (PRISTERIA ELATA).

I HAVE by me a number of letters from various persons asking many questions respecting this plant, but in all of them there is the complaint about its not flowering, and I have thought it best to answer all that it may concern in an article upon the species. This is a plant that all may grow in their stoves with a mixed collection of other plants; there need be no fear of its being too hot for it, for this Orchid comes from Panama, when it is subjected always to a great deal of heat. It was called by the early fathers who settled there the *Ri Spiritu Santo*, and hence comes the name of the Holy Ghost-plant, so called from the resemblance of the lower part of the flower to a little white dove. It is a bulb and handsome plant in its habit of growth, making very large bulbs, and bearing large lanceolate, dark-green, plaited leaves, each some 2½ feet long, sometimes more, and erect flower-spikes, which grows from 3 feet to 4 feet high, bearing numbers of its globose, waxy flowers, so that the plant becomes an object of much attraction. Now, for the non-flowering, which my readers complain about. I am somehow led to the conclusion that some of these having invested in a Dove-plant, no sooner get home than they begin to look about and want to see it flower. This is reasonable enough, but they entirely forget that if their plant is not strong enough to bloom it will not do so, and all the wishing for it is not of the least avail. I am quite willing to admit that there are sky-flowering varieties of the Dove-plant as well as of many others. I had one upon one occasion, and it was given me to try and flower. The plant had been bought at the sale of the celebrated collection gathered together by Mrs. Lawrence, of Ealing-park. It had been kept for a few years, and it never produced a flower-spike, although it had larger bulbs than I ever remember to have seen *P. elata* with to this day, and for four years I grew it, treating it just in the same manner that I did my other smaller plant that flowered annually; in fact, it always occupied a place within a yard of it, but never presented the sign of a spike. Hence then, I say, was a striking example of a free-flowering variety and a shy one, and as I could not derive any pleasure from it I sold it in London, and its large growth caused it to realise a good amount, and I hoped with a change of situation it would turn over a new leaf and flower with profusion. From the conduct of this plant it is not right always to say if your specimen is strong enough it will be sure to flower. The plant should be treated as a terrestrial one—that is, not placed above the pot's rim, but rather an inch or two below it. The pots should be well and thoroughly drained, and this covered with a layer of Sphagnum Moss, which does not rot away quickly, and prevents the soil percolating into this material. The best mixture is sound turfy loam in good heart, mixed with peat and chopped Sphagnum Moss, all well incorporated, and put in firmly, the bulbs sitting on the top. Water may be given freely during the growing season to its roots, and a great deal of moisture in the atmosphere, beside which sprinkling overhead from the syringe night and morning before and after the sun has power, for although this plant

enjoys good exposure to the sun and light, a slight shade is necessary just at the very hottest time of the day, for it must be borne in mind that the plants are under glass.

MATT. BRAMBLE.

AN AUTUMN-FLOWERING ORCHID.

CATLEYA SANDERIANA.

"This fine form of *C. gigas*," says "H. H.," "has just opened the first of seven flowers, which it has coming. It has bloomed with me for three years in succession in the month of December, so that it is quite a late flowerer; more especially is this the case after the exceptionally hot summer we have had." Yes, my friend has a very good form of the plant and it is an exceptionally late bloomer, and it should have the name of autumnalis attached to it, which name is very foolishly tacked on to the true *C. labiata* by many amateurs, because the labium named by Lindley was an autumn bloomer; consequently, it does not require to be so pointed out by a specific name being coined and added to it. In the case, however, of *C. gigas*, which may be called a late summer bloomer, a variety which appears year after year in the month of December, what can we do otherwise but call it an autumn-flowering variety? I may add that at the present time I know of some three places round about that have a form of this variety flowering, and only one of these is a good one. I know the flower of "H. H.," he having sent it to me last year, the sepals and petals being broad, and of a rich rosy hue, the large lip being much undulated round the margin, of a deep crimson, shaded with purple, and with a pair of large rich yellow eye-like spots, standing one on each side of the throat. The plant will require careful finishing off after blooming, and it should be kept dry and cool until it commences to grow afresh, when it may be either repotted or resurfaced, and again find its place in the Cattleya-house.

MATT. BRAMBLE.

THE BIRD'S-BEAK ONCIDIUM (O. ORNITHORHYNCHUM).

In reply to "G. J." and others, I must say a few words about this *Oncidium*, which was always a favourite with me, although a small-flowered one, because of its fragrance. In colour it is slightly glaucous, producing a branched arching spike, which is heavily laden with its rosy-lilac blossoms, which are relieved with a rich yellow crest. It blooms through the autumn and winter months, its sweet perfume making the house smell delightfully. The variety *nilum* is a charming plant, having pure-white flowers, relieved only by the yellow crest on the lip, and having the same delightful odour. It still remains a scarce plant, and realises a big price. This is an *Orchid* which thrives best in the cool-house, but just at its flowering season it is all the better for having a few more degrees of heat than it gets there. It should be well drained, and planted in either a pot or hanging-basket; in the latter I think it is most effective. When its flowers open it should be hung lower down to enable the ladies of the establishment to cut some sprays without committing any damage, for the perfume will be sure to cause them to appropriate a piece, and this want should be accommodated as much as possible. For soil use good heavy peat fibre and chopped *Sphagnum Moss*. Water freely when growing, and do not let the plant suffer for water through the winter, but it must be given with greater care at this time.

MATT. BRAMBLE.

IVY-LEAVED PELARGONIUMS.

THESE useful plants may be grown like other *Pelargoniums*, with the support of four dark-green sticks, round which the long shoots are trained, or used as trailers for window-boxes, or even as basket plants, in all of which positions they do well. These *Pelargoniums* are also suitable for window culture, and may be grown to great advantage placed on brackets in the woodwork of a bow-window, from whence they trail downwards, showing their beautiful blossoms to great advantage. An old plant, slightly cut back and repotted in spring, will go on blossoming for *many weeks*, only requiring another shift and the removal of some of the

lengthy sprays to start again later on. They are thus almost continuous flowerers, and they will bloom even in the depth of winter when grown in slight heat with a sunny aspect. The double and semi-double varieties are considered the best, many of the blossoms rivaling in beauty those of the French varieties from which they derive their descent. Those of a magenta tint are not so desirable as the clear rose and carmine shades, which harmonise so much better with the rest. Magenta is a singular colour in this, that no other shade of red or blue looks well with it. Unless a plant with flowers of this tint can be grown alone, it is, therefore, best avoided. Among Ivy-leaved *Pelargoniums* the following will be found the best: *Mme. Crusse* (pale-rose and maroon), *Louis Thibaut* (clear bright rose colour), *Mignon* (a dwarf variety with salmon flowers), *Souvenir de Charles Turner* (brilliant pink and violet), *Beauty of Castle Hill* (salmon, shaded with rose, very fine), *La Rustique* (very double, soft-rose), *Lilyet* (bright-cerise, with large flowers), *Prince of Wales* (shaded-purple), *Murillo* (velvety-purple, with large flowers), *Newton* (fine vermilion-red), *Galilee* (large trusses of bright pink flowers), and *Sarah Bernhardt* (pure-white, with maroon veining). Ivy-leaved *Pelargoniums* are easily propagated by cuttings or slips during the summer, and should be grown on in large plants, repotting them in good ordinary compost as necessary. As the flowers are borne mostly at the terminal points, it is well to cut these back after flowering to induce the side-shoots to break freely. Liquid-manure or soft-water, during their flowering season, will benefit the plants and keep the foliage handsome. Directly the leaves begin to turn of a lighter shade of green, the plants will require repotting or a liberal top-dressing.

R.

OUTDOOR PLANTS.

ADAM'S NEEDLE (YUCCA GLORIOSA).

THIS is a large and imposing *Yucca* (see illustration) of distinct habit and somewhat rigid aspect. Its flower stem is over 7 feet high and much branched, and it bears an immense

Adam's Needle (Yucca gloriosa) in flower.

pyramidal panicle of large flowers almost white. Its numerous leaves are stiff and pointed; it is one of the noblest plants in our gardens, and suitable for almost any position. It grows very much when grown from seed, and this is a

good recommendation, as the greater variety of fine form we have the better. Its chief varieties are *Y. g. longifolia*, *plicata*, *maculata glaucescens*, and *minor*. The soil for it should be a rich deep loam. It is a native of North America. G.

TRANSPLANTING HARDY PLANTS.

If you want hardy plants to show the full beauty of which they are capable, you must not let them stand year after year in one place, for the very obvious reason that they are strong rooting and gross-feeding subjects, and soon exhaust all the available food within their reach. Now, although this can be partially remedied by rich top-dressing, or applications of manure in liquid form, it does not have the same effect that transplanting to fresh soil has. I grow hardy plants for the sake of cut bloom, and grow each kind by itself in beds about 6 feet wide, with alleys between for convenience of cutting the bloom, and certainly in no other way can finer blooms be had. During the past exceptionally dry season we had ample opportunity of observing the difference in growth of plants of the same kinds that had been transplanted on to fresh soil, and there left on ground occupied for one or more years previously. And I need only mention one or two—viz., *Helianthus*, or *Perennial Sunflowers*, and *Michaelmas Daisies* as types of the whole. These transplanted to fresh soil grew away strongly and flowered freely; but those left in old beds could hardly make any headway against the drought, and the flower-stalks were very short, and the individual flowers very small. The following are types of many kinds—viz.:

ANEMONE JAPONICA (Autumn Anemones), white and pink, are strong-rooting subjects that soon exhaust the soil, and should not stand more than two seasons if fine blooms are desired, and spikes to attain 5 feet or 6 feet high.

ACHILLEA PTARMICA, a lovely white flower, very useful for wreaths, blooms nearly the whole summer. The underground roots spread out and make fine clumps, but if left long in one place it dies away altogether.

CHRYSANTHEMUM MAXIMUM, one of the finest of *Marguerite*-like flowers, should be divided and replanted on to fresh soil every year if possible, as there is no comparison between the size of the blooms, even the second year after planting, with those on newly-planted beds.

CARNATIONS require and repay for replanting every year. Not only do they flower more profusely, but the plants die away if allowed to stand long in one place.

HELIANTHUSES (*Sunflowers*) in great variety: are very strong-rooting plants, and soon exhaust the soil. Half-a-dozen clumps on fresh soil will bring more flowers than twelve the number left over two years.

MICHAELMAS DAISIES are such useful plants for cutting that they ought to have good culture. All their wants are supplied if you divide and replant on to fresh soil every alternate year.

FULOXES of herbaceous kinds are very similar in their growth, and need good rich soil to do them justice.

LYNETHUM FLORIBUNDUM is a splendid plant for late autumn blooming, but unless it can get abundance of food for its roots it is of little use. Dig, replant, and feed well.

PINKS, if left more than two years, get long and straggling, and die away in the centre of the clumps. Digged in the autumn, every piece makes a good plant. JAMES GROOM, Gosport.

NOTE.—Hardy Lily-beds.—Your query entails a rather lengthy answer. The best way of all, if you are in a position to do it, is to plant the Lilies amongst shrubs, and it is in this way that one gets such splendid effects in the autumn. *L. auratum* amongst *Rhododendrons*, or *L. speciosum* amongst *Kalmias*, create delightful pictures. I remember once seeing the pure-white *L. candidum* planted against the Purple Beech, and the contrast was most effective. Well, first, as to the soil and position for Lilies, as they do not all require the same treatment, some preferring heavy soil, others peat. As regards position, amongst shrubs is unquestionably the best, and the very best kinds, varieties of *L. elegans*,

sometimes called *L. thurricum*, may be planted amongst Heaths. If one wishes to make a Lily-bed one must choose aright, getting those together that prefer loam and those peat. The Martagon Lily will not thrive in peat, but in loam, but the Tiger Lily is not particular, succeeding in almost any garden soil. The beautiful bull Lily (*L. testaceum*) requires humus, also *L. pardalinum*, the Scarlet Martagon, or Turk's Cap Lily (*L. chalcedonicum*) the Orange Lily (*L. croceum*), and *L. davuricum*. It is a pity that *L. croceum* is not more seen, as it is a fine old kind, and one of the easiest of all to grow. *L. tigrinum splendens* is a noble flower, deep-crimson with richer coloured spots, very free, and vigorous. The white *L. candidum* is often one of the most refractory of Lilies, from the experience of many people, imported bulbs flower well the first season, but afterward, as a rule, fungal disease attacks stem and leaves, and both dry up and wither before the flowers open. This, I think, is a general experience, but the finest mass of this Lily I have ever seen was in a sloping garden at Bath, hot, and apparently very dry. This mass I have never seen equalled. Another good Lily is *L. longiflorum*, the flowers very large and ivory-white. It is usually grown in pots, but well worth planting in the garden, and replanted every third year. As regards peat-loving Lilies, *L. auratum* must be first mentioned, and one gets a splendid mass of colour if the bulbs are good. Such fine importations come over from Japan that there is no reason for getting poor stuff. Two charming little Japanese Lilies are the scarlet *L. concolor* and the yellow *L. Coridion*, the flowers very neat and showy. *L. elegans* and *L. superbum* may be also included. All the above kinds are cheap, and you can plant single bulbs, putting them fairly close together to get a rich effect. Humus is neither necessary nor desirable for Lilies; it is hurtful to them, except *L. auratum*, and in this case need not be given. *L. superbum* is a splendid species, very tall, the stems rising to over a height of 7 feet, and bearing flowers of intense and varied colours. By planting the foregoing you will get quite a succession of bloom, *L. candidum* being one of the first to open, finishing with *L. speciosum* and *L. tigrinum* late in the year, usually about October, although in some seasons, as last, for instance, they were much earlier than usual. You might plant the bulbs named above the Lilies, but be very careful not to disturb the bulbs. I should prefer to grow them in clumps rather than apart. A mixture of Lilies in a bed would not be very enjoyable, as they differ so greatly in height, aspect, and the colour of the flowers. Plant them in clumps in the border, keeping them distinct, if you have no struts to plant them amongst as suggested.—V. C.

5961.—**Pampas Grass.**—Do not cut the Pampas Grass down, trim off the dead leaves for the sake of tidiness, but nothing more. If the plant does not flourish as well as could be wished, remove the surface soil 3 inches deep for 3 feet all round, and replace with better, giving it a good dressing of partly-decayed manure, at the same time forking it in amongst the surface roots. Should the weather be dry next summer give the roots several good soakings of water to encourage a free and vigorous growth.—S. P.

The fact that you are in doubt whether the Pampas Grass should be cut down or not shows that you know more about its proper treatment than your advisers. It should not be cut down, as the old foliage affords some protection against severe frost and cold wind. In April the tops of the old leaves may be shortened back, and nothing more should be done to it. In the case of old plants it is a good thing to clear out the centre once a year, as dead leaves and other matter accumulate at that point and kohl the moisture, and then very hard frost has more effect on it.—J. C. C.

In some districts the Pampas Grass suffers during severe winter, and if cut back now and cold weather comes shortly the plants might die. It is much safer to leave the cutting back till May. All the old discoloured leaves may be cut away, but I should hesitate about cutting down close to the ground.—E. R.

5967.—**Bees and Carnations.**—Though bees may injure certain flowers, I have not found them specially injurious to Roses and Carnations.—E. H.

WOODLAND FLOWERS.

LARGE WINTER-GREEN (PYROLA ROTUNDFOLIA). There is a charm about the modest beauty of some wood plants that cannot be equalled by the most brilliant of our own border flowers, and their wonderful harmony with the senti-

Large Winter Green (*Pyrola rotundifolia*).

ment of poetical mystery that reigns in woodlands cannot fail to impress every true lover of Nature. Such gems as the little Twin-flower (*Linnaea Tricotalis*, and the Winter-green might escape notice in the full light of an open place, but in the half light of their shady world, set in Moss, and amid the rich, quiet colourings of forest-earth their little bells and stars have the value of precious jewels. These woodland plants also do well on the shady side of a rock border. J.

Stock "Maive Beauty."—There is no more distinct and beautiful variety among the Ten-week Stocks than this. In habit of growth it is a model of what a Stock should be; compact, yet free branching, flowering freely, and throwing up a centre and several side spikes of charming double flowers. In colour it is soft-pink, deeply flushed with mauve; it is very humble, and there are but few single varieties among it, and it is this characteristic which tends to make the seed so very scarce. It belongs to what is termed the pyramidal Ten-week Stocks. It is a type of Stock well adapted for flowering in pots, because of its compact, handsome growth. The seed can be sown early in spring for summer flowering, or it can be treated as intermediate, sown in July and August for blooming in pots in the following spring. Mr. Samuel Barlow, of Manchester, used to make lawn beds of this and a line crimson-flowered Ten-week of a good habit, which was known locally as Dyon's Stock—sowing the seeds in June and July, growing on the plants in pots all the winter, whitening them two or three times to get them into size, and then planting them out in April and May, when they bloom grandly and are most effective.—D.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful rare flowers and good fruits and vegetables for illustration. The drawings, as made up, are engraved in the best manner, and will appear in due column in *Gardening Illustrated*.

ROSES.

ROSES IN AN UNHEATED HOUSE.

Or all climbers for unheated houses, I think the Rose is the most suitable. When we bear in mind how well they grow upon a wall or fence in the open, it is evident that the further protection of a rod-house may be used to great advantage. There are two points which should be borne in mind and acted upon—careful ventilation, so as to secure a more uniform temperature, and to keep the plants as backward as possible during January and the early part of February. Where other subjects are grown they will, of course, be those which need somewhat the same treatment, seeing it would never do to cultivate any which could not stand a few degrees of frost at this period. I may remark here that my experience proves plants will stand a few degrees more frost when under cover than the same plants would be able to battle against in the open air. In a cold-house of this description we get the full benefit of early spring sun free from the checking influences of cold winds and night air, and things come on very rapidly—too much so, in fact, unless checked as much as possible during the early part of the year. We must not forget that if we encourage early growth we have not sufficient means of keeping a spell of cold weather from them, and such often occurs during March. But to get to our subject more closely, all of the Roses should be pruned at once, very little of this being necessary with climbers, if the instructions about

SUMMER PRUNING have been carried out. We must remember that, being under cover, the sap will rise more early than if exposed, and we also have the means of keeping cold weather from the young growth when once we have allowed it to start freely. It is this latter fact which is the cause of such grand Roses being produced in cool-houses. The frost which cripples the early growth of those out-of-doors is not sufficiently severe to affect that under glass, provided the latter have not been allowed to start prematurely. Reckoning we get a good crop of Roses in the open border by the end of June, we shall have a crop of bloom in April under glass.

VENTILATION is a somewhat difficult matter, because we so often have a bright sun, which is, so far as outdoor Roses are concerned, tempered by a keen wind. The action of sun upon the glass speedily raises the temperature, and we cannot give ventilation to reduce this unless there are ventilators provided upon all sides. Always give it upon the sheltered side, and avoid lowering the temperature too suddenly. This is very injurious, and conduces to serious attacks of mildew more than any other one thing. Upon such days give a little air early in the morning, gradually increasing it as the sun gains in power. The same tactics should be adopted when closing the house. As the plants begin to grow freely a moister atmosphere will be beneficial. This can be secured by damping the walks and walls during the afternoon and early in the day. Do not damp down too freely at night. Keeping the syringe going upon all bright mornings, especially if a few aphids are about, has much to do towards success. As the sun gets more powerful, it will be necessary to afford a slight wash of some kind, so as to avoid the burning propensities which often injure the young foliage. Let this be weak, because Roses enjoy plenty of light. I use a weak wash of whitening and milk. This keeps us well, and yet is not too tenacious, generally being washed off by the time we need the glass clear again. More air will be necessary as summer advances, and the plants should receive a generous treatment, so as to secure good wood for the following season.

MARCELA NIEL and kindred varieties only afford us one full crop; but the dwarfier kinds, such as General Jacquemont, Catherine Mermet, and Madame Falcot will bloom freely all the early summer. After this they should be stood out-of-doors to ripen their wood. When training the climbers see that the wood is at least a foot away from the glass, or the young growths will soon be against it and be much more liable to injury from frost. P. U.

Rose "Baroness Rothschild."—This is by no means a suitable variety to grow in a cold-house upon its own roots; how, for, it

is cultivating to do so. I would advise your existing strong growth in a natural manner, and so encourage a stout shoot from the bottom. This can then be disbanded and the remaining growth cut away. I saw some plants this season which had made growth about 4 feet long, and these could easily have been forced into standards; but, as I remarked earlier, Baroness Rothschild is a most unsuitable variety, as a rule, and I would not attempt it.—P. U.

5083.—**Ross in a greenhouse.**—“Plumbago” has got in the plant of this, and provided it has been growing in a pot all the past summer—has, in fact, made the shoot he mentions in a pot—and has not had its roots seriously disturbed, it will undoubtedly bloom well and please. Do not prune it, except to remove a very small portion off of the end of its main stem. When it has flowered you may cut it back and grow on again as strongly as possible.—P. U.

5084.—**Soil for Roses, &c.**—The application of a dressing of rye for the light soil is the best thing you could do for it, and your intended way of treating it is quite right; but for the future do not dig amongst your Roses more than 3 inches in depth, and that only once a year in the winter. Do not apply any manure to the surface until the spring, and no liquid manure until you see signs of young growth being made. Manure laid on in the autumn or early winter has all its goodness washed down below the roots. When the under stratum is composed of gravel give a thick mulch of half-rotten manure after the Roses are pruned in the spring, by all means, and manure-water after the flower-buds are formed.—J. C. C.

I do not like the idea of making a soil still by using clay as a surface dressing. You would have been much wiser to mix it in previous to planting. It is at the lower part of your soil where the clay would have been most valuable, and when mixed with a gravelly sub-soil and generously manured, might have been of service. A little thought will show you it is difficult to fork it in deep enough to be of any practical use, as you would be disturbing the roots. I do not like disturbing the plants after a few weeks in their fresh quarters, especially as they are mulched and protected, but it might be a good plan to lift them, dig the whole over again, and re-plant. If done expeditiously there would be no harm, but it seems such a pity to move them.—P. U.

5082.—**Pot-Rosess.**—You have certainly kept the house too close, or in such an aspect the Roses would not be in the condition you describe. You must ventilate the house more, and over a longer time during the day. It was a mistake to cut in the small plants with a view to check growth. With regard to the plant of *Maréchal Niel*, you must have patience with it. If it does not choose to grow long enough for training, no sort of pruning or coning will make it. It was similar behaviour to this of some plants a few years ago that made some people think there were two varieties of it—a climber and a non-climber; but that has been proved to be wrong. The *Maréchal* is a persistent and disappointing Rose sometimes, and your case is not worse than many more that have come under my notice.—J. C. C.

I have not much doubt regarding the cause of your Roses being in the state you name. You probably have several other subjects in the house, and have been keeping it too warm and close during the latter part of September onwards—at least, for Roses in an unheated house. The plants should have been out-of-doors during the autumn, and only housed now as a protection from severe frost. You had better keep them inured to air and light as much as they can bear, and then prune early in January. The house you describe is suitable for Roses, but I am afraid you have overdone them too early, and will now be unable to keep frost from them during the remainder of winter. The *Maréchal Niel* will probably produce a strong shoot during the coming season.—P. U.

5068.—**Rose-hips, &c.**—Place the hips in sand until spring; keep the sand moist, but not wet. In the spring (*Maréchal*) rub the whole through a sieve in order to break up the hips, and then sow sand and seeds in shallow drills upon a prepared soil of light loam, and so on. As you probably do not need many stocks it

will be better to sow in a box or pans. Place this in a pit or frame, keep dark for a time, until the seedlings show, then admit light. They had better remain in the box two summers. You must keep a sharp look-out against birds, mice, &c., while the seeds are germinating, and against a species of land-flea when they are sprouting freely. I believe *Colvillei nba* and “The Bride” *Glabolus* to be synonymous. They increase very readily from offsets, much more so than any other *Glabolus*.—P. U.

Place the *Rose-hips* in sand now and sow in February. The *Glabolus* will increase in the usual way such hips do; but to work on a stock quick save seeds and sow in drills in spring.—E. H.

5065.—**Baking for button-hole Roses.**—You inquire for a good plant suitable for the above purpose. The *Maiden-hair Fern* you have already tried, and failed. What more can be needed than *Rose foliage*? The *Fern* you name is altogether out of taste. If you must have *Fern*, choose the *Davallia bullata* or some similar kind. I like the *Rose foliage* best, and nothing can be more beautiful or more in keeping than this. When the pink and green shoots are made up with a clean *Rose-leaf* they are perfection. The next foliage in my estimation is that of *Prunus pissardi*; this has a slight resemblance to the deep-coloured shoots of *Rose* growth. Grow a few of the *Pairy* *Roses*, and use their growths if you do not like to cut that of the plant the button-hole is culled from.—P. U.

No greenery is more suitable than their own leaves, adding to each a spray of *Asparagus plumosus*, which will succeed in a greenhouse, provided it is planted in a compost mainly of peat and leaf-soil. If during the winter months *Rose-leaves* are difficult to obtain, small *Ivy-leaves* are a good substitute; they are lasting and easily made up by the aid of thin bonquet-wire. Those that are coloured from the effects of the weather, such as are found growing against trees, are preferable to green ones, as they contrast so beautifully with the various tints of the *Roses*. If these are objected to, *Chloisyn ternata* might be grown easily in a greenhouse for the purpose.—S. P.

Pruning the *Maiden-hair*, a small frond of the blue *Maiden-hair* *Spleenwort* (*Asplenium Adiantum-nigrum*). This, which is really the same thing as the “*Fern*” of the florists, is a hardy British species, and may be grown easily in any cool, moist, and shady spot, or in a cold frame. A tiny bit of *Adiantum cucullatum* or of *Asparagus plumosus* as well is, however, an improvement. Another plant of which the leaves are very useful for this purpose is the old *Oak-leaved* or *Pheasant's-foot* *Polygonum*.—B. C. R.

5077.—**Pruning a pot Rose.**—If your *Rose* is large enough to require pruning, now is the time to do it; but to tell you how to do it without knowing what sort of *Rose* it is, and how large, I cannot. As a rule, amateurs prune too much, especially when they want early flowers. If you can send more particulars about the age and size of the *Maréchal Niel* I will gladly help you, but with such scant particulars it is impossible so advise you in a way that would be satisfactory. I know plenty of plants of this *Rose* that look so unhappy that if I was asked to advise about them I should say cut them down to within 1 foot of the soil.—J. C. C.

As stated in GARDENING, on Nov. 25th, pot *Roses* should be pruned now. The style and amount of pruning depends entirely upon the variety you possess, and, unfortunately, you do not say the name of the first in your query. I will suppose it to be one of the ordinary growers; in that case, you may cut back to within 4 inches to 6 inches of where each shoot started from last year, entirely removing the weakly shoots. The *Maréchal Niel* will require a different treatment, as this grand *Rose* blooms most profusely from the long maiden growths of the previous summer, therefore the sole object in pruning is to leave as much of this growth as possible and remove the remainder.—P. U.

5064.—**Tea Rosses for button-holes.**—I find that taste differs a good deal in the choice of *Roses* for button-holes. Some people like large flowers and others small ones. William Allan Richardson, which, by the bye, is not a Tea, I find to be a great favourite. Not only on account of its colour—deep orange; but

because the half-open buds are about the right size, and when a single bud is not large enough two or three can be used. *Ma Capucine* (*Teal* and *Perle d'Or* (*Miniature*) are pretty much the same colour and exceedingly pretty. My next favourite for this purpose is *Colsete*, which appears to be as hardy as the *Dog Rose*, and if given good soil grows freely, and produces a large number of exquisitely formed fragrant flowers, which when in a half-open state are pleasing beyond description. *Niphelos* (white) is not too large for some people. Others suitable are: *Anna Ollivier*, *Marie Van Bontte*, *Mme. Lambert*, *Catherine Mermet*, *Devonensis*, *Luciole*, *Safrano*, and *Grace Darling*.—J. C. C.

The following twelve *Roses* are as likely to do well with you as any I am acquainted with, but in smoky, manufacturing town is not an ideal locality for *Roses*: *Honore* (pink), *Safrano* (half-orange), *Mme. Fahnst* (apricot), *Sunset* (apricot and orange), *Isabella Sprunt* (pale-yellow), *Perle de Jurlins* (deep-yellow), *Niphelos* (white), *Souvenir de Thérèse* (pale terracotta), *Sigolun* (fawn), *Mme. Hoste* (leaved straw), *Anna Ollivier* (peach and buff), *Mme. Cusin* (deep-rose and violet). All of these are reliable and produce a large number of neatly shaped buds.—P. U.

If you wish for dark-coloured *Roses* you cannot do better than select a *General Jacqueminot*, *Prince Camille de Rohan*, or *Charles Lefebvre*, which are all good button-hole flowers. Personally, I much appreciate these darkly-coloured, richly-fragrant varieties, although the *Tears* and *Nisettes* are more used for this purpose. The following are good *Tears*: *Luciole* (carmine-rose, suffused with yellow), *Ma Capucine* (one of the most popular of all, the flowers copper-yellow in colour), *Mme. Chelone Guimissen* (yellow), *Mme. Fahnst* (apricot, a delightful bud), *Mme. Hoste* (pale-yellow), the well-known *Maréchal Niel*, *Niphelos* (white), and *Safrano* (apricot, shaded buff). Of the *Nisette* *Roses* *L'Éclair* is one of the best, the flowers coppery-red in colour; a very distinct and beautiful kind for button-holes. Their flowers must be hunched together, as it is a small-flowered *Rose*.—J. C. C.

5087.—**Pruning dwarf Rosess.**—I will answer the latter part of your query first, as you should prune the plants in the unheated greenhouse at once. It may be well to remind you that none of the climbing varieties should be pruned hard—in fact, their long growths must be left entire. The plants in the open ground should be left until March or early in April. Much depends upon the season; but there will probably be a short general article upon this subject in due course.—P. U.

Answering the latter part of your question first, you may prune the *Tea* *Roses* in the house at once. Knowing your locality pretty well, I should not hesitate to prune dwarf *Roses* in the open ground in the second week in March.—J. C. C.

5054.—**Side of Climatic Jackmani, &c.**—You had better keep the seeds in a cool, dry place until next March, and then sow them in pots and raise the plants in a greenhouse. Both kinds of *Clematis* may be raised in this way, but you must have patience, as sometimes the young plants are many weeks before they come through the soil. Apple and Pear pips may be raised in the same way if you have only a few of them. When there is any quantity they are sown in the open ground in the spring, and transplanted the next year.—J. C. C.

4874.—**Definition of loam.**—The word *loam* generally implies a soil that is easily worked at any season, being sufficiently retentive yet not so much so as to hold water. *Maiden loam* is a term used often among gardeners to describe the fat earth forming the top spit of a pasture ground, and is used by them for different composts. That with a yellowish-brown colour is most preferred. Sandy loams are the easiest worked, and yield the earliest produce. Chalky loams, if the chalk does not abound too much, are early and fertile; in fact, no soil will continue good without some calcareous matter in it. Clayey loams are bad to work either in wet or dry weather, being wet and sticky in one case, and dry and cracking in the other. Fine late crops, however, are produced from such soils, especially when the surface is kept well and to prevent cracking in dry weather.—J. C. FERRIS, *Hartford*.

FUCHSIAS IN BASKETS AND ON ARCHES.

THE end of March and in April are good times to put young plants of Fuchsias into baskets, in order to obtain a good display late in summer and throughout the autumn. Varieties of slender habit are best adapted for the purpose, and if the shoots be kept persistently stopped the plants will form dense bushes, which will cover the bottoms and sides of the baskets, and, when suspended from the roof of a greenhouse or conservatory laden with them will form striking objects. The flowers, indeed, are shown off to greater advantage in this way than when the plants are grown in pots and trained in a pyramidal section. Good rich loam, plenty of water, and timely attention to stopping the shoots so as to obtain a dense procerbus habit at first are all the plants require to bring them to a high state of perfection (see illustration). The Fuchsia is also admirably adapted for training over an arch in any glass-house; each branch is then brought by the weight of its blossoms to display its beauty in the most effective way. No plants are more effective on arches than Fuchsias properly managed. By stopping the shoots at different heights, and training them over with some care, the entire arch may be wreathed all round with almost an equal amount of beauty. It is surprising that the Fuchsia is so seldom used for this purpose. A glass warrior arched over with Fuchsias would prove a charming addition to many gardens, costing little to plant and less to cultivate. B.

OUR READERS' ILLUSTRATIONS: FUCHSIA "DELICIA" IN A BASKET. FORWARDED FOR GARDENING ILLUSTRATED FROM A PHOTOGRAPH SENT BY MR. E. GODERHORN, HÖBBECHT HALL, NORWICH.

are Almira, Annie Douglas, Agnes Chambers, Aurora, Chrysolora, Countess of Jersey, Lillian, Mrs. Herwood, Mrs. Walford, Mrs. Whitbourn, Mrs. Robert Sydenham (the best yellow), Remembrance, and Undine. The best self-coloured Carnations are Abigail (carmine rose), Aline Newman (deep-red), Lady Gwendoline (rose), Mrs. Louise Jameson (rosy-red), Niphetos (white), Oriflamme (scarlet), King of Crimson (deep-crimson), Snowdon (white), Duchess of Teck (deep-rose), Germania (deep-yellow), King of Yellows (pale-yellow), King of Scarlets, Mrs. Muir (white), Mrs. Reynolds Hole (apricot), The Governor (blush), Ruby (bright-rose), Mrs. Apsley Smith (scarlet), Ketton Rose, White Lady (pure-white), Mrs. Fred (the best formed pure-white). Fancy varieties: A few good ones are Victory, Terra-cotta, Old Coin, Lord Rendlesham, Stalworth Bail, Madame Van Blatte, Ala Wallington. The above have yellow or terra-cotta coloured grounds variously flaked and spotted. -J. D. E.

selection would comprise Countess of Paris, a robust, free-growing kind; the flowers large, beautifully formed, and blush, almost white, whilst they are produced freely on tall, stout stems. Germania is the best of yellow, but I recommend more of this class, as the plants grow very weakly. They are most conspicuous in this respect. Hornee is a good kind, the flowers, unfortunately, rather given to splitting, but they are brilliant scarlet in colour, full, and very bright. The habit of growth is vigorous, and it is not necessary to have a profusion of sticks. Ketton Rose, rose, very free; Mrs. Frank Watts, pure white, a good grower; Mrs. Reynolds Hole, apricot colour, but there is an improvement in this not yet in the trade, with flowers that do not split so much as those of this variety; Alice Ayres, pure-white, with stripes of carmine on the petals; Mary Morris, rose-pink; Napoleon III., rich scarlet, a very brightly-coloured kind; Ruby, salmon-pink, the flowers fringed, a delightful variety where cut

loam is desired, and, of course, the Old Crimson and White Chive Carnations. These will form the foundation of a good collection, and others may be added as they appear and are worth consideration. The great thing is to get varieties with flowers that do not split. Those that burst are very objectionable, flinging their petals about in a way that is neither beautiful nor interesting. Very few Carnations, indeed, are free from this great blemish, and raisers should aim at getting kinds that do not in the slightest split their anthers. Very important also is a good stout stem to support the flower, and also ample "grass," as it is called, which, however, simply signifies growth. The flowers should also be of good decided colours, not objectionable shades of poor effect in the garden. -C. T.

3091. - *Lilium auratum*, &c.—Only for the first year have I found English-grown bulbs to be better than imported ones; after that they decline in strength, like the others, and disappear altogether. I do not think it wise to plant in the open at this time of year imported roots; you had better continue your previous treatment. I cannot, however, advise you to invest largely in either of the Lilies you mention for open-air culture until you have tried them on a small scale for three or four years,

as I know to my cost that there are some soils in which they will not thrive, not even when the positions are prepared for them with apparently the most suitable compost. -J. C. C.

3090. - Treatment of Cape bulbs. - *Crimm asiaticum* is not considered to be an aquatic, and you surprise me when you say it has done so well in your pond. I should continue the same treatment, especially as you have the young ones to depend on. With regard to the latter, they had better be allowed to remain in the pots they now occupy to get stronger; the beginning of March will be soon enough to give them more room. Are you aware that *Crimm asiaticum* is called the Poison-bull, which appears to refer to its possessing some poisonous character? I do not wish to alarm you, but it is as well that you should know this. -J. C. C.

3085. - Name of a Lily.—The Lily not unlike *L. auratum* with crimson down the centre of each petal was probably *L. auratum* var. *rubra vittatum*; that is the character of this variety. There are several varieties of *L. auratum* more or less of this colour. -J. D. E.
The Lily is probably *Lilium auratum*. -E. H.

5957. - Best Carnations.—A complete list of the best Carnations in all the classes would comprise a very large number of varieties; and even in garden catalogues the colours are not described. As regards the flakes, bizarres, and Picotees, the class to which they belong describes the colours. For instances: Scarlet bizarres have scarlet and maroon on a white ground, and the best in this class are Edward Adams, Fred, Joseph Crossland, Robert Houlgrave, Robert Lord, and Squire Potts. Crimson bizarres have a crimson and purple stripe or flake, and the best are Phoebe, Edward Rowan, Harrison Wier, Virgil, John Harland, and William Wardell. The best pink and purple bizarres are Harmony, Autoerat, Sarah Payne, Niobe, William Skirving, and Mrs. Gorton. The best purple flakes, flowers are flaked or striped purple on a white ground; Charles Herwood, James Douglas, Florence Nightingale, Mayor of Nottingham, Squire Whitbourn, and Mrs. Douglas (Dixon). Scarlet flakes: Alismoni, Cannell Junior, Miss Constance Grahame, Gregorius, Sportsman, Mutador. Rose flakes: John Keet, Lady Mary Currie, Rob Roy, Thalia, Tim Bobbin, and Rosa Mundi. Picotees are classed as red, purple, and rose, or scarlet-edged, and the best of the red-edged varieties are Brunette, Gaymède, J. B. Bryant, John Smith, Mrs. Gorton, Princess of Wales, Violet Douglas, and Thomas William. The best purple-edged are Ann Lord, Calypso, Clara Penson, Jessie, Her Majesty, Mrs. Chancellor, Muriel, Nymph, Silvia, and Zerlina. Of rose and scarlet-edged varieties the best are Constance Heron, Corielis, Ethel, Liddington's Favourite, Mrs. Payne, Miss Lee, Mrs. Distin, and Mrs. Royal Visit. The best yellow ground Picotees

— The following will be found a good selection of the best Carnations. The first-named dozen have been growing and flowering freely in the open. The last-named six are good for winter flowering. Ruby Castle (clear soft salmon-pink), The Governor (blush-white), Mrs. Reynolds Hole (salmon-apricot, shaded amber), Lord Salisbury (pure white), Alice Ayres (pure-white, centre petals delicately-marked crimson), Daniel Delworth (clear-purple), Mary Morris (rose-pink), Tom Power (scarlet-bizarre), James Douglas (purple-flake), Joseph Lakin (crimson-bizarre), Robert Council (scarlet-flake), Tim Bobbin (rose-flake), Lizzie McGowan (pure-white, deliciously sweet, free-flowering), Pride of Penshurst (yellow), Germania (cayury-yellow), Winter Cheer (scarlet, shaded crimson), Saccharissa (primrose, striped and edged soft-pink), Miss Joliffe (soft-pink). -S. P.
— There is now a good list of Carnations, and I advise you to get the best self varieties. There are a number of very beautiful French kinds, of which are not, I believe, in the trade, although I hope they soon will be. A very good

with smooth leaves that can be readily cleansed in this way should be preferred, and will thrive best. Again, the plants ought always to be either removed from the room, or at any rate be covered with a newspaper or light cloth while the room is being swept and dusted, and they should also be removed, or at least stood down on the floor as soon as the gas is lit in the evening. The less gas is burnt in the room the better, and the plants will be found to thrive vastly better if only oil-lamps or the electric light are employed. Thorough draughts are very injurious to plants of all kinds; hence, whenever the window is opened it should be at the top, not the bottom. On frosty nights a double thickness of newspaper laid over the plants and between them and the glass will render them comparatively safe; but if the frost is very severe they ought to be removed farther in the room, placing them by preference on a table or stand, and not on the floor, where there is generally a cold draught, and hard frost often strikes through the flooring first. In the spring and early summer, while in active growth, most plants are benefited by being occasionally, even daily, lightly sprinkled overhead with a very fine-rosed can, small syringe, or even a brush dipped in water will do. As regards watering, the best general rule is to give none till the soil is nearly dry and the pot rings hollow when rapped, then give a thorough supply; but when in full growth and bloom most things may be kept almost constantly moist at the root, though with a few exceptions, such as *Spiræas*, *Arum Lilies*, and the *Umbrella-Grass*, or *Cyperus*, plants ought never to stand in saucers of water for more than a few minutes. When at rest in the winter keep everything comparatively dry, but evergreen subjects need more moisture even then than those of a deciduous nature. A little manurial stimulant should be given occasionally, but only while plants are in full growth and bloom, and not for some time after being repotted. Just enough good guano to colour the water, or a little Albert's manure once a fortnight is a good thing, or a pinch of sulphate of ammonia may be added to the water (½ oz. to the gallon is the right strength) every three weeks during the summer: for Ferns and foliage plants nitrate of soda is better. Rain-water is preferable to that from the mains, and if slightly sooty so much the better. Insects must be kept down by means of a little Tobacco-powder, by fumigation, only dipping in weak Tobacco-water or in an infusion of Quassia-chips with a little soft-soap. Some of the best plants for a town window are the ordinary "Geraniums" (white, scarlet, pink, &c.), and even the large-flowered *Pelargoniums* (the market and "French" kinds are the best) may be managed with a little extra care, *Fuchsias* of vigorous growth, *White Marguerites*, *Petunias*, single and double, ordinary *Yellow and Brown Callarias*, *Arum* (or *Calla*), *Scarboro'*, *lanatifolium*, and other *Lilies*, *Begonias*, especially *B. Weltoniensis*, and some of the older, free-flowering kinds, *Musk*, *Persian Cyclamen*, *Streptocarpus* hybrids, *Chrysanthemums* (dwarf), *Plumbago capensis*, *Chinese* and other *Primulas*, and a few others. *Roman* and other *Hyacinths*, *Tulips*, and other bulbs also thrive admirably. Foliage plants are even more easily managed, the best being the *Aspidistra*, common green-leaved *Dracenas*, *India-rubber-plants*, *Arancaria excelsa*, *Myrtles*, *Cumelias*, *Orange* and *Lemon-plants* (easily raised from seed), and such Ferns as *Pteris cretica*, *P. serrulata*, *P. tremula*, *Asplenium bulbiferum*, &c.—B. C. R.

The best plants for a window in London are the *Aspidistra lurida variegata*, the finest of all, *Arancaria excelsa*, very pleasing when small, *Pteris cretica albo-lineata*, *India-rubber-plant*; and such Palms as *Corypha australis*, *Rhapis flabelliformis*, and the handsome *Cyperus alternifolius*, must not be forgotten, this succeeding well in a moist position. It will be more necessary to take care the leaves of those plants that are leathery and smooth on the surface must be kept well sponged two or three times a week with tepid water, otherwise they quickly get coated with dust and dirt. Give water only when required, and do not let it stand in the saucers. Between window plants in towns and those in country there is practically no other necessity for different treatment than sponging the leaves more often.

INDOOR PLANTS.

GREENHOUSE DAISIES.

There are several plants with Daisy-like flowers useful for the greenhouse, and amongst the best are the *Marguerites* (*Chrysanthemum frutescens*), and I do not think that I overestimate the merits of these plants when I say that everyone leaving space for a score of plants should include them in their collection. The yellow variety *Etoile d'Or* especially is one of the few things that bloom in winter in a house which is only heated to keep out frost, and for this reason it should be valued by those who, desiring flowers in winter, have no warm-house in which to bring them along. There is scarcely a plant in cultivation that can equal this *Marguerite* in continuity of bloom; in some months will flower uninterruptedly during nine months of the year, but this is, however, more than should be expected of them. Plants intended for winter blooming ought not to flower in summer, but should have the buds picked off until the end of September, after which time they may be allowed to develop, and will open from the beginning of October onwards through the winter and spring. Cuttings strike with the greatest freedom either in warmth in early spring or later on in a cool-house or frame, and, growing freely, will come into 4½-inch pots early in autumn. In the form of bushy specimens, clothed with healthy foliage and full of bloom, this *Paris Daisy* is very attractive, but its great value lies in the fact of the flowers being so admirably suited for cutting. They are symmetrical in form, and have long, slender, but strong foot-stalks. Those who need plenty of cut flowers should grow this plant in quantity, as if kept in a constant temperature of from 50 degs. to 55 degs., the beautiful clear soft yellow blooms will be continuously and freely produced all through the duller months of the year. Other beautiful Daisy-flowered cool greenhouse plants are the *Aretoti*, of which one of the best is here figured (*A. asperula arborescens*). Other good kinds are *A. aureola*, *A. grandiflora*, a very fine kind, *A. reptans*, and *A. speciosum*. All the species thrive well in a compost of loam and leaf-soil, and they may be easily propagated by cuttings at almost any time of the year. These cuttings should be put in in pots of sandy soil and placed in a gentle warmth. They must be kept moderately dry or they will damp off. In addition to their great value as cool greenhouse plants they thrive well out-

A greenhouse Daisy (*Aretotis asperula arborescens*).

of doors during the summer months in sunny, dry positions.

AGATHA CELESTIS has a delightful Daisy-like blue flower, most useful for cutting, for which purpose it is largely grown for Covent-garden Market. There is also a pretty variegated form of it. It is easily propagated by cuttings in spring or autumn in slight heat. It may also be raised from seeds. It is also useful as a border plant. Of course, in this short selection of Greenhouse Daisies the great merits of the

many single *Chrysanthemums* must not be overlooked, and almost any nurseryman's catalogue will furnish a good list of the best kinds. B.

FORCING DAFFODILS.

These gorgeous flowering bulb naturally blossom at a very early period of the year—in fact, they are generally known as Lent Lilies, and the season of Lent always brings some very cold weather, for no matter how mild, or how severe the winter may have been, the early spring brings cold, cutting winds and sharp frost, and it is no uncommon thing to find the blooms of the *Daffodils* bending down as if killed by cruel frost; but with the warm rays of the spring sunshine they soon recover, and stand erect and gorgeous as ever; but if protected by a glass roof, a few pots or boxes of *Daffodils* are very effective ornaments to the conservatory or other glass-houses, and anyone having some good established clumps in the open ground may with very little trouble have them in perfection by lifting the clumps and dropping them into pots, filling around them with rich soil, and giving a good watering to settle the soil firmly about them. Set them in a cold-house or frame until the roots are well established, then remove to a little gentle warmth, keeping them close up to the glass, and they will soon expand a fine lot of bloom. Pots about 7 inches in diameter are very useful for decorations, and a good clump of roots will give at least twenty large heads of bloom, and prove quite as effective as many of the most expensive bulbs in cultivation. After the bloom fades gradually harden off, and replant in the open air again; they will be little the worse for their short term of pot culture.—J. G., *Hants*.

CINERARIAS.

A FEW amateurs grow these remarkably well, while others only succeed in getting puny plants, much infested with aphid and mildew. Unfortunately they are much subject to the first of these pests; but if kept clean at the commencement it is much easier to grow them satisfactorily. It is very annoying, not to say prejudicial to other occupants, when the dozen or so *Cinerarias* which most amateurs like to have for early-spring blooming are so susceptible to attacks from greenfly. Probably only one or two subjects need fumigation, but if this is not attended to in time many others are soon troubled with the aphid. In this respect the amateur has a much more difficult task than professional growers, because his house of mixed subjects requires various treatment. One does not care to fumigate the whole house for the sake of a few plants only, and the little delay caused by this frequently has disastrous effects. Instead of fumigation prepare a little insecticide exactly as if you were going to use it for syringing purposes. Let this be in a vessel sufficiently deep to allow of the plant being dipped into it. Before dipping the plant see that all loose soil is removed from the surface, or this will make the underpart of the leaves dirty. If taken in time the unpleasantness and expense of fumigation may be avoided to a great extent, and the same solution will serve for dipping into several times, if allowed to stand in the house long enough to become of the same temperature. After dipping several plants let the solution be strained through a piece of fine muslin, when it will do very well for syringing any plants which may require it. These remarks about dipping are equally applicable to many subjects, and are worthy of more practice by the owners of mixed houses. By all means keep the plants thoroughly clean previous to blooming appearing. *Cinerarias* enjoy a fair circulation of air, plenty of light, a rich loamy compost, and to be assisted with weak liquid-manure as soon as the pots are full of roots. Should dipping be objected to it is a good plan to place the plants needing fumigation into a close box or case, as this method obviates the necessity for more Tobacco-paper or rag than is absolutely necessary, besides avoiding the unpleasant smell penetrating from the conservatory to the dwelling-house. Due consideration must be given to the amount of cubic space the smoke is to occupy, or dire results to the plants may follow. Far better have to do it twice than to overdo it once,

Finish putting all plants into their flowering pots now, and avoid too damp a temperature if still in cool pits; the loss of the lower leaves spoils their appearance. As there are often a few plants of exceptional merit, and it is impossible to preserve the same colours from seed, it may be well to close this note with a hint regarding their propagation from cuttings. As soon as the flowers are going over cut the stems down to within a couple of inches of the soil. Young growths will soon start from the base. These may be struck freely, or, better still, a little sandy compost placed around them will result in roots being formed, and they may then be removed and placed in small pots. P. U.

5063.—Aspidistras.—Even if the leaves should turn yellow through bad management that is no reason why they should split. That is probably caused when the leaves are being washed to remove dust or insect pests. The Aspidistra is one of the easiest plants to grow, and ought not to get into bad condition if planted in good soil and well drained flower-pots are used. The plant makes the best growth and succeeds best in a hot-house, but it is one of the best foliage plants to place in a dwelling-house. The leaves would turn yellow if infested with red-spider, or if the plants had exhausted the soil in which they are growing. In that case they should be broken up and repotted. J. D. R.

—This is due, one would think, simply to the leaves getting old and splitting, or it may be attributed to careless handling or being brushed against. You evidently do not treat the plant properly if all the leafage turns yellow, as the Aspidistra is one of the easiest things to grow well. Perhaps repotting is necessary. If so, give a shift into a size or two larger pot, and use a good heavy soil, with a few crocks in the bottom for drainage. So much, however, has been written of late about Aspidistras that further reference to them is unnecessary. Be careful always to sponge the leaves with tepid water at least once a week, and do not give too much water. —C. T.

Put in rather lighter soil and use more sand. In all probability this will stop the splitting and discoloration of the leaves. —E. U.

5061. Plumbago capensis.—This is a free-growing plant, and will require a shift into a larger pot in the spring, and two sizes larger will not be too much. Not only is *P. capensis* free growing and free flowering, but when it is planted out in the open border it thrives with the greatest freedom, and the more it grows the better it flowers. It is equally good as a pot-plant, and requires good loam, leaf-mould, and a little decayed manure with free drainage. —J. D. R.

—By repotting a plant of *Plumbago* in a pot two sizes larger, if the plant is well rooted, its flowering capacity should be improved. —E. U.

5065.—Dracenas.—These plants, being evergreen, ought not to be allowed to become very dry at any time, but the variegated-leaved varieties must be kept drier than the plain or green-leaved forms, as they are of a much more tender nature. Much depends also upon the temperature of the room. If a fire is constantly burning, and the atmosphere is, consequently, warm and dry, a good deal more water will be required than by a plant standing in a comparatively cool apartment, where there is little or no fire. A good general rule with plants of this nature is to give in this season just enough water to keep the foliage fresh and the soil just moist, but no more. —E. C. R.

5062.—Propagating greenhouse plants.—Early in March is the best time to insert cuttings of those plants named; even then they strike all the quicker if a little bottom-heat can be given them, placing the pots at the same time under a hand-light or in a propagating-case, where air is excluded from them. The light should be removed for an hour each morning to dissipate condensed moisture, which settles upon the glass during the time the frame is closed. If attention is not paid to this detail the cuttings will be liable to damping. —S. P.

—Early spring is the best time for this work, and the cuttings may be easily got from old plants placed in gentle heat to stimulate growth. Cut off the shoots just under a joint, and insert singly in small pots filled with light soil, or several together round the sides of 48 or 5-inch size. When ready to put in a pot, they should stand in a warm greenhouse. Give no air

at first, but as they get established more may be admitted. If you make up a hot-bed in the spring the cuttings may be struck upon this, and it will also suffice for raising seedlings and various other purposes. —C. T.

—The large-flowered Pelargoniums are usually propagated when the plants are cut down after flowering about the middle or end of July; but cuttings may be taken any time when they can be obtained. *Adiantum*, *Zonal Pelargoniums*, and *Fuchsias* may either be propagated in August or early in spring. I generally propagate at both seasons. —E. U.

COOL GREENHOUSE PLANTS.
Climbers.

Two capital cool greenhouse plants are *Celsia cretica* and *C. Anatum*, an evergreen and herbaceous in habit. The latter can be raised from seeds sown in spring in an ordinary hot-bed or greenhouse, and when large enough potted off singly and grown on with greenhouse-treatment, and it will thrive well in either a peat or loam compost. It bears yellow flowers during spring or summer. *Celsia cretica* (here figured) may be treated with success in an almost similar manner, and it may also be used as a half-hardy annual in the open ground in good soil in summer. These *Celsias* are occasionally attacked by thrips, and should then be carefully fumigated with Tobacco; and during

Cretan Malva (*Celsia cretica*).

the summer syringe the foliage on the underside to keep down red-spider. Manure-water is useful when in active growth. B.

5080.—A small greenhouse.—Ferns and foliage plants, such as *Aspidistras*, *Dracenas*, the hardier *Palms*, *Plumum tenax*, *Andra Sieboldii*, &c., will certainly thrive best in such a shady structure, though in the height of summer ordinary "Veranims" will bloom and last longer than in a sunnier position, and *Fuchsias*, *Begonias*, and a few others would do well. *Camellias* also are nice plants for a shady house. In the way of climbers, nothing will thrive so well as *Lapagerias*, white and red, and *Ficus repens*, clinging to the wall. No use to try *Roses*. —B. C. R.

—The most suitable creepers are the Red and White *Lapagerias*. Plant in a good, well-drained bed of peat, with a little turfy loam, and a few bits of charcoal. The general furniture of the house should be Ferns and foliage plants, but flowers may be had in summer. It will be better to trust to such things as *Fuchsias*, *Tuberous Begonias*, and those plants which can go to rest in winter. *Gloxinias* may do very well in summer. —E. H.

—You will not be able to do great things in the conservatory as it is so dark, but Ferns will eat largely into the selection, such kinds as *Adiantum cuneatum*, *A. decorum*, *A. gracillimum*, *A. Victoria*, *Asplenium bulbiferum*, *Utricularia gijensis* (the two last-mentioned in pot) being best adapted for hanging baskets. *Phlox*, *Utricularia exaltata*, a good Fern for a basket,

Ouychium japonicum, *Pteris erecta albolineata*, *P. c. Mayi*, *P. cristata*, *P. tremula*, *P. t. Smithiana*, and *Selaginella Kraussiana* and its golden-leaved variety. Two good creepers or climbers are the *Maréchal Niel Rose* and *Lapageria alba* and *L. rosea*, which bear white and red waxy flowers respectively. A good pot-bed must be made up for these, and the rising shoots each protected with a lump-glass, to prevent slugs devouring them. *Pelargoniums*, zonal and French varieties, *Fuchsias*, *Cyclamens*, Chinese *Primulas*, *Cinerarias*, and such *Primulas* as *P. cheucica* and *P. floribunda* may also be mentioned. At this season it might be furnished with the *Henth Erica hymenalis*, *Eperis*, the *Winter Cherry* (*Solanum elaeagnifolium*), and various forced bulbs, as *Tulips*, *Hyaucints*, *Hyacinths*, and *Crocuses*. Other things may be added, as *Eupatorium riparium*, *Lily of the Valley* (forced), and later on the yellow-flowered *Cytisus racemosus*, *Dentzia gracilis*, *D. crenata* &c., *Spura japonica*, *Azaleas*, and *Amuda japonica*, getting well-ripened plants. Mix with these such plants for their foliage as *Eranthis* in variety, *Erythra latifolia variegata*, *Coronilla glauca variegata*, *Aralia japonica*, *Yuccas*, and *Lammas*. None of the plants mentioned are expensive. —C. T.

5023.—A new greenhouse.—A width of 8 feet only is not much in which to group plants effectively and allow for a local pathway as well. On the whole, I think the best plan would be to make a narrow border, 1 foot or 18 inches in width, at the base of the back wall, and plant therein *Camellias*, and perhaps a few *Oranges*, *Plumbagos*, &c., to be trained on the wall, with some dwarf plants, such as *Primulas* of sorts, towards the edge. Then over the pipes along the front of the house have a simple ladder-stage, low, and consisting of not more than two or three wide shelves on which to stand plants in pots, the larger ones behind, and the smaller and dwarfer ones in front. If this is considered too stiff, the staging may be dispensed with altogether, merely standing the plants in more or less irregular groups, on the floor itself. Such plants as *Camellias*, *Myrtles*, *Azaleas*, *Spartanum africanum*, *Fuchsias*, ordinary "Veranims," *New Zealand Fox* (*Phoradendron*), *Senecios* and other *Lilies*, hardy (green-leaved) *Dracenas* and *Palms*, *Andra Sieboldii*, hardy and cool house Ferns, will be most suitable for such a structure, and for the majority, large plants will thrive better, and need less care than small ones. —E. C. R.

5066.—Fuchsia in a greenhouse.—Repeat the *Fuchsia* in February, or, better still, plant it in the border in the greenhouse, and the arch of glass be erected. —E. H.

Solanum and Poinsettias.—*Tombidge Wells Chrysanthemum* Shaw is remarkable for the grand specimens of these useful winter plants. I do not know which are exhibited in the greatest perfection, both being wonderfully well-grown. A good *Solanum capianatum*—sometimes called the *Winter Cherry*—is one of the most showy winter-berrying plants grown. Punctilious due attention is afforded in keeping them well supplied with water while growing, few insect pests attack them. They like rich soil, and a further aid of liquid-manure is beneficial. If once allowed to suffer for water, or half starved, they never present the same pleasing appearance until another season. An ordinary greenhouse temperature will grow this *Solanum* well; but the *Poinsettias* need a moist stove atmosphere during certain stages of development, and come with much brighter hues in fairly strong heat. —P. U.

Calceolarias.—Where these have been struck in cold frames or pit, considerable judgment is necessary to carry them through an extra severe or a mild and wet winter. In case of the former, lay a mat or a few old sacks over the frame, and do not open until the frost breaks. Should it be sufficiently severe to freeze the soil the cuttings are in, the steadiest they are allowed to thaw the better will they come through the ordeal. During all open weather admit a little air, and if mild, remove the lights for a short time during mid-day. Coddling, too much wet, and not enough air upon suitable occasions are the chief causes of failure with these. If you can tide over the sharpest part of winter, March and April will be their making rapid growth, when they should be gradually injured to full exposure, so as to secure stout, hardy plants. —P. U.

FRUIT.

NOTES ON HARDY FRUITS.

PRUNING PEARS.—Those who have not commenced this work may now do so, and persevere with it whenever the weather permits, or otherwise there will most probably be too much to do in the spring for all to be properly performed. The start should be made with Pears, and if there is not a mulching of ashes or strawy litter in front of the trees, let boards be used for standing upon, unduly trampling upon wet fruit borders having a most injurious effect. In the case of strong, well established trees, and which, say, have covered nearly or quite as much wall space as they will ever do, pruning is a very simple operation. It is these trees, however, that very often are too lightly pruned. If owing to a too sparing use of the knife the spurs are allowed to project 6 inches or more from the main branches, then much of the benefit that ought to be derived from the walls is lost. The fruit spurs ought to cluster round the branches and spring out not more than 3 inches from the wall, and in consequence be less liable to injury from frosts, the fruit also attaining a larger size and ripening better. Trees largely furnished with long, ugly spurs ought to either have these gradually sawn off to within 1 inch of the branches or else foreshortened to a back break much nearer the wall. In most instances this would be duly followed by a strong break of young shoots and fruit spurs, and which the cultivator should take good care to keep more within bounds in the future. Supposing the trees were summer pruned, spurs being left to a length of about 2 inches, the latter ought now to be further reduced to a length of 1 inch, in some instances, or where short spurs already exist in goodly numbers, to be cut quite hard back. Nothing is gained by crowding the spurs; therefore thin out where they smother each other when in leaf. If fruit-buds are scarce, leave some of the short shoots there may be with a fruit-bud at the end intact, cutting these back after the fruit has been gathered from them next season. Where there are any strong shoots available for furnishing blank space, lay these in to their full length. Ordinary shreds are of little service in securing strong Pear branches to the walls, those made of Bedford cord, huckskin, leather, and other trimmings being far more durable. Wrought-iron nails are also preferred to the ordinary brittle cast-iron wall nails.

YOUNG PEAR TREES.—More judgment has to be exercised in the treatment of these. It is possible to be too free with the knife when pruning these, though not when the spurs are operated upon. For reasons already given, all single growths not required for laying in should be freely cut back to a bud within 1 inch of the branches, the aim being to cause a good break next season. Where this was done last winter thin out the shoots resulting if at all crowded, leaving any which promise to develop fruit-buds to their full length and the wood growths 1 inch long. Older spurs should be treated as advised in the case of old trees, unhesitatingly foreshortening any that come out too far from the wall. All those horizontally trained should have the leading growths laid in to their full length, the only exception being the central growth. The latter should be shortened to a well-placed bud three courses of bricks from the last pair of side branches, and next summer it ought then to be possible to select and lay in two more side shoots and a central one for extending the lead upwards. Also freely shorten the leaders of fan-shaped trees wherever more branches are required for furnishing blank space. It is a mistake to shorten the leaders of cordons generally, unless very small and one or two more growths are required for laying in. If the young shoots are pruned at all, it must be done rather severely or to about one-third of their length, or the chances are the lower parts will be naked. Not pruned, they will break regularly throughout their entire length, and a fair percentage of the breaks may develop into fruit buds. Young trees swell very rapidly; therefore remove all old shreds that pinch or unduly press against the bark. Horizontally-trained trees in the open and also cordons should be treated much as advised in the case of wall trees. Pyramids and standards should be pruned similarly to Apples.

APPLES.—More of these are grown against walls than formerly, especially where extra fine exhibition fruit is desired. Horizontally-trained, fan-shaped and cordon trees should be pruned as recommended in the case of Pears, the advice to keep the spurs well back to the branches in particular being acted upon. Very fine fruit is frequently borne on the points of short shoots, and all these, therefore, should be closely examined before cutting them off. The topmost branches on espalier-trained trees are very apt to become the heaviest, a thicket of spurs quite smothering those on lower branches. Keep these within bounds on the younger trees, and freely thin out the spurs on older trees. Till the trees are well formed it is advisable to keep pyramids carefully staked upright, the leader also being kept straight. Shorten the latter to about one-third of its length; this will lead to the formation of more side shoots and a fresh leader. Side branches should be shortened back if more shoots are required, otherwise they had better be left to their full length, only those not required for furnishing being cut back to a length of about 1½ inches. Young trees kept hard pruned require to be root-pruned rather severely in order to bring them into a fruit-bearing state; whereas those allowed to develop more naturally seldom require this treatment. Pears are more easily grown in a strict pyramidal form than are Apples, but varieties differ considerably in their habit of growth, pegs and rat twine being frequently used for bringing some of the branches down to a more horizontal position. Bush-shaped trees are the most easily trained. Cut out the leader of a pyramid as received from a nursery, and allow the side branches to grow more upright. The latter would soon commence bearing fruit if not pruned, but in some instances would not be stiff enough to support a heavy crop. This difficulty can be got over by using a few stakes, or if preferred the branches could be pruned to about half their length and allowed to extend more gradually, being stouter accordingly, but they would be much slower in coming into bearing. Keep the centres of all the trees, whether young or old, open, thinning out the branches where they cross and mutually shade each other, most of the lateral growths being freely cut back. Trees that are large enough and in a fruitful condition should have all leading branches cut hard back, but where hard pruning is constantly followed by thickets of wood growth, leave all the best placed young shoots, and early productiveness will be the result. Leaving young shoots to their full length thinly all over either unproductive or stunted old trees will put new life into them, that is if there is any such thing as accomplishing this. A considerable number of large old trees there are of varieties not worth growing, and these ought either to make room for young trees of superior sorts, or else be headed down and regrafted.

W. I.

THE MOST POPULAR PLUM.

If the truth could be arrived at as to which is the most popular Plum in cultivation the verdict would be given in favour of Victoria. No other variety possesses so many good qualities as this fine old Sussex Plum, and it is very certain that it has been by far the most extensively planted during the past ten years, or, say, since the fruit-planting fever has set in. It is a veritable rent-payer. While the other varieties are growing into larger and serviceable trees the Victoria is producing enough fruit to help, if not to wholly meet current expenses. In common with other early and heavily productive fruits, trees of Victoria rarely attain a large size, nor are they ever likely to do if allowed to bear as much fruit as may set on them. In the orchards it forms a medium-sized, somewhat spreading standard, and for this reason, and also from the fact of its precocious habit of bearing, it is just the sort to plant in rows midway between varieties and kinds that attain a much larger size and are slower in coming into full bearing. It is as low or medium height standards that this variety should be grown, the habit of growth not readily lending itself to bush or pyramidal training. The Victoria is also well worthy of a place against walls of any moderately warm to comparative cool aspect, a long succession, lasting, say, from the middle of August till the middle of September, being had by varying the sites of the trees.

As a poor man's Plum it has no equal, and if landlords are called on or feel disposed, as I maintain they ought to do, to provide the poorer tenants with fruit-trees, a trained tree of Victoria for the cottage walls and a standard for the open should be among the first selected. Hereabouts the trees seem to thrive fairly well everywhere, in moderately strong loamy soil evidently suiting the variety. It is not particular, however, as to soil, only the trees ought not to be impoverished at the roots, or an early failure is inevitable. Overcropping is the mistake most often committed with this variety. If there is any fruit at all, and it is not often it fails, this is almost certain to set in great clusters. The fruit ought to be early thinned out, this operation being rather severe if the crop is heavy and should not be delayed till the natural process or premature dropping commences. One thinning is not enough. When the Plums are changing for ripening some ought to be used in pies, and when embouring, a heavy thinning should take place, the fruit then being quite saleable and fit for making into preserves. Not being overlaid, the trees will swell the reserved fruit to an extra large size, the quality also being far superior to that of fruit gathered from heavily cropped trees. Fully developed, well-ripened Victoria Plums are really quite good enough for dessert, and will always sell readily.

11.

BIRDS VERSUS FRUIT-BUDS.

At this time of year a great many small birds are destroyed with a view to the protection of the buds of fruit-trees, but I question whether a good many of these supposed feathered foes are not really the friends of the gardener. I have lately watched both tom-tits and sparrows busily engaged on fruit-trees, but certainly they did not hunt the buds, but were picking off insects and the eggs of various kinds of pests that prey on fruit-trees. The tits were especially active in searching about the shreds and fastenings of the fruit-trees where either insects or their eggs were apparently safely hidden away for the winter, and where it would be difficult to dislodge them by any other means. Sparrows are unfortunate in having a very bad name; certainly they do some mischief at times, but I think they do a deal of good at times as well, as during the past summer I noticed them frequently hanging to the tips of the shoots of fruit-trees picking off green and black-fly, and carrying them away to their young ones, and the quantity a few birds would clear off is incredible, and doubtless we should have suffered a good deal more than we did from insect pests during the drought if birds had not come to our aid. The Bullfinch is, in my opinion, the worst enemy we have to fruit-buds, as they come out of the woods in winter and spring, and pick out the flower-buds in a wholesale manner, and unless checked will soon destroy all chance of a crop, and with fruit-bushes they spoil the buds entirely, as they leave the centre clear of all growth, and only a few buds at the tips of the shoots that are really useless for making a crop of fruit or shoots for future crops, and in the winter they work much more quietly than in the spring, when they make a piping noise, and anyone valuing their fruit-trees should keep the Bullfinch at a distance, but rather invite the other birds.

J. G. H.

Staking fruit-trees.—I have seen many market plantations of trees which have been left unstaked, and I have never found that any good results followed. In most cases the stems become unduly warped, the buds lop-sided or injured, and the whole plantation has worn a very wretched aspect. The old notion of planting deeply to secure for the roots a good grip of the ground, trampling in on them several inches of soil, and making it as heavy and hard as possible, is happily an exploded one. It is far wiser to plant comparatively shallow and give the tree proper support than to trust to such methods. Happy are those planters who have at command a large quantity of stout Ash, Hazel, or Larch stakes to make into tree supports. These, if sound and new, should endure at least two years, by which time trees will have secured good root-hold of the soil. If these be properly pointed and smoothed off at the bottoms, their forcing into the soil can

hardly be productive of harm to the roots. It is best to have the stakes a couple of inches from the stems, so that the ties may be rather loose, and have for the first year, to wedge them slightly, a wad of hay or Grass. The leads in that way secure a little play—indeed, quite enough for motion without inducing friction. —A.

A "Morello" Cherry.—This variety is so often grown on walls and on northern aspects that it is only of late years any attempt at growing in quantity in any other form has been made. The Morello does well as a bush or standard, and one great advantage it possesses over sweeter kinds is that birds will not attack them so long as they can get other food; they also sell readily, and, unlike many other fruits, they will keep, so that when there is a glut of other fruit Morello Cherries can be kept and sent in as required. To the market gardener and private grower this fruit is of great service, as when well ripened and nearly black they sell readily late in the season as dessert fruits. When grown as bush trees Morello Cherries are readily managed, and may be planted between other taller trees if not too much crowded. As a standard the Morello is equally useful, but not so easily gathered, and is more liable to injury from rough weather, wet, and early autumn frosts, which crack the fruits and render them useless, so that the bush form has much to recommend it, and is preferred by large growers. Kentish Red is also useful grown as a bush, and is valuable for nets, or preserving, or for using before the Morellos are ready. When the Morello is grown in this form, thinning of the shoots should be attended to during the summer months, as this greatly improves the size of the fruits and allows those left to get well ripened by exposure to the sun. When grown in bush form, small birds attack them they are readily netted, if kept of moderate size. —G.

Peaches in pots.—I have often observed in the case of pot Peaches that the bloom buds fall early, leaving a very thin set of fruit. This failure was ascribed to various causes, but I am disposed to think that sufficient water is not given to pot trees in the winter, the presumption being that with trees at rest water is hardly essential to existence. And yet Peaches go to rest just as much when planted out in the open ground, and, as a rule, whilst so at rest obtain naturally the chief of their water supply. If that be so, is it not very probable that with the roots comparatively dry in the pots for several weeks the buds must necessarily suffer? To have kept the roots moist would have kept the buds p. uup. —A.

GOOD LATE PEARS.

THERE is an abundance of good mid-season Pears, but when you come to the really late keepers there are not many reliable kinds, for all Pears do not flourish in our locality, even though it be a favourable district as far as soil and climate grows, for we can grow the majority of Pears here with little trouble, but certainly some of the late sorts are by no means satis-

Fig. 1.—Pear "Josephine de Malines."

factory. The following are the best with me—viz. :—

JOSEPHINE DE MALINES (Fig. 1) with me grows freely and crops regularly, but not very heavily, the fruit being clear-skinned and handsome, and of good flavour, and is quite as good from open bush-trees as from wall-trained ones.

BERBE RANCE (Fig. 2), a fine, old variety, attaining a good size, and greatly benefited by wall culture. It is of a russety green, changing to yellow when ripe, and is very sweet and juicy.

CHAI MONTE, one of the most regular and free-

croppers of any Pear, requires thinning for the fruit to attain a good size. It is of a peculiar and very agreeable flavour, and does well in the South of England as a standard or bush-tree.

KENTISH MOSAIC, one of the best of winter Pears, requires a wall to do it well. Its greatest fault is that of casting its fruit during the growing season; gives a long succession of ripe fruit.

NE PLUS MEURIS (Fig. 3), a very free cropper, the fruit rather small, but a reliable sort.

Fig. 2.—Pear "Beurre Rance."

The crop needs thinning, as it sets in large clusters.

WINTER NETS, a rather weakly grower, but free cropper, and the fruit of the finest flavour; requires a wall, even in the south of England, and well repays good culture. A russety Pear.

GLOR MONTAIGNE.—This is one of the best of late Pears, especially after a warm season like the last summer was. It is now probably the best flavoured Pear brought into Covent-garden Market. It is a free-bearer and does well in moist soils, excepting those that have cob clay beneath.

J. Groom, Gosport.

5000.—Treatment of Cherries.—If the Cherries are meant to be trained in the usual fan shape they must be cut down to within half-a-dozen buds of the base, and from these buds shoots will be produced next spring that will form the future fruiting-branches of the trees. They must be trained to stakes during the summer, so as to keep them in the exact shape needed for the wall, as it is in the proper laying of the foundation of the tree that its future qualities will depend. An evenly-balanced head of shoots is of the greatest importance to a wall-tree. —J. G. H.

5084.—Pot Vines.—If the Vines are strong and well-ripened they ought to carry a few bunches of fruit. Although the length is not always a criterion as to what they are capable of doing, cut back now to 6 feet, and keep inside, but do not let the roots get dust-dry. As they are not to be forced, and if they are Black Hamburgs, or some other free-bearing variety, they will probably show half-a-dozen bunches or so. The Vines may be top-dressed just previous to starting, mixing a little of Thomson's Manure or some other good artificial with the turfy loam. The Patent Silicate Manure I have used for Vines in small pots with good results. As soon as the Vines get fairly into work, and the bunches have shown, enclose the pots in wire netting and fill the netting in with rich compost—i. e., place each pot in a heap of rich compost, and encourage the roots to make out to feed. Pot Vines must have plenty of enrichment, and it is better to give it in this way than to deluge the soil in the pots with strong liquors. —E. H.

I would not shorten the rods more than 1 foot, not that you want the whole of the remaining length to furnish bunches of Grapes, but because the more eyes you have on them, the more leaves they will produce, and the more leaves you can secure the larger the bunches of Grapes will be. You had better shorten back the rods at once, and stand the pots on a cool floor or border, and during the winter keep the soil about the roots regularly moist. When you see indications of the eyes starting into growth in the spring, place the pots up to the light, so that the rods can be trained 14 inches from the glass, but until the shoots appear leave them (the rods) in a horizontal position, even if the end of the cane is below the rim of

the pot it is better than being above it, as the buds will break more regularly for the rod being so placed. Allow all the bunches to remain until you can see which is the largest, and then remove all but six on each Vine. Water the roots moderately at first, and as soon as the berries are formed give liquid-manure regularly, and sufficient each time for it to run out of the bottom of the pot. At this time you should also stand the pots on pans or shallow boxes filled with good rotten manure, and at the same time pile up a layer of manure on the top of the pot 3 inches thick. Some growers place a zinc band round above the pot to confine the manure, others use pieces of slate. In any case, stimulants of some kind the Vines are bound to have, or both bunches and berries will be small. You will have to give them water twice a day in very hot weather after the berries are formed, and do not be tempted to leave a greater number of bunches than I have named. —J. C. C.

Cut the rods back to within 5 feet of their base any time this month. From this length of rod half-a-dozen bunches may be taken next year, and especially if the Vines are not forced. Pots 14 inches in diameter should be employed, this size affording ample root space. A compost of loam and partly-decayed horse-manure—three parts of the former to one of the latter. Add to this finely-ground bones at the rate of one quart to every bushel of the compost. Pot firmly any time during next month. From now until then place the Vines out-of-doors in a sheltered position, protecting the pots from frost. —S. P.

5066.—A vinery border.—As the Vines are planted outside, it is not likely there are any roots inside. If there be, I should say do not crop with anything else. This may be easily ascertained, and in any case Tomatoes might be grown in boxes or large pots if they will get light enough under the Vines, as in summer they are frequently so grown in vineries. I should be disposed to plant the Tomatoes in pots or boxes trained to stakes, and then in July take them outside to ripen; this will relieve the vinery at the time when, if left in, they might do harm, especially if disease should attack them. I always think by July, at any rate, if the Vines are worth anything at all they should have the house to themselves. —E. H.

If the roots occupy the whole of the inside border they ought not to be interfered with by planting other subjects in the same, because the Vine-roots ought to be close to the surface for the benefit of the Vines. If they are there nothing could be grown on the border with satisfaction. Besides, if Tomatoes, for instance, were planted on the border, the Vines growing above would rob them of all light. It is impossible to cultivate Tomatoes in such a position as this with any prospect of success. If the border is not occupied by the roots of the Vines, the outside border being large enough to afford sufficient space and nutriment for the Vines, there is no reason why such things as Winter Lettuce or Cauliflowers may not be pro-

Fig. 3.—Pear "Ne Plus Meuris."

ected during the winter by rigging them up and planting the roots in the border. By planting Potatoes at Christmas a crop of early tubers might be got off if the Vines are brought into growth slowly afterwards with the aid of solar heat only. —S. P.

Planting a few Tomatoes on a vinery border would not do very much harm, even if the roots were inside; but if the Vines, and consequently the roots, are outside, they could not do any harm. If the roof is covered with vine-leaves, the Tomatoes would not do much good. —J. D. E.

RULES FOR CORRESPONDENTS.

Questions. - Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 57, Southampton-street, Garden-gate, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in order to enable us to return the paper if it is not used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, notes, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5102. - Japanese Chrysanthemums. - Will someone tell me the names of the purest-red Japanese Chrysanthemums? - H. M. P.

5103. - Scale on Ferns. - Would someone kindly tell me how to destroy scale on Ferns and how to prevent it coming, if it can be done? - J. W.

5104. - Size of Tomato-house. - Will someone kindly inform me the best size for a Tomato-house, more especially as regards the height? - ASSISTANT G.

5105. - Lillium Kramerii and auratum. - Will somebody tell me how to plant the above Lillies, and how many in each pot, &c.? - G. H. HILKIN.

5106. - Creeper for a greenhouse. - Will someone name a good creeper for a small greenhouse (warmed), not too luxuriant, the space being 12 ft. x 8 ft.

5107. - Grafting a Cherry-tree. - I have a large-sized tree, which bears only small fruit. Will someone please inform me when to graft this? - F. L. SUDWELL.

5108. - Single Chrysanthemums. - Would "E. M." give me a few hints as to the general culture of single Chrysanthemums for the production of plenty of bloom? - B. B.

5109. - Growing Mushrooms. - Will anyone kindly tell me how to grow Mushrooms, as I want to send the paper on to a friend of mine in America who has begun gardening? - W. G.

5110. - Plants in Rhododendron-bed. - Will anyone kindly tell me what flower or flowers will grow in peat-beds with Rhododendrons? I want to furnish my beds. - KEENE.

5111. - Oypthomandra betacea. - Will anyone give me any information of the fruit? viz., as to its adaptability for a town garden, &c. It requires to be grown in heat, and if easily grown? - SMITHSON.

5112. - Acaelypha macrophylla. - Will someone kindly tell me how to treat this plant? I have got it in a greenhouse (heat about 45 degs.), and all the leaves have withered and fall off. - CONSTANT READER, "Purley."

5113. - Sun-dials. - What is a good book on sun-dials besides Mr. Olry's? If with illustrations so much the better. And where is the best place to get a sundial? I want one to stand in the middle of a small lawn. - A. A.

5114. - A forcing-house. - I propose erecting a forcing-house, three-quarters span, 30 feet long, 10 feet wide, 10 feet high (on 2 feet 6 inches x 3 feet walls), and shall be glad to know which boiler is best for heating it? - T. B.

5115. - Rooting cuttings of fruit-trees. - I should be thankful for a few hints on rooting Cherries, including Foremost Wood, Baroness Proved, Morella, May-duke, Knight's Black, also Pear-tree cuttings? - LEA SONS, Dublin.

5116. - Moss Roses. - I wish to make a bed which has pegged-down Moss Roses bright in the spring and autumn. For next spring I have put "Clary of the Snow" through the bed. Will they hurt the Roses? - TRUSSARDI.

5117. - Treatment of Agapanthus. - Mine do very badly. I have had the plants about four years. They are alive, but have made no progress. I have them in a round-house at 45 degs. to 55 degs. What course shall I pursue? - E. H.

5118. - Begonia-seed. - I shall feel obliged if someone will tell me what time Begonia-seed should be sown? - If on bottom-pan, or in a rool frame, and general treatment of plants from seed up to blooming them out-of-doors next summer? - BELFAST.

5119. - Pompon Chrysanthemums. - Can Pompons be obtained in a few hints on raising Chrysanthemums which are large and round like a ball, but the petals more like Japanese. Will someone please tell me the name of these? - B. M. P.

5120. - Beet Raspberries. - Will someone kindly give me the names of two of the best varieties of these, best croppers, and for general purposes, suitable for the North of Ireland? As I only grow about forty stools two kinds will be sufficient. - BELFAST.

5121. - Peat-Moss-litter. - I use Peat-Moss in my stable. For what can I use it with advantage in my garden after it has served its purpose in the stable? Is Peat-Moss non-conducting material suitable for plunging pots into in a cold frame? - H. S. B.

5122. - Dressing for a tennis-lawn. - Will someone kindly say if it is safe to use "root" or "lifter" for the top-dressing of a tennis-lawn? The soil is not of the ordinary black loam, but is quite brown, as it is mixed with iron, and I am afraid to use it on grass? - Soot.

5123. - Tuberous Begonias. - Will someone kindly advise me on the treatment of Tuberous Begonias? I bought a few tubers last week, and do not know whether I ought to put them now or leave them till the spring, and as they are marked a very choice I am rather anxious about them. - HENRY H. MINDY.

5124. - Chrysanthemums for South Africa. - One of my neighbours wishes to send some Chrysanthemums to South Africa, and I should feel much obliged if anyone would tell me how they should be packed, and when they should be sent, and also whether plants or rooted cuttings are best for the purpose? - A. H. M.

5125. - Planting a Vine. - Will anyone tell me when to plant a Black Hamburgh Vine? It was three years old and in a 12-inch pot. It flowered this time, but did not fruit. I want to plant it in a tub 3 feet across, and 2 feet deep to be grown in a cold house. Any hints on growing it will oblige? - W. G.

5126. - Espalier fruit-trees. - Will anyone kindly give me instructions for making wooden Espalier frames for fruit-trees? They are to be raised in square plots of ground to separate the flower-border from the vegetables in the centre. I want them to form an ornamental screen, and incline to have them painted. - A. A.

5127. - Monarda didyma and Tiarola cordifolia. - Are these plants difficult to grow, and do they object to some soils? I have purchased plants of them in autumn and in spring, and on both occasions they have died down, and never reappeared. Perhaps the soil here does not suit them? Will they grow from seed? - ST. S. FLOWER.

5128. - Crochids for a cool greenhouse. - I should like to have a few Crochids in my cool greenhouse. I cannot find any except the ones I should be much obliged if anyone would name half-a-dozen of the cheapest sorts, and where to get them? I thought about buying them next February. Locality, Jamaica-street, London, E. - H. J. H.

5129. - Planting Tea Roses. - I should be pleased if some reader would kindly inform me which would be the best time to plant Tea Roses? I have a few of H.P.'s that have done very well. My garden faces south, and is pretty well sheltered. What soil would suit best? I have one part rather heavy, and the other part rather light soil. - NORTH LAMINGTON.

5130. - A north wall. - I have a bare wall facing north, near a pasture where cattle and horses are turned out all the year round. Can anyone recommend a fairly quick-growing evergreen creep or other thing which will cover my wall, and which will not trumpet with? If suggestions are limited to try, which I try is the quickest growing? - H. S. B.

5131. - Large Tomato. - Will someone kindly give me some information about a Tomato named "Losa Pimlico"? It is described to me as being 10 inches in diameter, and shown during the last summer in Kent. I should be glad to know something more about this peculiar fruit, and I desire many others of your readers would also. - J. H. T.

5132. - Forcing Strawberries. - I have about 200 Strawberry-plants for forcing. They are well rooted and have got good crowns. I have just taken them in winter glass. Will someone kindly tell me when is the right time to set the fruit? I can hold some fancy prices can be made if they can be got at the right time. I have got a good forcing apparatus. - AMSTERDAM.

5133. - Roses for an arch. - Will someone kindly tell me the best Roses (Perpetuals) to grow over an arch made of wire, which surrounds my door? I have already a Floire de Hesse growing on one side of the arch against the wall, and Waltham Climber No. 1 on the other side, and want something for a contrast with these. I prefer a compact-headed Rose rather than a very open, loose flower. - S. J.

5134. - Outdoor Chrysanthemums. - When is the right time to take cuttings from outdoor Chrysanthemums? Should they be cut down after flowering? How long can they be cut down in the summer to prevent them growing very tall before flowering? Kindly give reasons. Should the cuttings be taken at the roots or otherwise, and should old plants be transplanted after a few years? - M. C.

5135. - Early vegetables. - To last year I planted six for use in January, February, and March, what are the best kinds and hardest to sow, and when should it be done? I sowed some Calabages and Cauliflowers in April, Sutton's Earliest and Knight's Cauliflowers. The Calabages are after about two months, and Cauliflowers also. Would some practical reader advise and put me right another year? - IRISH SAXON.

5136. - A border of Gazanias. - I have a border of Gazanias which are still in bloom. Up to last week they were in full flower, but the sharp nights of the 1st and 2nd last, cut them slightly. They are still, however, quite gay, and have been in bloom ever since June. I may add that we have had many frosty nights this autumn, and that though I live in Devonshire the climate here is cold, and the border the most exposed in my garden. Is this flowering not rather unusual? - B.

5137. - Culture of Seakale. - I should be very glad of a few hints on this matter, as I am thinking of making a bed? When is the proper time for planting it? And the best aspect for a bed? When might I cut from it? My soil is rather heavy, with a clayey subsoil, and I have been told that it thrives best in light soil. Would plenty of root-scrappings improve it? Does it require deep cultivation and any manure at planting? What would be the right distance from row to row, and from plant to plant in the row? - LONDON.

5138. - Chrysanthemum in the open ground. - Will someone recommend me a list of good Chrysanthemums for growing entirely in the open ground? I knew a garden that was quite a sight in autumn with outdoor Chrysanthemums, but the present gardener, preferring to grow under glass for exhibition, has lost them all, and can give me none. Some good yellows and reds wanted especially. Should I grow from cuttings or strike now, and plant out in spring? Please advise. - LONDON GARDEN.

5139. - A garden pit. - I am having a brick building in the garden, 24 feet long, by 6 feet wide, with slights for

growing Cucumbers and Melons in summer, and for keeping "Grenium" cuttings and of other hardy things in or the winter. I have a forwarding material of any sort, so that I must entirely depend on either a set of hot-water apparatus. I should be very much obliged to "J. C. C.," "B. C. R.," or any other person who would kindly let me know how to make this pit properly, and also how to heat it? - THAMES.

5140. - Treatment of a Lemon, &c. - I have a Lemon growing in ainery which will only be heated slightly during the winter to keep out frost. The Lemon is full of mealy-bug and scale and sickly. I intend to cut it back and give it a dressing of paraffin-oil, letting it take its chance of living. I intend to kill or mire it. Would someone kindly say when would be best to do this, and when I might, should it survive, expect it to flower. The house to be started about March? I have the Vine now outside the house. Is this a good plan? - IRISH SAXON.

5141. - Marechal Niel Rose in a greenhouse. - I planted a Marechal Niel Rose in one end of my greenhouse last January; it has made enormous roots. I measured one shoot, which is 10 feet 6 inches, and another 13 feet in length; out of these shoots have come side-shoots, measuring each 4 feet to 5 feet long. A great quantity of the wood is unripe. I have pinched one or two flower-buds off. I should be very glad if someone would tell me how to treat the plant in future, as I should like to get a good quantity of bloom next season. The greenhouse is heated with a fire, and I am only keeping up sufficient heat in winter time. I have a mixed collection of plants in the house. - W. H. H.

5142. - Making a garden, &c. - I am building a villa, and at present time trenching half an acre which I intend for a garden; the back or lower part of it is to be the south and slightly shaded by trees, the house-land and shrubbery will occupy another half acre; the whole is enclosed by wire-fence planted with Thorn and Privet. In the garden down the fence, facing west, I intend to plant fruit-trees, trained on parallel wires from the enclosing fence, across a 32-foot border. What are the most suitable hardy growing sorts for this purpose on south side which is shaded by trees? I intend planting borders of Raspberries, trained or cross wires in same way across border; will this do? The half acre of garden ground is almost square. What is the best plan to plant with fruit-trees, preserving portion for flowers? - BELFAST STRICKLAND.

5143. - Cytisus plants in a drawing-room. - I shall be much obliged to anyone who will tell me why my Cytisus plants in the drawing-room do not develop their flowers, and what I can do to get them to do so. They were perfectly healthy plants, and covered with spikes of flower-buds when I took them out of the bed where they were pinched during the summer. I set them for a few days under a sheltered wall, and then brought two into the drawing-room in a short time, but they have all now begun to wither and drop off, and the plants looked so bad that I put them into the greenhouse and brought in another one which I thought ought to have been acclimatized, and which was partly in bloom. Only a few leaves of this one dropped, but the flowers and buds are withering, and there is not one open or about to open on it. The same thing has happened to a Primula identification; the flowers will not develop and gradually die off; it is most disappointing, the leaves and buds are all now flower-stalks which dropped at the bottom. - DANIEL.

5144. - Growing two crops of Tomatoes. - I should like to know if I can grow two crops of Tomatoes next year, and the following: middle-early, 9-foot plant, with two 4-inch pipes on each side, and another 6-foot by 31 feet, with 6-foot ridge and 4-foot sides, having the 4-inch pipes on one side and two on the other. I propose to sow seed first week in January, grow them up long in the space will admit in the smaller house, and for fruiting plant out in the doors of both houses. Can I have fruit early in May? If so, the first crop should be off by, say, the end of July? The way I propose getting a second crop will take cuttings in June very early in the morning on the side, as I have no other glass of any kind, transplanting them to the houses when the first crop is off, and by this means fruiting them from, say, September till end of year. Is this the best method I can adopt? There are one or two other points I should also be glad of information on. I set, in three or four, again in using pots for Tomatoes? I grew some last year without any pots right from seed onwards, and they were quite as early and much sturdier than others that I grew in the pot system. And shall I have sufficient heat to fruit the second crop? And, as a second crop of Tomatoes likely to be as remunerative as a crop of late Chrysanthemums? I may say I run down some Tomato-plants after fruiting at the end of September this year to within 4 inches of soil, but they did not, as I had expected, produce any fresh growth, so that I presume they will answer my purpose better than that method. - G. W. D.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5145. - Cypripedium oenanthum (C. Beecheri). - Yes; this is a very pretty form of this plant, but I cannot see that it has anything to do with the variety known as superbum. It is a magnificent Slipper Orchid, one of the very best hybrids we have had sent out. Both very rare in the Messrs. Vitch, who, if they had raised nothing else, would deserve the praise of every Irish-gardener in the three kingdoms. - M. B.

5146. - Oncidium varicosum (G. Harper). - You may depend upon it the spike of this will be open at Christmas, and it will remain gay for a month or more afterwards. I am very pleased that you should have been so successful with this plant and with O. tigrinum, the latter plant having twelve flowers open, yielding a delightful fragrance. Yes; they will last a long time yet, notwithstanding their having been open a fortnight. - M. B.

5147. - Fancy Orchids (G. B.). - The flowers sent are varieties of Pterodictyon, Stills, and Detoneras, none of them being of the slightest use or value to the ordinary grower of Orchids, and all of them not so immature with mysterious from various correspondents I might endeavor

To insure them for you; but it would take me a long time, I advise you to send either specimens than you sent to me, and in a more perfect condition, to Kew, asking them to kindly name them.—M. B.

5143.—**Odontoglossum blandum** (*H. Thunberg*).—This flower sent for blandum is nothing like it, but it is simply *O. Alexandra*, a small form and pure-white, which is the true form of the plant as figured by Bateman. The spotted form being called *O. blundii* by Kuhn and Bach, and he used to always assert that he could not find the difference, but there is really no difference. *O. blandum*, however, is a very different plant with smaller flowers and a dull more colour.—M. B.

5149.—**Epidendrum ciliare** (*H. Thunberg*).—This plant is very pretty, but your friend was quite right when he told you there was no demand for it; but, nevertheless, I should like to see if you can put up with it, but when it is collected with *Catleya* plants of, perhaps, a rare variety, and is sold for it, when it comes to flower it is no wonder the owner gets disgusted with it. The plant was first introduced upwards of a hundred years ago, and it is widely spread over tropical America.—M. B.

5150.—**Balanium culcitra**.—*T. Gibson* sends a specimen of this plant which comes from Malera and the Azores Islands. But some few years ago Mr. Low, of the Clayton Nurseries, assured me it was getting to be a rare plant in its native habitats. It makes a bulb and leafed plant in a good fernery; differing very slightly from *Balanium*, saying in having a filament stem instead of an erect one. The pots in which it is planted must be well drained, using soft loam, peat, and sand well mixed.—J. J.

5151.—**Oranthe Vetchi** and **O. vestita** (*G. Pöhlen*).—Yes these are very pretty, and you maintain the reputation of the Lancashire lady by growing them. When I visited to be a frequent visitor to gardens in that county I observed how well these plants were done there, the thing I most point out to your samples of *O. Vetchi* that you have by no means the best variety; the flowers being very pale coloured. You should look to this; but your *O. vestita* are excellent, both the yellow-eyed and the crimson.—M. B.

5152.—**Vanda Amesiana** (*C. M.*).—You should keep this plant in the warm end of the *Odontoglossum* house. You could not expect them to grow fast in this season of the year. The temperature of the house will be sufficiently moist for it; it is maintained right for the winter months. Let me know when you have the plant in flower, and I should like to see a single bloom. I am very anxious about this species. I want, I think, to see the plant as it is originally appeared with the Messrs. Carr, of Glasgow.—M. B.

5153.—**Cypripedium Charlesworthii** (*G. T.*).—I must acknowledge that I have not yet seen this plant, which everyone that has told me it is a great beauty. Perhaps, if the Messrs. Charlesworth, who are selling it so freely, from a spare bloom, they would send me one to cheer me up in this dull time. I know enough of it, however, to advise you to add it to your collection; if you can afford it. I cannot tell you its price, but you could easily know by applying to Messrs. Charlesworth and Littlehugh, Bedford.—M. B.

5154.—**Cypripedium insignis** (*Reichenbach*).—The flower you send I have not had, makes a very handsome looking specimen. It is a very fine plant, and I think you do never see in that part. They are pale green and persistent, and I have seen a plant fully occupying a space it foot or more through; this will give one some idea of the size it will attain, and in such conditions it shapely looks majestic. It should be potted in good light-yellow loam, mixed with fibrous peat, chopped up with a spade and not sifted, mixed with a good bit of sharp silver-sand, the pots to be kept in being thoroughly well drained; and it requires very liberal watering during the growing season, and even in winter it will be found a thirsty subject. It likes also the temperature of a warm stove, and to be treated to a liberal amount of shade.—J. J.

5155.—**Zygopetalum Mackay**.—*A. Gubling* says he has a plant of this species coming into flower with seven spikes, but he finds the opposite buds are turning yellow, and will fall away. What is the cause of this? Now, without knowing anything more about the plant, I should say in my opinion it is the matter with the roots. Either you have got the drainage stopped or partially so, and the soil has become sunken, or, on the other hand, you are starving it for want of water. Attend to its wants which way it may need it, and do not lose all these beautiful flowers with their delicate fragrance.—M. B.

5156.—**Odontoglossum Rossi Amesianum** (*H. Thunberg*).—This is the name of the variety you send flowering at a very unusual time, for it usually blooms in the spring months; however, perhaps you are about to have a variety which will flower twice in the season. But this will be in doubt certainly at the Christmas and New Year season, at which times, besides this, that can be used for purposes of personal embellishment are always welcome. This variety has much more vibrant brown in its than the typical form, and, like the type species, is one of the rooted of the root hybrids, and it should be grown by everyone.—M. B.

5157.—**Rodriguezia secunda** (*H. Thunberg*).—This is the name of the pretty little rose-coloured flower you send, and which you say you received from the West Indies. It is an elegant little plant, which thrives well, because this does not appear to be prouder for next year; but put the plant into a temperature which does not fall below 60 degs., and soon after the turn of the year report it into some good brown peat-fibre and Sphagnum Moss. Pick away from the old soil any sown or decayed pieces, and do not over-pot; keep the atmosphere moist about it to prevent the attacks of black fly, and if the season advances give a sprinkling of water on the surface daily, and let the know if you save the plant and succeed in flowering it in 1894.—M. B.

5158.—**Ocologyne cristata**.—*J. Gubling* writes, saying he has a plant with over two hundred buds upon it, and he would give anything if he could get it out by Christmas. Well, if my friend's blooms are forward enough for him to count I should say there is very little fear of their being open and well set up by the time mentioned. I should advise him to put the plant in about 65 degs. of heat, and to keep the atmosphere nicely moist, and avoid a great excess of wet, keeping the plant dry watered at the roots. As these flowers last a considerable time after they have opened, my friend will have a very grand ornament both for the Christmas and the new year also. The plant is flowering early.—M. B.

5159.—**Odontoglossum grande** (*H. Thunberg*).—The plants should be kept as dry as you can keep them now, without shrivelling the bulbs and leaves, and keep it a little warmer than the rest of the genus, and in about two months they may be potted in some good fibrous peat and Sphagnum Moss, the pots well drained, and they may occupy the warm end of the *Odontoglossum* house; they may be kept fairly moist. Now, this is a species that enjoys a good deal of air, and more than most of the *Odontoglossum* so let them always have air, which will induce them to make good firm leaves of the consistency of good leather aprons, and produce good spikes of bloom. Treated in this manner I cannot see why amateurs fail with this beautiful species.—M. B.

5160.—**Orchid house temperatures** (*Orchid News*).—I am very pleased to see what you have in flower. I think, however, you are keeping them somewhat too cool, and for some of the plants I may say much too low, which will impoverish them and tend to prevent them growing strong enough to flower next season. There is another thing which is absolutely wrong in naming *Catleya* plants. You should always have a determinative name. It should never have an animal, a mineral, or any other definition, because the *C. luteata*, as named by Lindley, was an autumn flower, and this is the one you have flowering now, or some variety of it. I am also glad to find you include the lovely Indian *Crocopus* in your collection. They are exquisite things.—M. B.

5162.—**Odontoglossum eugenes** (*B. E.*).—I can scarcely tell what you really mean from the crippled and distorted flower you send me, but as you say you have had another similar one, I advise you to cut it, and to mark it as above, to which I think, perhaps, it may refer; if so, when you get it established you will have a grand variety. You say it was imported recently with *C. trinitatis*, and this species is supposed to be one of its parents; the other one is set down as *C. Deschampsii*, but it is a supposed natural hybrid between these two plants, and the characters of the parents of other genera have proved beyond a doubt. I shall soon, however, get some verification of these natural hybrid *Odontoglossum* when the seedlings raised by Mr. Sedley, Maynard, and some others when they open their blossoms. But you have a plant that will turn out a beauty, so take care of it.—M. B.

5163.—**Davallia pallida** (*A. Johnston*).—This is the name of your specimen marked with a 9; it is somewhat called *D. Monreana*; but Dr. Meislin told me before his last illness that he had clearly made it out to be this species, and so I have ever called it. It has an underground rhizome which brings young plants of this species to have very much the appearance of *Leucosticta lucifera*, but as it grows into fronds the fronds attain a size never seen in that plant. They are pale green and persistent, and I have seen a plant fully occupying a space it foot or more through; this will give one some idea of the size it will attain, and in such conditions it shapely looks majestic. It should be potted in good light-yellow loam, mixed with fibrous peat, chopped up with a spade and not sifted, mixed with a good bit of sharp silver-sand, the pots to be kept in being thoroughly well drained; and it requires very liberal watering during the growing season, and even in winter it will be found a thirsty subject. It likes also the temperature of a warm stove, and to be treated to a liberal amount of shade.—J. J.

5164.—**Insects and Cyclamen bulbs** (*Jan. Pike and John Colker*).—The insects attacking the roots of your *Cyclamen*, &c., are the grubs of the Black Vine Weevil (*Oryctes nasicornis*), and other species of the same genus. As far as I know there is no means of destroying the grubs but plucking them out from the roots of the plants. The weevils are nearly black in colour, and about half an inch long. They are very injurious to the foliage of various plants. They are very difficult to find, as they hide themselves in the soil, coming out at night to feed. Plants in pots should, when it is dark, be shaken over a white shawl, and then be carefully searched with a strong light. Plants grown in open borders are more difficult to protect from these beetles; but any stones or rubbish under which they might hide should be removed. There is another weevil belonging to the same genus, *Diorhynchus pilipes*, which is of a pale greyish-brown colour, whose grubs are quite as destructive as those of the species described above; the weevils generally make their appearance in May.—G. S. S.

5165.—**Cankerred Apple-shoot** (*Mr. Hopkins*).—The Apple-shoot you sent was certainly very badly cankered. Canker is rather a mysterious disease. It is generally supposed by having grown into the soil that does not suit them; but, according to Mr. H. Marshall Ward, who is one of our best authorities on the diseases, canker is due to local injury or destruction of the cambium, the outer layer of the wood (that just beneath the bark), which may be caused by a parasitic fungus, or by injuries caused by the weather or insects. Anyhow, as far as I know, it is incurable in most instances. In some cases much benefit has been done to the trees by taking out the soil near the growing roots and filling in with fresh soil. "The winged female" which you found on your Espalier tree is the wingless female of the Mottled Lumber Moth (*Hybernia defoliaria*). The caterpillars of the moth are most injurious to the young foliage of Apple and other fruit-trees; in districts where this insect is common, means should be taken to prevent the females (which are always wingless) from crawling up the stems of the trees to lay their eggs on the leaves. The best means of accomplishing this is to cut a band of some sticky substance, such as the Indian cannot crawl over, round the stems of the trees about a

foot from the ground. The sticky material should not be painted on to the bark, as that would be injurious to the tree, but should be placed on bands of paper not less than 8 inches wide, which are greased proof, and they should be so carefully fastened round the stems as to prevent any of the moths from crawling underneath. Various sticky compositions have been used, tar, cut-grease, and Davidson's composition, or a mixture of cut-grease, soft-soap, and train-oil. Whatever is used, care must be taken to renew it as soon as the composition ceases to be sticky enough to entangle the insects.—G. S. S.

NAME OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—*Araucaria*.—1, *Polystichum angulare proliferum*; 2, 3, and 4, Varieties of *Prinos acerrula cristata*; 5, *Sepidium hookeri*; 6 and 7, *Adiantum formosum*; 8, *Polystichum angulare*; *Wollastonia*; 9, *Davallia pallida*.—*J. Downing*.—*Catleya purpurea*.—*J. Maynard*.—1, *Cypripedium leucanum*; 2, *Brassia alba danica*; 3, *Laelia anceps* Hillman; 4, *L. Websteri*; 5, *Davallia elegans*; 6, *Idontosia aculeata*; 7, *Adiantum Willeanianum*; 8, *Diplazium laevis*; 9, *Aquarium vancouverianum*.—*D. Freese*.—1, *Adiantum triphyllum*; 2, *Adiantum*; 3, *Adiantum*; 4, *Adiantum*; 5, *Adiantum assaiense*; 6, *Adiantum amabile*; 7, *Adiantum hispidum*.—*Oliver Haywood*.—*Oncidium varicosum*.—*T. G. H.*.—1, *Niphobolus perkinsii*; 2, *Colybia unicornicra*; 3, *Phytolacca nigrescens*; 4, *Phacelia squarrosa*; 5, *Stenocoma aurita*; 6, *Woodia polystichoides*.—*T. Gibson*.—*Balanium culcitra*.—*A. B.*.—Single *Chrysanthemum Yellow Jane*.—*M. B.*.—*Cypripedium insignis*.—*P. Fane*.—*Eranthemum pulchellum*.—*John Thackeray*.—Also specimens. Though not often seen in bloom, it is not an unusual occurrence for it to flower.—*H. B.*.—*Chrysanthemum*; 1, *Potter Palmer*; 2, *Sofia Levant*; 3, *Hereward*; 4, *Alfred Sater*; 5, *Isle des Etalons*; 6, *Empress of India*.—*No Name*.—1, 4, and 5, *Speuchium insubricum*; 2, *Pteris cretica sublineata*; 3, *Adiantum gracillimum*; 6, *Pteris serrulata*; 7, *Lycopodium scolopendria*. In future please send better specimens.—*J. B. Lambey*.—*Chrysanthemum*. The blooms were in bud condition; however, they were sent in an exact name, whose names as follows: 1, *Muse C. Amphibius*; 2, *Decayed*, cannot name; 3 and 9, *Identical*, *Alfred Sater*; 4, *Viridul Morel*; 5, *Glorie du Fischer*; 6, *Jamur Sater*; 7, *Mlle. Lacroix*; 8, *Queen of England*; 10, *Probably C. Endrewood*.

Naming fruit.—*Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.*

Names of fruit.—*J. P.*.—Apple way be Wren Pippin, but specimen much shrivelled.—*J. Le Couteur*.—Apple White River main.—*W. A. A.*.—Apple; 1, *Warner King*; 2, *Royal Russet*; 3, *Royalway Magnum Bonum*; 4, *Probably Five-crowned or London Pippin*; 5, *Fruit shrivelled up*.—*M. M.*.—Pears; 1, *Bliss Moreau*; 2, *Year of Winkfield*.—*J. P. Winkfield*.—Pears; 1, *Phaeneton Duchesse*; 2, *Beurré Rance*.—*Everett Partridge*.—Now, on fruit sent all detached and mixed up so that we could not name them.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

H. B.—Apply to any dealer in artificial manures.—*Lily*.—Apply to Mr. T. Hancock, Art Nursery, Drington, York.—*J. S. W.*.—We know of no book that will help you so well as *GARDENING*; send us queries.—*Thos. Alderman*.—Apply to the Publisher at this office.—*L. H. Wharfedale*.—A pretty but not unusual form of *Chrysanthemum*.

POULTRY AND RABBITS.

Feeding fowls (*B. J.*).—In feeding fowls give them just as much food as they will pick up with evident relish, and to discontinue throwing down any as soon as they have had enough. The querist does not give his birds nearly enough to my thinking. A bushel of corn per week amongst eighty birds does not allow a very heavy quantity for each fowl; indeed, the latter amounts to only a little more than half a gallon per peal for all—a ridiculously small allowance. It is no wonder that the fowls are constantly hungry. If better results are hoped for, extra food must be given. Early in the morning the birds should receive an allowance of meal mixed with boiling-water, and fed as hot as the fowls will eat it. Then in the afternoon, just before the birds are going to roost, give an allowance of hard corn. On no account feed between the regular hours. It is this which makes fowls disinclined to work for themselves, but if you are ready to run after any one who chances to walk amongst them.—*G.*

Violas, Snowdrops, Winter Aconite, and similar dwarf bulbs, if you take care not to plant too close to the roots of the Roses so as to injure them, as the bulbs, take very little nourishment indeed out of the soil. The most beautiful garden I have ever seen for colour was planted with Carnations or Roses, both classes in distinct groups, and you may use also Tuffet Pansies, or such annuals as Mignonette. In many of the parks one sees the latter used, and nothing is sweeter and prettier than this old favourite.—C. T.

For autumn you might have the Autumn Greens in variety (*Sternbergia lutea*). The Chinoxoda (Glory of the Snow) is a charming thing in spring. Neither these or the autumn flowers mentioned above will hurt the Roses.—E. H.

"Tallynally" may safely put any bulbs among these, but I would only choose those coming into bloom early. By this means, will ensure the crop of them before the leaf of the Roses is too dense to allow of their fully being seen.—H. U.

5008.—**Baking for button-hole Roses.**—The most popular plants used for baking Roses are *Aitium cuneifolium* and *Asparagus plumosus*; but these require some amount of heat. I have seen very dainty button-holes of the Maloina and Roses, just a little of the bronzy-chocolate tinge of the former, to bring out the refined and beautiful colours of the flowers. Roses are always charming when their own leaves are used, and this remark applies to flowers in general.—C. T.

GARDEN WORK.

Conservatory.

The *Chrysanthemums* are now thinned out considerably. Lady Trevor Lawrence is a very useful white for Christmas cutting when cut down in June, and kept cool after the first frost. Good whistles are always in demand. The groups of *Chrysanthemums* gradually getting smaller, there is now plenty of room for other subjects. A group of cool *Orchids*, where *Orchids* are grown, will be a very attractive feature. Bulbs are now coming in plentifully, and good specimens of *Arum liliaceum* are very effective, and in the buoyant atmosphere of the conservatory are very lasting. *Urtica* or *Goniatum*, planted out in the border, soon make dense bushes which flower continually from October to March, when, if they are cut into shape, they may have all the summer to make an ripen growth. The *Genista* makes a good wall plant, and I have used it to form arches in the conservatory, with, with a little trimming and training, were very effective. One of the features of this class of plant, when set out in the border, is their exuberant health and freedom of blooming. The still *Coronilla glauca* is not a fashionable flower, but it is very useful at this season, nevertheless. *Camellias* are now very bright, and the old Double White is still one of the best for cutting; *Embellata alba* is also a good white. White *Azaleas* are now to be had in quantity where the plants have had their growth well ripened. *Deutsche Perle* soon opens its buds in a temperature of 60 degs. to 65 degs., and at this early season the flowers will keep a long time. The watering now will require judgment and care. Certain classes of plants require liberal supplies. *Chrysanthemums* and *Camellias*, for instance, must not be allowed to get dry, and weak stimulants may be given in plants coming into flower, or with many buds still to open. A night temperature of 60 degs. will now do very well. There may, of course, be a little fluctuation around this figure, but we will take 50 degs. as the minimum. The day temperature must, in a great measure, depend upon the amount of sunshine we are favoured with, as I should not recommend strong winds at this purpose, keeping in a way high day temperature. Chinese *Primulas* should be kept in a light position, and not watered too much. *Urticariens* will flower in similar conditions. *Bonariidias* should be placed at the warmest end. If starved the plants soon get shabby, and when that condition arrives better dry them off and cut down. *Poinsettias*, when they come to be effective, should be gradually ripened off by withholding water, and may then be taken back to the cool stove.

Unheated Greenhouse.

This house will not yet be without flowers. In spite of the one or two rather sharp frosts we have a few *Chrysanthemums* still in flower. *Chrysanthemums* are charming, and bushes of *Laurustinus* and the Naked-flowered *Jasminum* are as fresh as possible. Another useful little shrub is the *Andromeda forficunda*; the little white bell-shaped flowers are very lasting. There is a good deal of decorative value in the *Chimonax* family when grown under glass. If the frost comes very severe the pots must be protected with *Cocconut-fibre* or something else. Do not forget when the frost comes to stay for two or three weeks that covers on the upright glass and also on the roof will tend very much to the comfort and safety of all plants not absolutely hardy. Water, except for the *Laurustinus* and other hardy subjects, will not be much required.

Stove.

Demulrolium, *Cypripedium*, and other *Orchids* will be more or less in evidence now, and very charming they are, and in a well-furnished stove, with a night temperature of 50 degs. to 60 degs., there will be many other interesting things in blossom. The *Cestradendia* roses and *forficunda*, *Intars carnea* and *rosea*, *Flumbago rosea*, *Euphorbia splendens* and *Jacquinia*, *Begonia* in variety, *Justicia*, and many other things, both hard and soft-wooded, are now yielding blossoms for cutting and other decorative purposes. *Gloxinia* here, in many instances, started, and are now making leaves, and will shortly show flower in a warm, moist atmosphere. Watering is always a work of care at this season. Never water any plant without rapping the side of the pot. This is the gardener's best test when

in doubt. The condition of many things may be instinctively known without this test, but no one should water any plant about the condition of which there is the faintest kind of doubt without tapping the side of the pot.

Orchard-house.

At the present time the trees will be outside, and the house occupied with the *Chrysanthemums*; but these will soon be over, and after the cuttings are secured, and the plants cut down, the latter may be moved to a cool pit, and the house got into condition for the return of the Peaches and other fruits which are grown in pots. For the most part the necessary potting and top-dressing was done, or should have been done, in autumn, and before the leaves fell, and the roots will now be working into the new soil. It is a great advantage to do all this kind of work before the leaves have lost all their influence upon the roots, as the impulse then given will be continued steadily throughout the winter. Peach-trees and other fruit-trees in pots which are well managed should not require much pruning now. There will be the usual shortening of snags, and the removal or shortening of superfluous shoots. A good kind of manure through a lot of hoed-over leaves, things better than he found them, even though much is not required. After the pruning wash every part of the tree with an insecticide of sufficient strength to destroy all insect life.

Ferns under Glass.

Keep the plants free from dead fronds. The glass cannot be too clear over Ferns now, as although at the present time there is not much radical growth movement, the buds at the base will soon be on the move, and light is an important factor in giving them a good start. Young plants of the hardest Ferns in a pot-bound condition may have a shift now; but, as a rule, all may remain as they are for another month or six weeks without injury. Then the collection must be gone through, and whatever potting or shifting is required done before the leaves of Ferns about now, as a rule, are dried off. There are exceptions to this, like all other rules, but very few Ferns are the better for drying off. Maiden-hairs may occasionally be cut down, but the new growth will start away directly.

Window Gardening.

The main thing to keep in mind is to be ready for sudden frost, and to this end water should be sparingly used. By this it does not mean that only a little should be given, as all plants when watered should have enough to moisten all the soil, but no more should be given till the plant really requires it, whether that time remains a week or longer. Everybody has to make the best of their means about Christmas and the new year, and something may be done with hardy plants, such as shrubs, &c., with a few flowers in the salient points.

Outdoor Garden.

Cover Christmas Roses with hand-lights or cloches. The plants in dry borders are not flowering so freely this season in consequence of last summer's drought. Make new beds of July of the Valley. Work in plenty of laid-mould previous to planting, and mulch with rotten manure afterwards. Violets are not likely to flower so well this season where the water supply has been short, the red-spider having injured the lillage. A note should be made of these matters for future guidance. See that standard Roses with good manure, and newly-planted Roses with good manure, and give them a good watering. The ground should be well broken up to give them a fair start. Rearrange old shrubberies. Old overgrown Lilacs, Syringas, and things of like character, should be grubbed up, and young plants of better varieties set out in their places after the ground has been trenched up and manured. There is plenty of room for improvement in old places. This is not the best season for pruning flowering shrubs, as laid pruning now will cut away next season's flower buds. The best time to prune leafless flowering shrubs is just as the flowers are falling. The new growth will soon fill up, and will have plenty of time to ripen and produce blossoms. Bush or tree lilies are very ornamental now, especially if of large size. Time is required to produce a large bush, but when once established the growth of the green-leaved varieties is very rapid. They are easily propagated from cuttings. Seeds are of no use, as now, if not all, the seedlings will go back to the type. Manure the ground, and if there should be any vacant beds now. Fewer beds and always full should be the order of the day, and to this we are working round. A bed full of Wallflowers or *Brompton Stock*, the seeds for which cost next to nothing, are better than anything else. Then there are *Primroses*, *Tufted Pansies*, *Daisies*, *Forget-me-nots*, *Silenes*, and other things, all of which can be propagated at home to make the beds and borders bright in spring, when everybody is hungrier after flowers.

Fruit Garden.

Hurry up repairs in pruning, and apply a dressing to insects. Fresh time is cheap, and is not half enough used. Nothing stimulates a tree more than a dressing of fresh lime, where the bark has a tendency to Moss formation. Apply it when the bark is damp, so the most of it may stick. It will ultimately wash down to the roots, and so a double benefit will be obtained. In making or tying the branches of trees to wall or trellis leave room for the branches to grow. Much injury is done by light ligatures. Cut off suitable wood to form grafts. All who have a good collection of hardy fruits should do this, as if all are not required at home, there is always the chance of having the pleasure of supplying friends who have inferior cleared the soil, and the trees top-dressed, and all made ready for starting. Pot-Vines may be started at once with a night temperature of 50 degs. Figs intended to be forced early should be pruned, cleaned, and trained. If grown in pots, apply a rich top-dressing, or, if necessary, repot. Figs in large pots may be carried on for a long time with rich top-dressings and liquid-manure during growth, and when weakness sets in, prune hard back and reduce the roots and start again. Figs in a pot-bound state may have large slices made in the balls with a knife with advantage, as they soon make new roots. Keep full-grown succession Pines rather dry at the roots for a time to induce starting. If in pots, lifting the pots out of the plunging-bed will administer the necessary check to cause the fruits to start, when the warmth and moisture be applied again; but this plunging treatment must not be continued too long, or the fruit will be in colour. Most of the fruit trees are now in fruit, but do not overwater.

Vegetable Garden.

Hitherto there has been no stoppage in the work through stress of weather, and the winter Greens have profited by the mild weather to make a lot of growth, which in the event of sharp frosts will suffer considerably. To save the Broccoli in a season like the present they should be heeled in, and where this has not been done it would be wise to see to it at once. Autumn Cauliflowers and Broccoli have been very fine, and those still uncut must be protected when frost is expected, or they will be spoiled. Mint, Sorrel, and Tarragon are now required in a green state in good establishments, and to keep up a succession there must be a command of heat, whose relays of roots may be placed in as required. There must also be the means of protecting Parsley and Chervil to ensure a supply in the case of bad weather setting in suddenly. Do not overwater Lettuces in frames, or the leaves and hearts will rot. The demand for moisture in cold frames is now of the slightest, especially where air is not given freely. Celery and Cardoons must be protected from frost. Take up Asparagus roots for forcing in anticipation of frost, and lay their roots close together and cover with long litter, to be ready when wanted, so that there may be no break in the supply. When the new year comes in Asparagus may be forced in the open ground, if there is a good stock of fermenting materials. When grown in single rows trenches can be opened between the rows which are filled with manure and leaves, the row of plants being covered with movable boxes. The trenches need not be very deep, as the fermenting material may be built up above the surface by the sides of the boxes. Usually some soil is taken from between the rows for blanching purposes, and this can be levelled down again after cutting ceases. The advantages of this kind of forcing is it does not destroy the plants. After a couple of years it will force again if desired. E. Hobday.

Work in the Town Garden.

Many *Drechs* succeed fairly well in the atmosphere of moderate-sized town, or in the suburbs of London, &c. Indeed, I know more than one grower who manages a selection of these interesting and popular plants with really wonderful result in quite the heart of the town. Such kinds as *Oenothera*, *Alexandria* and others, *Drechs* of various sorts, most of the *Cypripedium*, and notably the beautiful *Colony* crystals, which flowers at mid-winter with a very moderate amount of warmth, thrive with a reasonable amount of care, in even the most unlikely places. The majority of those mentioned, as well as many others, succeed best in what may be termed our "intermediate house"—that is to say, in a house or pit where the heat seldom falls below 50 degs. in the winter time, and never below 45 degs., rising to 55 degs. or 60 degs. during the day, and with a summer range of 60 degs. In 50 degs. or so. A constantly humid atmosphere is a necessity—at any rate, during the whole of the growing season—and ventilation must be cautiously and, as a rule, sparingly given, and with a due supply of water at the root, the failures will be few. Consequently, the plants associate well with the more tenacious description of Ferns, *Painis*, and other fine foliage plants—*Drechs*, *Gloxinia*, *Goniatum*, *Indica*, in a town garden, but of this class of plants, if carefully tended, will often give more satisfaction than a greenhouse proper. Now that the plants are, for the most part, at rest, is a good time to buy *Orchids*, and then they become accustomed to their new surroundings and treatment from the very commencement of growth. On the other hand, what are known as "hard wooded" plants, including *Hyaths*, *Jornalis*, *Chorozenus*, *Apexis*, *Frostemons*, *Genetia*, *Thibaudias*, and others, which were far more commonly grown half a century ago than now, do not as a class, thrive at all well in the murky atmosphere of a large town or city, and should consequently be avoided. Oddly enough, *Camellias* are however, capital town plants, and so are the charming and most useful forms of *Epicaris*, with *Boutaridias*, *Myrtles*, and even the quaintly pretty *Australian Correas*. Common *Primroses*, grown in pots, are now in full bloom in a few cases, and give an idea of the possibilities of spring. Violets, however, are seldom in town gardens, both indoors and out, and the same may be said of lilies, while *Pansies* do not thrive as in pure country air and soil. Seed catalogues will soon be coming in, and making out the seed order for next spring is a nice occupation for one or two of the long evenings. Always depend chiefly upon well-tested favourites, with a few small packets of something new by way of trial only. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from December 23rd to December 30th.

Noted another batch of *Tuberose* and plunged them in the peat-moss-fibre to make roots in cool-house. Moved plants of various kinds to forcing-house for early flowering. Filled a small pit with Strawberries in pots. The night temperature will be about 50 degs. Put in more cuttings of *Chrysanthemums*. All those *Chrysanthemums* going out of bloom have been cut down, and many of the duplicates have been thrown away, as they will not be required if it is useless keeping them. If a wet day comes the pots will be watered and packed away till next season. Pruned, cleaned, and trained Peaches in a late house. Burden inside have had a good soak of cool-water. It is stimulating without encouraging gross growth. Looked over the choice alpine on rockery, and placed a thin mulch of *Cocconut-fibre* round the roots of a few which appeared to need a little protection. A few things have been sheltered by placing cloches elevated on stones to keep off heavy rains, and yet permit of a free circulation of air. Alpines in pots, of which a few are grown as duplicates, have been covered in a bed of ashes up to the rim in a cold pit. Lights will be drawn off on every favourable opportunity. Pruned and trained hardy climber-plants on walls. Tender things, such as *Ceanothus* have been left unpruned till spring. Herbaceous borders have all been mulched with short manure. Finished pruning hardy fruits, except Peaches, Appricots, and Figs; the latter are at present covered over with Spruce branches, and will be cut off till the end of the month. Looked over fruit-stove to remove decayed fruits. Made fresh manure pits and Brans on south border.

* In cold or northern districts the operations referred to under "Garden Work" may be done from day to day for a fortnight or three weeks before the weather becomes so cold as to render it inadvisable.

Planted more Lettuce and Cabbage-plants. Made up new Mushroom-beds. Cleared out one exhausted bed and filled space with Sea-kale-roots. Planted a house with Cucumbers to come in about next Easter. Looked over a house now in bearing to stop and regulate growth; very little knife work is required where the plants are looked over once or twice a-week. Plants which are permitted to run will not bear so freely as when every shoot is pinched one last beyond the fruit; but every shoot which shows will not be permitted to remain on now. Moved a few late Peas to a temperature of 60 degs. to bring up flavour and make the flesh more melting. Spent half-day in shading line over Apple-trees in orchard. More lime might be used, or rather it might be used more frequently; it cleanses and brightens the bark. Made up a range of hot-beds for Asparagus, Potatoes, and Horn Carrots. Trenched and manured a piece of ground for Onions next season. Turned over compost heaps. Moved a lot of early Broccoli to a deep, cold pit. Shall cover with manure and dry litter should frost occur. This pit will secure a supply for a long time, as in many plants the insects are only just forming, and as the check given has been slight the plants will continue to grow, and they may be cut as required. Put new stakes to standard Rows where required. Re-planted Box-edges where it had become a little patchy from using weed-killers. Rain came unexpectedly shortly after the weed-killer was used and the Box suffered in several places. Unruffled Peaches on walls. Pruned Laurels and other evergreen shrubs, where used for undergrowth, to keep bottoms well clothed with leaves. When permitted to grow up the bottoms get thin.

FRUIT.

GOOD MARKET PLUMS.

WITH me, in the South of England, the following varieties are generally the best—viz. Rivers' Early Prolific, one of the best of very early Plums, being fully ripe at the end of July on a wall, and very little behind this on bush-trees. Early Orleans, another excellent early sort that succeeds well as a bush tree, very prolific, and good for any purpose; makes a good succession to Rivers' Prolific. Victoria, too well known to need any description, is the very best Plum in cultivation for cropping and for any purpose for which Plums are grown; as a cooking Plum it has no rival, the flesh being thick and the stone small, and when fully ripe it is also a very excellent dessert Plum. Jefferson, a beautiful dessert fruit, very rich in flavour, and, I think better than bush or pyramidal trees than from a wall. Pond's Seedling, one of the largest of Plums, with very handsome fruit, excellent for kitchen purposes. Coe's Golden Drop, one of the finest late Dessert Plums in cultivation, being most delicious in October, as it will hang until partially shrivelled on a wall, quite ripe to the end of October. Green (age is still one of the best flavoured of all Plums, and a good bearer, and Gisborne's (here figured) is a capital medium-sized kitchen Plum, of a greenish-yellow when ripe. The tree is an early and abundant bearer. H.

Plum "Gisborne's." Engraved from a photograph sent by Mr. J. Mayle, 133, Parliament street, Derby.

Staking fruit-trees.—It is quite true that a lot of fruit-trees are planted and not staked. More is the pity, because it is not possible that standard trees can stand erect with but a mere handful of roots in some cases to balance the head. I make a practice of staking all standard fruit-trees the same day that they are planted. Some persons, I know, leave them until a favourable opportunity occurs. In the meantime most likely a strong gale of wind springs up, accompanied with heavy showers. No matter how carefully the roots may have been spread out when planting, it is impossible for them to remain so for any length of time when the trees are being blown about by the wind; some, perhaps, are blown quite down. The old-fashioned plan of placing the stake close to the tree, or at least an inch or so away, then hiding a piece of sacking or straw around the tree-stem, to be after secured to the stake with the familiar rat cord, is a plan not to be recommended nowadays. There is nothing to equal a wither made from a sapling; either Hazel or almost any kind of coppice wood that will twist will answer the purpose better than the shoots of the common wild Guelder Rose, which many persons in the

country call Whitewood. The advantage of these withes is that the stake can be kept at least 6 inches from the tree, which effectively prevents the stake rubbing the tree, as in the case when rat cord is employed. The stake is driven firmly into the ground, a thick wad of straw is placed on each side of the fruit-tree-stem, to be made fast to the tree by fastening the wither around it by means of the loop which should be made at the end of each. A turn is then taken round the stake, another round the tree. The end of the wither is then made fast half-way between the tree and the stake by winding it round the parts which stretch from tree to stake; the end of the wither is tucked through the twisted parts and made fast. It is not possible for the tree alone to be moved by the wind; therefore, if the stake is driven firmly into the ground, the tree must be secure. These withes last a year, the stake, too, as a rule. Simply renew the wither and the trees are again made secure. In all country places these withes can be had without much trouble, but, failing them, No. 8 galvanised wire would answer very well. Sometimes the ties slip down the stem of the tree and the stake, owing to the constant pressure put on each during windy weather. A tack into the stake will remedy this.—H.

STARVING FRUIT-TREES.

THE return of the winter, when pruning and manuring is usually performed, offers a favour-

able opportunity for calling attention to the fact that fruit-trees are starved in many ways, besides that of withholding the necessary applications of manure, without which it is impossible for any time to keep on producing heavy crops. It has been proved over and over again that cropping Vine-borders is ruinous to the Vines, and not a profitable proceeding to the owner, for the simple reason that more is lost in the crop of Grapes than is gained by any produce that can be grown on the border, and this is applicable to other fruits as well, and it may be laid down as a general rule that as the roots will extend quite as far from the stem as the top of the tree reaches in height that this distance should be kept sacred to the roots, and mulched and tended like a good Vine-border, if fruit of the finest is to be grown. Yet what do we find, as a rule, in small gardens? The vegetable crops are planted right up to the stems of the trees on the plea that they cannot afford the space necessary to give the fruit-trees a chance of having their surface-roots undisturbed, and it is no uncommon thing to see the soil being dug over when the tree needs every root to swell up its crop, and the best surface-roots are cut off or rendered useless by reason of being mutilated when they ought to be undisturbed. Some vegetable crops are not so bad as others, but almost any of the Cabbage tribe are so strong rooting and gross feeding that they will soon starve any fruit-trees into a weakly, debilitated state, from which it is no easy matter to recover them. If you point out the plan of starving fruit-trees to the owner, the probabilities are that you will be met by the reply that it is done in much larger

gardens than theirs, and must be right, but the fact of its being done by people who ought to know better proves nothing more than its being an established custom that takes a long time to overcome. Mixed flower-borders have much to answer for in starving fruit-trees; if you pass along some garden walks you will note that fruit-trees, either as espaliers, bush, or pyramids have been planted a few feet from the edge, and flowers of some kind have been planted to make the garden gay; but it is all at the expense of the poor fruit-trees, for, although they grow away finely together for a few years, it is only a question of time when the strong herbaceous plants will get the mastery of the fruit-trees. It seems odd that a tree should be starved by a plant, but it is all a question of rooting power, and a bed of Chrysanthemums under an Apple or Pear-tree will soon starve it to such an extent that the fruit will be useless. If you wish for fruit of the finest that can be grown, plant your trees on good soil, and keep it solely to their use, for it is the worst economy to attempt to grow two crops on one plot of land, and to do this properly the fruit garden should be quite distinct from the flower or vegetable garden. If intermediate cropping is done at all it should be at such a respectful distance from each other that the roots of the flowers or vegetables cannot rot the fruit-trees, or assuredly the fruit-trees will get the worst of the contest.

JAMES GROOM, Gosport.

5132.—Forcing Strawberries.—The demand for forced Strawberries has of late years been very erratic, and the fancy prices generally fall to those who are close to and understand the market. Of course, the early fruits, if good, fetch the best price, but they are perishable goods, and want very careful packing, and should not be too ripe before gathering. The same thing depends upon what variety they are. For sale large fruits are best. Good British Queen always sells well. Try and find a customer before the Strawberries are ripe.—E. H.

— If you can get the fruits ripe towards the end of March or early in April, you may possibly make 8s. to 10s. per pound of them; but to do so requires a lot of heat and great experience and skill, while the plants will only produce a few fruits apiece, and the right sorts must be employed. Much depends, too, upon the size, quality, and colour of the fruit. To force them thus early the plants ought to be started very shortly now; but you must not push them very hard, or give too much water, until the flowers expand.—B. C. R.

5125.—Planting a Vine.—Plant the Vine early in March, when the buds are moving. Drain the tub by putting from 4 inches to 6 inches of broken bricks or other rough material in the bottom. The soil should be old rotten turf and a little old manure, mixed with a little bone-meal or Thomson's Manure. The Patent Silicate Manure is cheaper, and Vines do well with it. A couple of pounds may be mixed with each bushful of soil.—E. H.

5120.—Best Raspberries.—Carter's Prolific and Baumforth's Seedling are excellent varieties. Both crop freely, and have a good constitution. If an extra large fruited variety is preferred, cut out the latter and substitute Northumberland Fillet.—S. P.

— A splendid Raspberry—profitable, tree-bearing, and producing large fruit—is Superlativo, and this should certainly be one, whilst the others select either Baumforth Red or Red Antwerp, as both are good.—G. T.

— Fastoll, though smaller than some of the more recent introductions, is a very free bearer, and is still largely grown. Hornet, Norwich Wonder, and Superlativo are large-fruited kinds.—E. H.

5107.—Grafting a Cherry-tree.—Cherry-trees are generally budded in July or August, but they may be grafted early in April, when the sap is flowing freely.—E. H.

5090.—Rats in a garden.—M. L. Williams should write to McDougall & Co., Manchester, and ask them for their preparation for rats. The next step will be to find out the rat-holes, and apply the preparation as directed. There is really no excuse for those who are tormented with rats in gardens, when, as in the present case, they seem to harrow in the open ground. It is when they take up their quarters in trouble-free haunts, and drains that exterminating them becomes a serious matter.—D. W. P. C.

THE KITCHEN GARDEN.

LATE POTATOES.

"W. H." and "R. S." enquire as to the characteristics of the Scotch Champion Potato, and also ask for the names of other good late kinds? In general qualities the first named (see illustration), when true, comes between the Scotch Regent and the Irish Rock, embodying the good flavour of the former and the hardy constitution of the latter. Like other Potatoes, the eating quality varies much, according to circumstances as regards soil, climate, and cultivation; but it may be safely classed among good table sorts. Occasionally, when the locality and season are alike favourable to its development its table qualities are quite first-class. The Champion is a strong, rank grower, and should be allowed a fourth more space between the rows and sets than that which ordinary kinds require in planting. It is, perhaps, the latest field Potato to ripen, the haulm remaining fresh when that of all others is withered; it should, consequently, be planted earlier than is usual for late sorts generally in order to do it justice. It will grow and yield remarkably well on poor soils where other kinds would not succeed, and, altogether, is to be highly recommended for a main crop in every garden and farm where large breadths of Potatoes are grown. It cannot, however, be too prominently kept in view that, to fortify its disease-resisting properties, and also to secure at their best its other good qualities, a thorough change of seed should be made each season. Other good late kinds are as follows:—Magnus Bonum, Danbar and other Regents, the old Pink Eye, a capital Scotch Potato, and Schoolmaster.

KITCHEN GARDEN NOTES.

At this season of the year draining, trenching, where it may be carried out, the turning out of old rubbish-heaps, and turning coarse refuse may be attended to. Burnt refuse, of which there cannot be too much in any garden, is a most valuable fertiliser, as well as a capital preventive against insect pests, especially those of a root-eating nature. Instead of allowing all such coarse refuse to lie in a heap to decay, and perhaps be an eyesore as well, the quickest and best method is to burn it, not only to get it into a smaller compass, but for its valuable properties when so reduced. For heavy soils its value especially cannot be too highly recommended for pointing into the surface immediately preceding cropping.

Drainage.—If the soil is to prove productive it must be in an efficiently drained state, so that aeration may follow, as without this the crops cannot thrive. A heavily drained soil on account of its richness attracts frosts, especially late spring frosts, which often prove so destructive to the tender crops in low-lying positions. As a guide to go by, trial holes should be dug 2 feet or 3 feet deep, and if water collects in these it is quite evident that draining is necessary. Draining need not be a costly undertaking—that is, if there is an outlet for the water as it collects in the drains. To gauge the number of drains required it is better to lay out a certain number first, say 16 feet or 20 feet apart, and upon the completion of these other test holes should be dug intermediate between them, and if the water stands in these instead of draining away, it is evident that more are needed. The drains should be cut straight, taking out the soil with proper draining tools, commencing wide at the top, at least, in comparison with the depth of the drains, tapering down to there being just room to lay the tiles. This narrowing down is very important, as if the bottom should be wider than the tiles these latter roll about and cannot be properly fixed in their places. All cross drains should run into a main drain, which should be lower than the rest, and have an outlet to drain the water right away. The drains are best left open until the whole are formed, so as to note more clearly the drawing off of the water. When all is ready, a layer of ballast or small chinkers should be first placed over the tile before filling in the soil.

SOIL-BURNING.—The benefit of burnt soil is well known. Of course, this has reference to clay land, which often needs some such addition. Hard-burned material is of little value, excepting for ballast. Do not attempt large heaps, as these are the more likely to become hard-burned. Small heaps are the best. To proceed with the work first prepare a fire with small coal, and when well alight this will act as a feeder to the smaller fires. A ring of clay should be formed about 3 feet over, and within which place the fire, taken from the larger fire prepared for the purpose. When a body of fire has been formed draw some lumps of clay around, sprinkling small coal amongst them,

Potato "Scotch Champion."

and as these become alight add other clay and small coal until the heap is formed. This may be about 3 feet in height, which is quite large enough for garden purposes on a small scale. If so desired the heaps may stretch out to several feet in length. No chimney is needed, as this would defeat the end in view, but if at any time it should burn through at the sides this must be promptly put right again. Directly the heap is sufficiently burned it must be quenched out.

CLEANING OUT RUBBISH-HEAPS.—When the ground is frost and snow-bound this is good work. Not that rubbish-heap material forms very good manure, but it is useful for heavy land, opening it up and adding humus, which this class of soil is so deficient in. It should be well worked over, forking out all the coarse refuse and burning it, returning the ash to the bank. Some freshly slaked lime may also be added, not merely for hastening decomposition, but for the destruction of the pupae and larvae of insects. After adding the lime allow it to remain for a week or two, afterwards again turning it well over. This material comes in very well for dressing ground intended for Potatoes.

5104. — Size of Tomato-house.—The length of a house for Tomatoes may be anything from 10 feet to 12 feet long up to that of Mr. Ladd's huge structure at Swanley, which stretches out to no less than 680 feet, though generally speaking the larger the better, as Tomatoes thrive best where there is plenty of space and air. As regards the width I consider that from 20 feet to 25 feet, or even 30 feet, is better than less, as it permits of two pathways being made, with two narrow side beds or borders, and one wide central one, and in this way one can get in among the plants better to train and trim them, or gather the fruit, while more light and air is also admitted among the plants. Again, a Tomato-house should be moderately lofty, for plants of most varieties will attain a height of 8 feet to 10 feet, or more, during the season, and on this account also it is better to be comparatively wide.—B. C. R.

—If profit is the main consideration the larger the house the better, as a large house can be built cheaper in proportion to size than a small one. A useful size would be 24 feet wide and 100 feet long, 8 feet to eaves, and 14 feet to the ridge. A path should run all round the centre bed may be 10 feet wide, and the side beds 6 feet.—E. H.

5114. — Growing two crops of Tomatoes.—You can certainly do as you suggest and

by taking the cuttings early—say, in May—and growing them on in 6-inch or 7-inch pots outside, and planting them in the houses directly you pull the first batch out there should be a break in the supply of not more than two or three weeks. Plants from seed sown early in January ought certainly to produce ripe fruit early in May, if kept moving on all the time. But by means of judicious "feeding" the same plants may be kept on fruiting right through until the end of October at least, especially in moderately lofty houses, such as these. Not long ago I saw a lot of plants that after fruiting from the beginning of May until July, and having reached the top of the house, which was low, were untied, bent down at the bottom, and then trained up again, and were thus kept going until the end of October—with plenty of nourishment, of course. Except in the depth of winter the plants do better planted out than in pots, while the labour of watering is also vastly less. After the end of October a good deal of heat is necessary to ripen Tomatoes properly, though it might be just managed in the smaller structure, which I imagine would be warmer than the other. A batch of late Chrysanthemums would probably be more remunerative on the whole. When cutting old plants down, the best way is to secure a young growth or two from the base previously, then cut away the old stem, and with a genial temperature and a light dressing they will grow away all right.—B. C. R.

5137. — Culture of Seakale.—Early in March is a good time to plant the roots. Strong plants can be bought for about 12s. per 100. These would give a supply of Kale the following year. Smaller ones would do, but more time would be required to have them ready for forcing. Raising a stock of plants by sowing seed in April is very often practised. This is the cheapest way; but two years are required before satisfactory results are obtained. If this latter plan is adopted sow the seed in shallow drills 15 inches apart. The year following treat the roots as advised subsequently. Seakale is a very accommodating vegetable as regards the soil. It will succeed in any good garden soil, provided it is deeply dug and liberally manured. Heavy soil should be prepared at once, so as to be in good order by the time planting is done. Trench the ground 2 feet deep, leaving the clay at the bottom of the trench and retaining the top soil in its present position. Work in as much decayed vegetable refuse and road-grit as is possible within 1 foot of the surface. When the roots are received early in March cut off the crown just below the junction where the leaves spring from. If this is neglected the roots will throw up a truss of known from each crown, and the development of this will interfere with the future crop. The whole energy of the roots should be concentrated in the free growth of leaves and a crown in the centre, from which the succulent leaves that are edible the season following are produced. When the crown is cut off, two, and sometimes more, shoots spring from just below where the severance took place. These growths should be thinned down to one, choosing the straightest, of course. Plant the roots in rows 18 inches apart and 15 inches in the rows, if it is intended to take up the roots for forcing in the greenhouse, stove-hole, or any such building that is fairly warm and can be made dark. If the roots are to give their produce upon the ground where grown by covering them with pots and manure, three roots should be planted anglewise, 6 inches apart, allowing 2 feet 6 inches between each clump. In planting it is a good plan to fork the ground over again, leaving it loose when finished. Cover the heels with 2 inches of soil. The ground must be kept free from weeds during the summer, and constantly stirred with a Dutch-hoe. This accelerates growth, and the more this is encouraged the better are the prospects of success.—S. P.

5109. — Growing Mushrooms.—To every five barrowfuls of fresh stable-mannure, after the longest straw has been shaken out, add one barrowful of sandy-loom, and thoroughly blend the whole together. It will be better to collect sufficient to form a bed at the same time, and when the heap has got warm turn it over and intermix, and make up the bed, building it so that the size and depth of the bed should be greater if made in an unshaded building than where artificial heat is used. If made against a wall in a cellar a good width will be 3 feet,

15 inches deep at the back, and one foot at the front. When made on the floor of the building, make the bed in the shape of a ridge, 3 feet wide at the base, rising to 2½ feet, the sides being made round. This gives a good deal of surface for the production of Mushrooms, and such beds retain the heat a long time, and are easily covered should covering be necessary. Bury the loam, then there is not much danger of overheating, and the beds are more lasting, and time is saved in turning and fermenting the manure by the old system. When the temperature of the bed is steady at 80 degs. to 85 degs. it may be spawned. This is usually done by breaking up the spawn into pieces about 1½ inches in diameter, and placing them just under the surface of the manure about 9 inches apart, all over the surface of the bed. After spawning make firm again, and when the spawn is running freely place 1½ inches of sifted loam over the surface of the bed, and beat down flat with the spade. A light covering of litter will check evaporation, and if the peat declines too fast the covering may be increased for the purpose of keeping in the heat. The spawn must be good, and if several beds are at work in the building at one time there will be warmth, except in severe weather, without fire-heat; but it is always desirable to have some means of heating, as Mushrooms cannot be grown in a lower temperature than 55 degs.—E. H.

4927.—**Early Tomatoes for market.**—Respecting "Mr. H. Drury's" reply to the above query, I have no doubt but that this gentleman's seedling from Horsford's Prelude is a like variety to the well-known and highly-esteemed variety Conference, which latter was raised from Prelude. I grow Tomatoes by the ton, and have them going all the year round. I also give the greater portion of new varieties that from time to time appear a trial, and I could a tale unfold concerning many of recent introduction, which would not, I fear, please the raisers. There is, however, a variety which was sent me for trial by Mr. E. C. Ravenscroft, of Hield, Crawley, Sussex, named Hield Gem, and I have no hesitation in saying that it is the very highest type of excellence in the Tomato way that has yet come under my notice. The plant is a very close grower, and appears to do even better in pots or boxes than planted out. Even now (December 7) I have plants on slight bottom heat not 3 feet high, with four and five trusses—these not 6 inches apart—setting freely. The fruit is borne on single and double-branched racemes, bearing from five to nine fruits each, flat-tish round in shape, weighing from 5 oz. to 8 oz. each. The colour is grand, being a glossy brilliant crimson, and the fruit is solid and weighty. The flavour is not by any means the least point, and I can say that it surpasses all that I have ever tasted, and for eating in a raw state its refreshing sub-acid flavour is pleasant indeed. In addition to the above-named qualities it is early and comes on very quickly. In April this year I cut from this variety a few days sooner than from Sutton's Earliest of All, and the appearance was so far superior to the latter that I intend planting Hield Gem in all my early houses the coming season. I believe it is a seedling from Conference, crossed with a large-fruited American sort, and much resembles Conference in foliage, but of thicker substance, and the leaves have the peculiarity of standing out from the stem in a stiff horizontal position. As regards raising Tomatoes for early work so as to have fruit ripe in April, seed should be sown at once on slight bottom-heat, and when well up removed to a shelf near the glass in a temperature from 55 degs. to 60 degs.—E. F. L. S., Jersey.

5093.—**Seaweed as manure.**—In reply to this question, allow me to say that Seaweed is one of the very best manures that can be used, not only for the purposes named of a top-dressing to Seakale and Asparagus-beds, but of which naturally grow by the seaside, but also for the general run of kitchen garden crops. In this locality it is used extensively, as we have a good many allotments let to cottagers favourably situated for collecting Seaweed, as the tide ebbs and flows in creeks close by, and leaves a great quantity of Seaweed, that is collected at low water, and dug into the land when quite fresh, and I have been assured that not only are the crops finer than where ordinary manure is used, but that root

crops, such as Carrots, are much less attacked by wireworm, and the slugs do not appear to like the saline properties of the Seaweed. As a dressing for flowers it is highly spoken of, and on light soils it retains the moisture for a long time.—J. G., Gosport.

5053.—**Replanting Seakale.**—You may safely transplant this now, or at any time, up to the date it commences to grow, but, except for forming new beds, it is not necessary to transplant Seakale, for if it is strong it can be lifted and forced in heat, or covered with Seakale-pots, and then with fermenting material; but if the object is to form permanent beds for forcing in the open air it is now a good time to perform the work. Any good kitchen garden soil will grow Seakale, although it naturally grows in loose, shingly soil by the coast. Young one-year-old plants are the best for planting to form permanent beds. Seakale is readily increased by pieces of the fleshy roots cut into sets, and allowed to form crowns before planting in open air in April.—J. G. H.

5131.—**A large Tomato.**—Yes, there is a large-fruited variety of this name, but it is a great coarse thing, useless for market purposes and but little good for anything but curiosity. From what I have seen of it I would not give it house-room.—B. C. R.

ORCHIDS.

CATTLEYA WARSCEWICZI.

In reply to several enquirers, "B. C. D.," "H. R.," &c., this plant is doubtless more familiar to some Orchid growers as *Cattleya gigas*, a name it obtained in Belgium when first introduced in a living state, and before it was recognised as being identical with the *C. Warscewiczii*, of Reichenbach, which had been

Cattleya Warscewiczii.

discovered by the grand old collector, whose name it bears, as far back as 1848. It is a native of the province of Medellin, in New Grenada, where it is said to grow upon the branches of the forest trees, which are well exposed to sun and air, and which grow in the neighbourhood of water. It is one of the noblest-growing and most magnificent *Cattleyas* whose bloom that has yet been discovered, but it has not hitherto proved to be so free

flowering as many others of the *lanceolata* section. Neither is robustness a sure indication or guarantee of flower to follow, for I have seen very many more plants blossom which had made medium-sized bulbs than I have of the very large and robust form. It has stout pseudobulbs, which support a large single oblong-ovate leaf, which is very thick and leathery in texture and deep green. The scape (see illustration) rises from between an oblong spathe and bears from three to five flowers, which measure from 7 inches to 8 inches in breadth and some 9 inches or 10 inches in length; sepals and petals soft-rose colour or rosy-ruddy; lip very large; the sides erect, rolled over the column; the front part large and spreading, crisp at the margin, and of a rich purplish-crimson, flushed with violet in front, and bearing an eye-like blotch on each side of the throat, which is usually some shade of yellow. It appears to generally flower during spring and summer, but I have seen it blooming in November. The variety *Sunderiana* is found in the district about La Palma, and affects the same positions as the typical plant. The large spreading front lobe of the flower is rich purplish-tinged. Its treatment should be the same as that so often recommended for *Cattleyas* of this section, but it appears to enjoy a slightly higher temperature than most of them. M. B.

ONCIDIUM FLAVUOSUM.

In reply to the earnest entreaty of "Orchid," I appeal the following reply, also to the appeal of "A Perplexed One." Both my friends appear to have succeeded in a fair way with the cultivation of this *Oncidium*, as the first-named one has the plant now flowering. My other correspondent has it showing flower, but one of his perplexities lies in his finding some buds in the morning eaten off and lying upon the stage, and he has kept a careful watch and he does not think there is anything to eat them off in the two houses. Well, that may be all true enough, but my friend says nothing about the cockroaches. Has he, too, kept a careful guard over these pests? If so, why then I give his problem up; but if not, say about the extirpation of the cockroaches speedily. It is not often they trouble themselves about such an Orchid as *Oncidium flexuosum*, but generally select some finer and better thing, some plant that the owner sets more store on. Now at once get some phosphorus paste and put it down on and about the plants; also search and look in any and every empty pot there is in the house, go carefully through your plants hanging in earthenware baskets, and all those occupying standing pots, especially those with slits or openings in them, and dip them carefully and thoroughly, and any cockroaches that are dislodged kill by crushing them under your foot. It is quite astonishing what destruction is wrought by these things, when one only has a few flowers as at this time of the year, which perhaps would not be noticed in the fuller flowering season, or it would not give so much concern, while the enemy is growing both in size and numbers. Now for my friend "Orchid," and his entreaty. He says his plant is flowering, but that it is bent in what I used to call a sprawling manner, and the roots from the bulbs spread out into the atmosphere. When these plants cease repotting, should he put the roots down into the soil? Well, no, I should take a fair-sized bunch of wood and put into the pot with the plant, and so bring it upright by tying it with lute, and allow the roots to be quite free if they so liked, and when I repotted it still allow the roots to rove at liberty, if they feel so disposed. I never knew the roots of *Oncidiums*, *Cattleyas*, or any other Orchids to take kindly to the soil into which they were forced. Train them over the soil and give them an opportunity of going in if they choose, but do not hurry them by force. MATT. BRAMBLE.

DENDROBIUM KINGIANUM.

"BERMERTIN" asks for the habitat and right treatment of this pretty little Australian *Dendrobium*. I have had some large specimens of this species, but many of the Orchid growers of the present day have not heard of the plant, and if they had seen it, they may have

not seen it, and therefore have no idea of what it is like. This Dendrobie was discovered by Bidwill in South Queensland just about fifty years ago, and sent to Kew, and named by him in honour of Captain King. The plant is very distinct in growth, which makes it all the better remembered, being erect, with the bulbs clustered. These are each about 3 inches high, swollen at the base, becoming smaller towards the top. Upon the top are borne the leaves, which are usually in pairs, though sometimes more than double that number are found on them, and these are of an oblong-lanceolate shape, and thick and leathery in their texture. They are persistent, lasting for several years, the colour being of a rich deep-green. The raceme comes out from the top of the stem between the leaves, and is slender and free-flowered, the flowers being about an inch across, and of a dull purple shade of colour, varying somewhat in different individuals, but in none so much as to make it a showy plant, although it does belong to the Speciosa section of the genus, to which such kinds as *D. bigibbum*, *D. Phalenopsis*, *D. laminum*, *D. superbiens*, and several others that could be named also belong, and these are fine ornaments in our stoves. But to return to *D. Kingianum*. The flowers last a long time in perfection, and thus tend to make amends for other shortcomings, but I recently saw in Mr. Smee's garden a fine white form with much longer spikes, having racemes about a foot in length, and bearing many pure white flowers. It is called album, and is very well named. There are other forms with whitish flowers, but near the typical plant in size and in the length of raceme. Now, a little about the culture of this plant, which may be grown on a block of wood, but this is only in the young state, for this its tufted habit suits it capitally. In a pot it succeeds well if the receptacle is well drained, keeping the plant well up to the glass in order that it may have the full benefit of the light and all the sun that shines. I have, and many others besides me also have, kept these plants cool, in fact, quite cold, because they come from Australia, but we have found by experience that this was very wrong, and where we have had the plant to thrive the best was in the Cattleya house. Pot in good peat-fibre and chopped Sphagnum Moss, and rest the plants in the temperature of the cool-house. They bloom during the winter and early spring months.

MATT. BRAMBLE.

5128.—**Orchids for a cool greenhouse.**—The following will succeed well in a cool greenhouse, and the best of all for the purpose is *Cypripedium insigne*, which produces a wealth of bloom at this season of the year. It is cheap, easily grown, and will thrive well in an ordinary greenhouse. It is a native of Sylhet, and there are many varieties, *Mauici* being one of the principal, but if you get the ordinary form it will suffice at present. During the summer the plants require no artificial heat whatever, and Orchid growers, as a rule, keep them in far too high a temperature. The flowers of the *Lady Slippers* last long in good condition after being gathered fully three or more weeks, and are proof against fogs, which is a very important point in your case, as you live in a town. *Adiantum* is a useful species. It is a compact growing, ever-green kind, the flowers bright orange-scarlet in colour, and blooms freely in the autumn and early spring, when it makes a bright show in the house as the colour is so distinct and vivid. It also lasts a long time in beauty. *Bletia hyacinthina* has rosy-purple flowers, requiring a good loamy soil and plenty of water during the growing season. *Calathea Veitchii* produces

racemes of bright-rose, and requires more heat than the others mentioned. It is not very difficult to grow, and produces its scapes from the base of the pseudo bulbs without leaves. You may also have *C. vestata*. *Cattleya Trianae* is a lovely Orchid, and suitable also for a cool-house as such *Odontoglossum* as *O. crispum* or *O. Alexandre*, which are really the same, *O. Pescatorei*, and especially the cheery little *O. Rossimajus*, which varies in colour, sometimes with more rose on the lip. The sepals are, however, as a rule, pure-white, also the petals, except that the latter are barred with crimson-chocolate, the lip being white. The flowers last a very long time in full perfection. *Cologyne cristata* is one of the most popular of all Orchids, its flowers are pure white, except a little yellow on the lip, and borne in racemes. Then you may also select *Dendrobium nobile*, *Lycaste Skinneri* (a very useful species, the flowers large and pure white in the more expensive variety *alba*), *Masdevallia tovaensis* (pure-white, flowering at this season), *Mesospinidium sanguineum*, *Oncidium tigrinum* (the flowers richly fragrant like Violets, the lip yellow, sepals and petals barred with chocolate colour), and *Orchis foliosa*, a splendid Orchid for pot culture. The last mentioned is quite hardy, but does well in pots. It bears a bold spike of bloom. C. F.

TREES AND SHRUBS.

THE MISTLETOE.

WITH the approach of Christmas and the general use of this parasitic plant (see illustration), a few of my readers may like to have a note upon its propagation and culture. *Viscum album* is the botanical name of the Mistletoe, and it has been used upon festive occasions for centuries past. It is a native of Europe, and also grows wild in Great Britain. A great many ancient superstitions have been associated with the Mistletoe, and at one time it was supposed to possess considerable medicinal virtues. But I will get closer to my subject, and first of all state that this parasitic plant prefers the Apple as a host plant. It may be grown upon several others, and the following represents the order in which they are esteemed by this shrub: Poplars, with the exception of the Lombardy variety, *Crataegus*, *Limes*, *Maples*, and the *Mountain Ash*. I think its rareness upon the Oak, combined with the religious ceremonies already associated with that tree, had much to do with the Druidical worship accorded to it. In France, and also in the fruit districts of Herefordshire, the orchards are much infested with it, and a regular trade

Mistletoe on an Apple-tree branch.

is carried on each year. Some authorities state that no harm accrues from its presence, but as it derives the whole of its nourishment from the host plant, with the exception of what it may obtain atmospherically, I do not think this theory will hold good. However, it does no little harm that my readers need not fear to

grow a tuft or two of their own. The berries are not ripe at Christmas, and to be successful some of them should be saved upon a branch either stuck into damp soil or placed in water until the early part of March. A better plan still is to procure a few from a growing plant; but as the birds are very partial to them there is some little difficulty in this. The bark of a young shoot between two and three years old is best to place them on, and although they may be simply crushed upon it by the fingers, it is much better and safer to proceed as follows: Make a couple of cuts in the bark of this shape >. It is of importance that the top of these cuts face to the centre of the tree; why, I do not pretend to say. Lift the tongue of bark gently, and press the berry beneath; and the tongue will retain the seeds until they germinate. Perform the above operation upon the lower side of the branches. There are two reasons for this; first, it is more protected from birds and sun; also the water from a succession of wet days will not put a stop to germination. During early summer, when the seed has produced a couple of leaves, bright sun will often wither them up before sufficiently established upon the host plant. This is avoided to a great extent by placing them on the under part of the branch, and birds are kept away by a little muslin being fastened around the spot. There is no harm in trying several, because the majority of them will perhaps succumb during the summer; if not, any overabundance can be reduced by tearing them away. P. U.

FORCING SHRUBS, ETC.

AFTER the turn of the days it may be deemed safe to introduce into a moderate warmth a few plants each of the hardy shrubs which have been duly prepared for early forcing, by correspondingly early potting in the case of home-grown material, if not already established and previously forced, or by using imported plants for first early work. One of the most reliable of all shrubs for the earliest use is

LILAC CHARLES X.; it will force well in a fairly brisk heat, although I would not advise undue haste when it can be avoided. Another Lilac of which I am disposed to think we shall see a good deal more of is that called *Mme. Marie Legraye*; it is not apparently quite so dwarf as Charles X., but it flowers very freely whilst still of small size. Being a pure-white it is an excellent companion to the first-named. These I start early, on a bed of leaves with a gentle bottom heat under pot. Vines already breaking. The moisture thus obtained will assist an early break without the foliage getting too much in advance of the flowers. Large plants of Lilacs which are still in the open ground, but are intended for forcing, had better be lifted and stood in boxes or baskets in readiness with some soil pressed firmly around the roots, but unless compelled to do so I would not start these plants too soon. Next to the Lilacs, note should be taken of the

EARLY RHODODENDRONS; those which flower naturally whilst the weather is still cold are the best kinds to select for early flowering. Of these the various forms of *R. Nobleanum* in scarlet, rose, and light shades of colour can hardly be said to require forcing, flowering so exceedingly early in a natural manner. I have often wondered why more use has not been made of this valuable early Rhododendron. Then there are the varieties of *R. præcox* and also one called *Early Gen*; these being dwarf kinds do not occupy too much, whilst they flower profusely, being useful either for cutting or in the conservatory. Of the early deciduous Azaleas, the *mollis* section are by far the best; where these have prominent buds and a good number of them, they should be started with the Lilacs. For the earliest blooming, I prefer those plants of *A. mollis* which have been potted up for one or two years and have plenty of roots without any of the check consequent upon lifting and potting. Of

ROSES, only those which are thoroughly established should be started early, and these even should not have any undue amount of heat. In private gardens the Peach-house just about started will suit them to a nicety. A few plants of the *Gelder Rose* duly prepared can like-wise be started soon. Of plants which I consider it advisable for the present to defer

placing in heat are the Deutzias, *Prunus sinensis* flore-pleno, *Spiraea confusa*, *Andromeda floribunda*, and *Kalmia latifolia*. In a few weeks these will give much better results, taking them then in successional order as quoted. What is really needed when dealing with these early-blooming shrubs is plenty of moisture to induce them to start into growth kindly. Three or four syringings during the day, with another at night-fall or in the evening, will be none too much. Do not allow them to suffer in the slightest at the roots from want of water. Where it is possible to accommodate them all upon

A BED OF LEAVES with a gentle warmth, moisture also arising therefrom, they will do much better than if stood upon slugs or on a dry bottom. As to successional batches, it is only necessary to say that a few plants introduced at the time of each respective kind is infinitely better than the hegec number with longer intervals between each. Later stocks now in the open should be carefully looked after; if they are not protected yet at the roots by being plunged, no time should be lost in doing it. For this I prefer a bed of ashes, the plants being plunged 2 inches or 3 inches over the rims of the pots. This saves the pots from breakage, and is also better for the plants themselves. Further protection can be given if needed by a top-mulching of short litter; this will safeguard the removal of any should we have a severe frost.

WORK IN SHRUBBERIES.

Now that the shrubs, after the leaves of the deciduous plants and trees have fallen, are being cleaned up and put in order, there are also a few additional items worthy of notice. Of course, the cleaning up and making tidy can be done in a perfunctory manner and nothing further attempted, but by taking note as the work proceeds, it is often possible to improve the appearance by removal here and there. Where shrubs are overcrowded (and who has not seen them thus?) it is thus easy to remove a smaller one than is being overgrown by a larger. If this kind of work be left until a more favourable opportunity, that will not come for possibly another twelve months; so my advice is to do such removing at once. As the work proceeds it will not be a difficult matter to find room for these surplus plants; at least, I do not find it so. Deciduous shrubs should also be pruned where found necessary, but by all means avoid the clipping process as illustrated in a practical, but ugly manner oftentimes in our public gardens. I have a strong aversion myself to the shears. On the other hand, by the judicious use of the knife or pruning scissors in thinning and regulating the growth, a deal of good may be done; and if this work be always followed up, the shrubs will always be kept in order. Those remarks have also an equal bearing with overgreen shrubs. In doing the work, however, in any case the flowering proclivities of the plants must be duly considered. At this time also there is another item worthy of notice. It is that of layering such as the *Aucubas*, the common and Portugal Laurels, or anything else available around the margins. This can be done easily by buying a few pegs always at hand, doing the work so as not to make it unsightly. No further attention will be necessary, but in twelve months' time there will be a lot of useful little plants at hand, which without doubt can be put to a good use. If so be they are not wanted at once, they can be bedded out in rows, to remain thus until a place is found for them. In this way I have propagated numbers of those shrubs, which are now large plants serving a good purpose, where otherwise the ground must have remained bare. In some spots swelling *Hollies* and *Rhododendrons* come up spontaneously; so also do *Yews*. These can be placed in more favourable ground and left for a year or two. *Laurustinus* I have also from seed now of a flowering size, which, if left where they germinated, would probably have succumbed before now. Commoner things, as *Horse Chestnuts*, *Sycamores*, &c., it is no trouble to secure where found necessary. In no way or another it is thus possible to keep the shrub presentable without any undue expense.

USEFUL SHRUBS.

St. John's Wort (HYPERICUM)

This genus contains some handsome plants, for the most part shrubs and under-shrubs, but including a few herbaceous perennials and annuals. The *Rose of Sharon* (*H. calycium*) is probably the most familiar; but there are other shrubby species of much beauty. Some of the perennials are good border and rock-garden plants, and the best of these is *H. olympicum*, one of the largest-flowered kinds, though not more than

A St. John's Wort (*Hypericum oligoneurum*).

one foot high. It is known by its very glaucous foliage and erect single stems, with bright-yellow flowers, each about 2 inches across. It furnishes handsome specimens that flower early, and its value as a choice border plant can scarcely be overrated. It may be propagated easily by cuttings, which should be put in when the shoots are fully ripened, so that the young plants may become well-established before winter. *H. Elodes* is a pretty native plant suitable for the banks of pools and lakes. *H. nummularium* and *humifusum*, both dwarf trailers, are also desirable for the rock garden. Owing to their dwarf compact growth, several of the shrubby species are well suited for the rock garden. Of these, the best are *H. egyptiacum*, *barbaricum*, *empetrifolium*, *Coris*, *patulum*, *uralum*, and *oblongifolium*, the one here figured. The last three are larger than the others, but as they droop they have a good effect among the ledges of a large rock garden or on banks. *H. Hookerianum*, *triflorum*, *aureum*, and *orientale* are among the kinds having some beauty; but the species from warmer countries than ours are apt to disappear after hard winters.

5110.—Plants in Rhododendron beds.

—*Lilium auratum* and some of the hardier forms of *lanifidum* will sometimes do well in Rhododendron-beds. Seeing, however, that there is a doubt about these, you had better plant the double and single forms of the Tiger Lily (*Lilium tigrinum*). These are quite hardy, and not so particular as regards soil as many of the other forms. For Rhododendron-beds you want erect-growing plants, and those that flower after the Rhododendrons are over. If there is sufficient room you may choose *tilloides glanduloveis*, as these grow erect and flower late in the summer.—J. C. C.

—This is the best possible position for Lilies of all kinds, and many other flowering subjects, hardy Heaths, *Andromedas*, *Gaultherias*, *Mezazias*, North American *Cypripediums*, &c.—E. H.

—If you read the replies about Lilies in the last issue you will get much information about the best plants for Rhododendron-beds, and nothing is more useful than the Tiger Lily. *Lilium auratum* is a splendid bulbous flower for planting in a bed of Rhododendrons, and the

soil is very suitable, whilst the rising shoots in spring receive sufficient protection from frosts. If the plants are not large you may have some of the dwarfier Lilies; but you will find all the information you need in the notes referred to.—C. T.

The Laurustinus.—Having regard to the extreme paucity of hardy plants that bloom naturally in the winter, it is somewhat surprising that *Laurustinus* are not much more frequently grown. How much more pleasing in form and beautiful now would five bushes be on lawns than are so many of the dark, dingy, flowerless *Panuses* so common in small gardens. I have seen several fine bushes of the *Laurustinus* blooming most profusely about Stribiton, and in front of one garden was an old hedge kept in place by annual pruning, almost the entire top and front of which were full of bloom. It is really a wonder that small *Laurustinus* are not commonly grown in pots for greenhouse decoration during the winter, especially in comparatively cool houses where tender plants fail to flower.—D.

5113.—Sun dials.

—I am not acquainted with any book on the subject of sun-dials, and I do not see how any one is to get practical matter enough to make a book on the subject, seeing that with a suitable dial and a compass it is not a difficult matter to fix them. Once in my time I had to assist in setting a sun-dial. The fixing of the base of stone was a simple matter for a practical stone-mason to do, the only difficulty being to get a perfectly level surface for the under side of the dial to rest upon. It was not so easy, however, to set the dial accurately, for the work was done in the autumn, when bright sunshine did not occur every day, without which, and the assistance of a compass, it is impossible to fix them in a reliable manner. My instructions from a clever London optician were to have the dial fixed punctually at noon when the sun was shining bright, and when the compass indicated its correct southern position. This would be at twelve o'clock, but we had to wait two or three days for the sun to appear to show its position at that particular hour. The slightest movement of the dial after it is once placed in position would, of course, make it inaccurate as regards indicating the correct time. In the case to which I refer a thin layer of Portland cement was spread on the stone base to receive the dial. This work was left to the last moment, when the dial was put on and afterwards adjusted at the right moment of time to its proper position. It was then weighted for an hour or two to allow the cement to set before the work of cleaning off the stone was completed. If you apply to an optician you will have no difficulty in getting one. Messrs. Negretti and Zambra, of London, supplied the one to which I refer.—J. C. C.

5087.—Name of a Lily.

—I should certainly say that the Lily is *L. speciosum*, sometimes called *L. hucifolium*. The bulbs should be replanted every two years, removing the small bulbs, and if you have low shrubs, such as *Kalmias*, plant amongst them, as this Lily likes a peat soil, and the richly coloured flowers are a strong contrast to the deeply coloured foliage of the *Kalmia*. There are several forms; allium, sometimes called *Kreutzeri*, is pure white and very beautiful, whilst *Melpomene* is deep-crimson, with deeper coloured spots; *roseum*, *rose*; and *punctatum*, white, spotted pink.—G. T.

5090.—Treatment of *Darlingtonia californica*.—This is a marsh plant, and succeeds best in peat and sphagnum moss. I pot the plants or place them in pans, well drained, and mix with the peat and sphagnum peat should be good (strong peat) some coarse sand. Pot the plants firmly, but do not let the sphagnum to grow on the surface. The pots should be plunged to their rims in

CHRYSANTHEMUMS.

NEW VARIETIES OF CHRYSANTHEMUMS.

With a view of keeping the amateur cultivators well posted up in the matter of new kinds of approved forms, I purpose describing them as they appear. An early notice of desirable sorts enables the small grower to make space for the new comers by discarding an equal number of older varieties where the conveniences for but just a certain number exists. I know of no body of cultivators that are more keen after new sorts than the amateur, and where exhibiting is practised it is an advantage to be in possession of new and fine kinds as early as possible. I do not propose to employ the terms used in catalogues for the description of all the varieties, because in some instances I find it difficult in making them agree. I prefer to use my own terms in describing the flowers, and to make a practice of not accepting a recommendation of any particular variety, except in cases where there exists no room for doubt whatever. The following belong to the Japanese section:

MME. THERESE REY is at once the finest white-flowered variety in existence. Well-developed blooms measure 8 inches in diameter, and of corresponding depth; the colour is white, with a faint tinge of cream, the florets are of medium width, and semi-drooping in habit, the growth is all that is desirable.

DR. MRS. WARD.—This is an American raised variety, with broad florets, which are hirante, the colour golden-anber, edged with brick-red; is pleasing.

PREMIER BOREL.—A flat-petalled Japanese of brilliant colour, this variety is charming (rose-magenta, a very warm rose, the reverse pale gold, which is visible as the flower expands). A variety possessing much merit.

ERICA PRASS.—An incurved Japanese of a pleasing shade of colour (warm-peach). It is a full, solid bloom, of good quality.

LOUISE.—For the amateur especially this is a deserving variety, producing splendid blooms on plants but 2 feet 6 inches high; the colour is flesh-pink, the florets are broad and massive, incurving neatly.

MME. EDUARD REY.—This Japanese is influenced in its colour by the time that the buds are "taken." Those developed from early "crowns" are pale-lilac, while those later are a pleasing warm pink. The florets are broad and curve at the tip.

LE PRINCE DU BOIS.—The colour of this Japanese is rich-yellow, fading with age to a softer shade. The florets are narrow, twisted, and have a drooping tendency. A very promising English raised seedling.

KENTON YELLOW is one of the best of yellow-flowered Japanese varieties, having a rich appearance; it is most striking as varieties of that shade are none too numerous.

MISS MABEL SCOTT.—The florets of this Japanese are narrow, flat, and full; the blooms are not of large size, but of excellent quality; the colour is golden-primrose, with a touch of bronze at the base.

MRS. CHARLES COX is a bronzy sport from M. Bernard, possessing all the characteristics in form of this Japanese, which to the exhibitor is important.

PETER PALMER.—This Japanese was sent on last year, but not much exhibited. It is a white of the purest class; the long sword-like florets make a full, bold bloom.

THOS. HEWITT belongs to the incurved section of Japanese. The colour is white, with pink stripes and mottles over the surface of the florets. A very desirable kind to grow owing to its excellent keeping qualities.

INTERNATIONAL.—This is an extremely large-flowered Japanese variety; the florets are flat, broad, and semi-drooping; the colour is lilac, with purple stripes; a bold, substantial flower, and for exhibition most promising.

ROYAL WINDSOR.—This bids fair to be an excellent decorative variety, belonging to the Japanese section; the florets are flat, pinky-white, with cream centre, as the flowers develop this tint passing away with age.

E. MOLYNEUX.

three buds from round the centre one, unless perchance the centre bud is malformed or injured, when the strongest of the outer buds should be selected, and the others removed. Large flowers can be obtained on dwarf plants by cutting down the plants to within 3 inches or 4 inches of the soil about end of May, and taking the first bud that appears on the new shoots. Dwarf-growing varieties that do well on a crown bud are best for this purpose.—E. B., Winchester.

5134 & 5138.—Outdoor Chrysanthe-mums.—Two correspondents inquire about outdoor Chrysanthemums. I am pleased to see that great attention is being taken in this interesting and important class of garden flowers, and with a proper selection one may have them in bloom from midsummer until November. The less the plants are "coddled" so much more satisfactory will be the result, as the Chrysanthemum is quite hardy when grown in the open, and ordinary soil will suffice. I do not care greatly for the summer-flowering varieties, as we have then plenty of other showier things in the garden, and Chrysanthemums practically all the year round are a little too much. It is always a mistake to overdo a thing, as when the proper season for the flower comes round one has but much interest in it.

Firstly, as regards the soil; this must be rich and well prepared, and if you propose to grow the plants really well, make the soil ready at once, and leave it rough for the weather to pulverise, and so to dry, sweeten. Good Chrysanthemums may be got from vigorous suckers, which will make strong plants. Late spring is a good season for replanting, and each plant must be firmly staked. Disclodding, if not carried out to an extreme, is important, but only remove a surfeit of buds, as then the flowers remaining will be larger. The following varieties bloom in early autumn, and are all of good colour. This is of the utmost importance, washy, delicate tones being quite out of place in the garden where one wants a bold effect.

Alies Batcher, a sport from a well-known outdoor variety named Lyon, has reddish flowers, shaded with orange. It is Pompon, like all those mentioned, and the reason for preference for this class is that the flowers throw off the rains better. Golden Shah (is a splendid yellow), Lyon (rose-purple), Pierce's Seedling (bronzy-yellow, and a good sturdy variety). The following are Japanese kinds: Alex Dufour (rose-purple), Arthur Crepey (light yellow), Comtesse Foucher de Careil (bright-orange shade), Feuille Bengale (orange, touched with crimson), Mme. Desgrange (a really indisputable kind), La Vierge (pure white, a lovely variety of bushy habit, and smothered with pure-white flowers), Mrs. J. R. Pitcher (bluish-lilac), Mons. E. Pynaert Van Geert (yellow, suffused with red), Rio des Precois (deep-crimson), Souvenir de M. Menier (crimson-red), and amongst the November kinds the purplish-rose Jules Lagravere, the bright-yellow Jardin des Plantes, and the old Emperor of China, also called Cottage Pink, a very free and graceful variety. If you plant plenty of these the garden will not want for colour at this dull season of the year.—F. P.

5138.—Chrysanthemum in the open ground.—When a proper selection of varieties is obtained a grand display can be had in the open, provided, of course, the plants are well attended to during the summer in the matter of cultivation. It is useless, however, to expect those sorts that usually are flowered under glass, such as the Incurved section, and the largest of the Japanese to give flowers any way near what the same varieties would under more favourable conditions. A proper selection of sorts that are best adapted to this form of culture should be chosen, the cuttings inserted early in January in a cool-house or frame, growing the plants on sturdily, and planting them out in the spring in well-prepared soil. If the weather is hot and dry during the summer a mulching of half-decayed manure laid on the surface for at least one foot around the stools or roots will assist the growth by maintaining the soil in a moist state. If some old roots could be obtained divide them into pieces, each having four or six shoots springing from the top. The month of March is a good time to make a new plantation from old roots. The following will be found a good selection:

Mme. C. Desgrange (white), Mrs. Hawkins (golden-yellow), G. Wernig (pale yellow), Mrs. Bunell (primrose), Mlle. Leon Lassali (creamy-white), M. Gustave Grunerwald (silvery-white), L'Ami Conderet (sulphur), Blushing Bride (rosy-blush), Precoite (golden-yellow), Mme. Picoel (light rosy-purple), Lady Selborne (white), Emperor of China (silvery-white), President (acorn-shaped), Solomon (rose-carmine), Alexander Dufour (rose-purple), Sœur Melanie (white), Ruby King (rich reflexed), California (yellow), La Vierge (white), Pierce's Seedling (bronze-yellow, golden-lilac), and White Cedar Nulli, Flora (yellow), L'Ami Couduchet (pale-yellow), Crimson Precoite, Mand Pitcher (bronze, free-flowering), Source d'Or (orange, gold-shading), and Leon Collin (bronze-yellow)—E. M.

5102.—Japanese Chrysanthemum.—The following are the names of a few kinds which have flowers of various shades of crimson and red, and this colour to me is the most pleasing of all, being so rich and decided: F. Tarks (reddish-maroon, a fine shade), J. Shrimpton (crimson-scarlet, very fine, one of the best of all Chrysanthemums, both for form and colour), Vice-President Calvat (crimson-red, the reverse of the petals gold colour), William Sewant (rich crimson, a deep, lustrous shade), G. C. Schwabe (carmine-rose, the florets long and twisted), Albion Lunden (velvety-crimson and carmine, a very fine flower), are shown well at several exhibitions this season. Cesaro Costa (deep-red, the florets broad and of great length), Edwin Molyneux (rich reddish-maroon), Jules Tussaint (bright reddish-carmine), M. Delux (red-crimson), M. H. Jucotot (crimson), M. Munsilluc (crimson-red), M. N. Davis (deeper shade of the same colour), Mr. C. Orchard (carmine-red), Stanstead Surprise (crimson, silvery reverse to the florets), and W. W. Coles (light-red, the florets long and broad).—C. T.

—The nearest approach to the colour (red) that I know is to be found in the following. They are more crimson, however, than red. As far as I know a pure-red variety has not yet been obtained: G. W. Childs (dark velvety-crimson), Elmer D. Smith (cardinal-red), Cesare Costa (dazzling-red), Mohawk (maroon-crimson), Triomphe du Nord (crimson-maroon), M. William Holmes (chestnut-red, faintly tipped gold), John Shrimpton (dark velvety-crimson).—E. MOLYNEUX.

5067.—Names of Chrysanthemums.—These varieties are quite distinct, Boule d'Or being a strong-growing, large-flowered Japanese variety, with twisted yellow florets, while Source d'Or is a smaller-flowered Japanese variety of a lovely bronze colour, one of the most decorative varieties in cultivation.—E. B., Winchester.

5119.—Pompon Chrysanthemum.—The varieties representing this section do not have incurved blooms. The true Pompon has short flat or fluted florets, which spread regularly or stand erect. Those which are round like a ball and of large size, smooth in their petals, belong to the Incurved or Chinese section. Those with loose incurving florets, but broader and longer, belong to the Japanese section, but are distinguished from the ordinary type, of which Avalanche is a specimen, and are termed Incurved Japanese.—E. M.

—One cannot judge of the names of the varieties from your vague description: but several of the Japanese, including Count de Goring, Mrs. Wheeler, and others are Incurved.—E. H.

5124.—Chrysanthemum for South Africa.—Plants for despatching to foreign countries need properly preparing, or else the chances of their reaching their destination alive would be small. If the cuttings are inserted in January and grown in cool quarters, thoroughly hardening them off, they will be ready for despatch by the early part of April. Shake the

5124.—Chrysanthemum for South Africa.—Plants for despatching to foreign countries need properly preparing, or else the chances of their reaching their destination alive would be small. If the cuttings are inserted in January and grown in cool quarters, thoroughly hardening them off, they will be ready for despatch by the early part of April. Shake the

5072.—Disbudding Chrysanthe-mums.—The usual practice is to remove the

bulk of the soil from the roots, pack them in damp Moss, and bind each one in a separate piece of oil silk, which prevents the evaporation of moisture. Place the plants firmly in a box, with the leaves exposed to the light, and hand them to the care of the captain of the ship with instructions to give them water occasionally. — E. M.

5108. — **Single Chrysanthemums.** — Insert the cuttings singly in pots 2½ inches in diameter in sandy soil the first week in January, placing the pots under halllights in a cool-house. Keep the frame close until roots are formed; except for an hour or so every morning, when the light should be removed to dissipate condensed moisture on the glass. When the plants are established in these pots remove them to a position near the glass, still in the cool-house. Here they will grow stonky by obtaining non-light and air. When 5 inches high pinch out the point of the shoot to induce the formation of side-shoots. When these have grown another 3 inches long take out the point of each again. Afterwards do not interfere with the progress of the shoots, but allow all to grow away uninterruptedly. Numerous side-shoots will push from the nodes of the main stems for fully 1 foot downwards. These will give a quantity of flowers, and enable the cultivator to cut sprays from 1 foot to 2 feet long, smothered with blossoms. Shift the plants to larger pots as the roots reach the sides until the strongest are in 9-inch pots and the remainder in 7-inch and 8-inch ones. A compost of three parts fibrous loam, one part of partly-decayed horse manure, with an addition of sharp silver-sand, according to the state of the loam, heavy or light. To every bushel of the compost add 1 lb. of Thomson's Vine-manure. Pot the plants firmly to induce them to make short-jointed and firm wood. An open position during the summer out-of-doors, where the plants will receive all available sun-light, is necessary. Strict attention to supplying the roots with water is a point to observe. If the plants suffer for want of it the foliage will decay prematurely, thus spoiling their appearance as decorative plants. When the pots in which the plants are to flower are full of roots a stimulant of some kind should be given, such as liquid-manure from the farm-tank, or that made by placing sheep, cow, or horse-manure in a bag in a tank of water, adding a small quantity of soot. In the absence of these things sprinkle a small quantity of any one of the many artificial manures advertised on the surface, watering it in with clear water. Do not, however, err on the side of too strong a dose or the roots are liable to be burnt, thus causing injury to the plants. A stout stake placed to each will be sufficient to support the branches, these being tied loosely to the stake. — E. M.

5071. — **Using a lawn-mower on tennis-courts.** — It is well to give the lawn a light cutting and rolling now or rather earlier, but during the winter very little attention is necessary, practically none at all. In the spring and early summer, however, there is much work to be done, rolling it occasionally, and mowing when necessary. It is not wise to let the grass get too long, as is sometimes done. At that time, before beginning to mow regularly, it is well to go over the grass very carefully, and remove Dandelions, Daisies, Hawkweed, and such like things, by spudding them out. This is the best and most effective method of dealing with them. — C. T.

— After October the lawn-mower should be cleaned and put away for the winter. At other seasons the lawn should be mown as often as is necessary. Generally speaking, once a week will do; but when the grass grows very fast in warm spring weather it may require to be cut twice a week. The roller should be used frequently, especially during spring. — E. H.

5121. — **Peat-Moss Litter.** — Peat-Moss litter after it has been used in the stable, is a good fertilizer for manure-poor land. Peat-Moss litter may be used for planting pots in in a 1901 frame before it is used in the stable, but not before. — E. H.

OUTDOOR PLANTS.

LILIES IN THE GARDEN.

THESE noble garden flowers have only within recent years been planted largely in the best possible way, and that is among shrubs. At one time it was considered suitable for pots alone; but under these conditions the finest growth and bloom were never obtained. Planted in the open, however, among Rhododendrons it is thoroughly at home. I was once much struck by the appearance of *L. elegans*, or *L. Thunbergianum*, as it is more often called, planted among dwarf, dark-leaved shrubs, *Kalmia*, &c. The contrast of leafage and flower was delightfully rich and telling—an unusual association of colour that is not seen in many gardens. We may make use of almost every Lily in this way, even *L. longiflorum*, which is often supposed to succeed in a pot in the greenhouse.

L. ELEGANS is a splendid early Lily, and now cheap, while there are many varieties differing widely in habit and colour of the flowers. The tallest should be planted among the shrubs, and in large spreading masses there are always openings through which can ascend the stately spikes of brilliantly-coloured flowers, reserving the dwarf kinds, those that grow only

full beauty of the variously coloured flowers is obtained. The bulbs are in the soil that suits them, and the growth is screened from heavy rains, cold winds, and late frosts. Those who have no large clumps of shrubs to plant it in should choose a sheltered situation for its position, not exposed to the full glare of the midday sun, and where the soil is rich and well drained. It will succeed in ordinary garden material, if this is well manured, but it likes best an admixture of peat and loam. The finest results with *Lilium auratum* have been obtained by planting it among Rhododendrons, and when once established amongst them there is no need to disturb the roots for several years. Varieties of *Lilium auratum* are many. There are so many beautiful gardens in England unadorned with Lilies planted in this way that it is important to make special allusion to it. Rhododendrons, or clumps of some kind, abound in every garden, but present a monotonous effect when their season of flowering is over, unless relieved by a rich display of bloom, as here advised. It relieves the scenery of tamenness and gives colour in the autumn. Some thought is now given to the autumn season of the year, and rich effects are gained by the free use of Michaelmas Daisies and Lilies. Writing of *Liliums* reminds me that the common

OUR READERS' ILLUSTRATIONS: *Lilium testaceum*. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. E. Baden Bengert, "The Grange," Knutsford, Cheshire.

from 1 foot to 18 inches in height, for the outside. Such varieties as the apricot-coloured *alutaceum atro-sanguineum* (deep-crimson, height 1½ feet), *Van Houttei*, *fulgens*, *citrinum*, or *Prince of Orange* (orange), and *cruciatum* (crimson), are all of dwarf growth, and adapted for edging peaty beds filled with shrubs. In growing the Lily in this form there is very little trouble occasioned. The soil that suits such shrubs as the Rhododendron also agrees with the Lily, and the growth protects the tender rising stems in early spring, when, except for this protection, they would suffer from frosts. A top-dressing of manure each year will keep both shrubs and Lilies in vigour, but it must not be dug in.

LILIUUM TESTACEUM (*Nankeen Lily*), figured above, is a distinct and fine Lily that does well in the soil that will suit Rhododendrons. The best Lily, however, for planting in this fashion is *L. auratum*, and I have seen it very fine at Kew Gardens in the autumn months, as there it has been made liberal use of for the enrichment of the scenery. The large masses of Rhododendrons on either side of the main walk are generally a picture of colour in autumn, the bold spikes of this Japanese Lily appearing in prominent places. The flowers large, numerous, and finely coloured, finer far than anything we can obtain in pots. It is under these conditions that

itself. **THE CANADIAN LILY** (*L. canadense*) is more common than formerly. Its orange and brown spotted flowers, borne on slender stems, are welcome in late summer, especially when appearing from amongst an undergrowth of shrubs. It succeeds well in London, and should be made use of in the parks and open spaces, which require colour in the declining days of summer. The Orange Lily, *L. davuricum*, *L. giganteum*, and *L. chalcedonicum* are good garden Lilies, but the last of the trio is best seen in northern counties or Yorkshire, where it is common in cottage gardens, and of finer growth than in more southern districts. Few Lilies thrive more freely than *L. Martagon*, the variety *dalmaticum* in particular. It is an exceedingly beautiful form, very telling when allowed to form a large clump, or establish itself in the wilder parts of the garden. Album is a suitable companion to it, and, like all the forms of the *Martagon* Lily, quite hardy, very free in growth and bloom, preferring shade, but not refusing to grow in the sunlight. I have referred above to *L. longiflorum*, and another reference to it may here be made to dispel the idle talk that one so frequently hears as to its thriving only in pots. I have seen bulbs planted among dwarf shrubs that were flowering remarkably well, and had been transferred two seasons previously from pots. The first year, of course, there were no great results, but the following season the plants made headway, and produced a delightful display of the most compact-shaped blooms,

quite as fine and as pure as, even more so, than those from under glass. This is an instance of the adaptability of the Lily for the open garden, and a good way to use what is always regarded as of value for pots alone. It is neither necessary nor desirable to give merely names, but there are a few groups that should be considered when planting Lilies in the open. These are the handsome Californian Panther Lilies—formerly *L. pardalinum* (Fig. 3)—stately, bold, and graceful kinds, with stems rising to a height of 8 feet, displayed to best advantage with shrubs as a ground work. It would be unfortunate to place such a type as this on a bare border; its characteristic growth suggests other conditions. The little Turk's-cap Lily (*L. pomponium*), (Fig. 1), must not be forgotten. It is lovely. The forms of *L. lanceifolium*, as it is more often called, are charming in the autumn, often grown in pots, but adapted for planting amongst shrubs. There are several varieties, the white, called Kratzer, and many spotted forms. The variety *rubrum* is illustrated on p. 595 (see Fig. 2). The autumn is the season for these, and, treated as advised for *L. auratum*, except that they should be amongst dwarf shrubs, they have a unique effect by reason of the bright rose shade in the flowers. They are not so vigorous nor so hardy as some, but may well be trusted to full exposure. Select a sheltered spot where winds will not damage the rising stems, and use for soil loam and peat. I have noticed that they remain longer in bloom than almost any Lily, commencing in September, and lasting several weeks in beauty. A gay succession is kept up by another splendid group, of which the Tiger Lily is a good type. This fine favourite, the delight of the cottager and all who love flowers, grows freely in ordinary loamy soils, likes a little shelter, and is adapted for planting among dark-leaved shrubs, as these afford the richest association of colour. All the varieties are good, and the season opens in early September, lasting on for many weeks. *Splendens* is one of the finest, while the double *fore-pleno* is also rich and striking with its showy flowers, which appear later than those of the other kinds. P.

GERMAN IRISES.

In all gardens, whether large or small, this type of Iris should be grown. They are splendid town flowers, and do not mind smoke and an impure atmosphere. The family is nearly allied to the fascinating Orchids. It comprises a wealth of distinct and beautiful forms, varying from the golden English Flag, that colours the stream-side and brooks with flowers in summer to the white *I. Robinsoniana*, late, stately, and a picture of late arching, glaucous leafage. But in the town garden the selection is limited, and should be confined to the "German" group, of which the Purple Flag may be taken as the type. The enthusiast in Irises, he or she who wishes to grow many kinds, may with reasonable prospect of success, take Irises in hand, and in a garden of my acquaintance in Islington they find a comfortable home, thriving with vigour, and giving each year a full return in the way of beautiful flowers. There is a wide selection of varieties, some with flowers of strange colours, artistic, and scarcely agreeable in their dusky hues, others bright and distinct. It is varieties of the most pronounced tints that should receive special attention, and the finest are the common type, distinguished by the rich colour of the faces and lighter standards. Here I may remark that the Iris has no petals in the common acceptance of the term. The erect central segments, as a rule narrow and bright in colour, are called standards, and the outer ring, those that are broader and richer in colour, are distinguished as "falls," a not inapt description, as they have generally a drooping tendency. Possessing probably all the common germanica or one of its improved forms as Purple King and atropurpurea, in which the flowers are larger and richer in colour, one may proceed further and enumerate a few other kinds of distinct shades. Madame Chereau is the great market Iris, the flowers always in demand by reason of their colour, white, cut into with further lines of lilac. Queen of the May is one of the most beautiful of Irises, the flowers soft rose in colour. Gazelle has the standards white, with

a lilac-blue fringe, the falls also white, but with a violet margin. Victorine, white and violet; Celeste, a glorious flower, bold, large, and of a delicious shade of blue; Dalmatica, lavender, the falls also of this colour, but with a suspicion of rose; Mandralisea, lavender-purple, rich and handsome; Rigolotte, yellow, except the falls, which have a primrose-coloured ground, reticulated with deep-brown; and Florentina, white, blooming just before the gay procession of germanica kinds begin. The finest is the noble *I. pallida*, which grows fully 4 feet in height, the flowers very large, and of a delicious mauve, but the delight of the artist. In growing all those that have been mentioned no great difficulties have to be encountered, which cannot unfortunately be said of the great Iris family in general. They are splendid border plants, relishing a light well-prepared soil and warm, sunny position. Many plants are killed with kindness, and the German Irises will suffer if disturbed much, as disturbance at the root will most certainly result in death. The amateur gardener of small experience has unfortunately a desire to continually upset the plants he wishes to grow to full perfection by removing them to another portion of the garden to give a fresh soil, or by digging about the roots as if a firm surface to the ground was necessary. It is a golden rule to leave plants in enjoyment of robust health alone. Irises need not be disturbed under five years, and then the operation becomes necessary by reason of the unaltered condition of the growth, and gradual absorption of the nutriment in the soil. In the flower garden, where there are opportunities of

Fig 1—Flower of *Lilium pomponium*. (See article "Lilies in the Garden.")

creating rich effects, the German Irises may be naturalised in half-wild spots, and the effect of the tall masses of flowers against the deep greenness of the leaves is delightful. Blue is a colour that agrees happily with the varied tones of green supplied by shrub and tree. P. P.

PLANTS FOR A SMALL GARDEN.

SEVERAL correspondents of late have inquired as to the names of a few good hardy things for a small border. I have just set down the names of plants that will thrive in all gardens, as a rule, whether suburban or otherwise, and hope this small selection will prove useful. They are all of vigorous growth, require ordinary soil, and flower over a long season, as will be seen by the accompanying remarks. A mistake commonly made is growing plants that are difficult to establish, or are not really hardy. It is idle to voppy gardens one sees in holiday times, as, in the southern counties of England especially, many beautiful shrubs and perennials attain to luxuriance, but these are not unfitted for suburban or more northern places. The selection is as follows, and all are hardy, requiring ordinary soil, whilst good plants can be purchased cheaply: *Erigeron speciosum* (mauve-purple, summer and autumn), *Rudbeckia speciosa* (yellow, black centre, same season), Pinks (particularly Mrs. Sinkins double white), Carnations, *Picoteas*, *Asters*, or *Michaelmas Daisies*, (in variety), *A. umellus* *bessarabicus*, *A. levis*, *A. Novi-Belgi*, and *A. Nova-Anglie* (in many varieties), *Perennial Sunflowers* (September and October), *Chrysanthemum maximum* (white), *Galega officinalis alba* (white), *Geranium inianum* (orange-scarlet, summer), *Roses* (par-

ticularly *Gloire de Dijon*), double and single-flowered *Pyrethrums*, *Ranunculus aconitifolius* fl. pl., (Fair Maids of France) (early summer), *White Day Lilies* (summer), *Double Soapwort* (*Saponaria officinalis* fl. pl., rose), *Campanula macrantha* and *C. glomerata* (*Jahurica* (rich-blue, summer), *German Irises*, *Achillea Ptarmica* fl. pl., (summer, double white flowers), *Adonis vernalis* (yellow, spring), *Hollyhocks*, *Alstroemeria aurantiaca* (orange, dry sunny spot, summer), *Alyssum saxatile* (yellow, spring), *Anemone japonica alba* (autumn, pure white), *Winter Cherry* (*Physalis Alkekengi*) (for its orange-scarlet fruits in winter), *Arabis alba* (white, spring), *Centaurea montana* (summer, flowers from white to red), *Delphiniums* (summer), *Doronicum plantaginifolium* *excelsum* (yellow), *Funkia ovata* (splendid leaves), *White Everlasting Pea* (summer), *Lilium croceum* (summer), *White Perennial Lavender* (summer), *Common Evening Primrose* (summer), *Ice-land Poppies* (summer and autumn), *Rudbeckia purpurea* (autumn, purple flowers), *Sedum spectabile* (rose), *Common Globe-flowers* (yellow, summer), *Honesty* (for its silvery seed-pods). For the shady border the orange-red *Hieracium aurantiacum* is of note, the *Evening Primrose*, *Solomon's Seal* (early summer), *Saxifrage*, not forgetting the *London Pride*, *Scilla campanulata* (blue, white, and shades of rose, spring), *Campanula lactiflora* (summer), *Perennial Sunflowers*, especially the branching kinds, and *Sedum spectabile*. The best climbers are *Clematis montana*, *C. Jackmani*, *fascicularis*, *multiflora* (winter-flowering, yellow), *Forsythia suspensa*, and *Crataegus lyracantha* (the Fiery Thorn, north or east aspect), amongst those that flower. I hope this selection will help those now planting small gardens. F. P.

SWEET PEAS.

FEW plants that are raised from seed have increased in demand like Sweet Peas, and the great advantage connected with growing them for market as cut flowers is, that the closer you keep the expanded blooms cut, the more successional ones there are produced. Nothing checks late flowering so much as leaving some of the first blooms to produce seed—in fact, I find it by far the best plan to grow a few especially for seeding, and see that all flowers on the rows devoted to cutting are kept closely gathered directly they are expanded. For a long spell of bloom the soil must be deeply cultivated and liberally manured. I usually sow the first crop in November in drills, keeping the rows about 5 feet apart; as soon as they begin to push through the soil some soot is dusted over them, and soil drawn up on each side of the rows, nearly covering them, and some brushy stakes are placed on each side of the row. The next sowing is made in February, in small pots, about a dozen seeds being placed in each pot. They are set on a shelf near the glass, in a cool-house or frame, when they soon germinate, and will be fit for planting out in the open ground in March. They must be gradually inured to the cold winds by having them in a frame from which the light can be drawn off all day, and when finally planted out should have stakes put on each side of the rows at once, and some evergreen branches to break the currents of cold air. In May they will commence to bloom, and should then have a good mulching of manure placed over the roots, and in dry weather plenty of water and liquid-manure, the quantity of bloom being in proportion to the supply of food available for the roots. New sorts are appearing every year, almost every colour being well represented, and the delicate tints of some kinds are very remarkable.

JAMES GIBSON, Gosport.

5130.—A north wall.—All the climbers that would suit otherwise are not evergreen, and you cannot do better than choose the Ivy, particularly *Evered's Gem* or the big-leaved *denata*, which has immense foliage, but the former is the neater and quicker growing of the two. Ivy clings well to the wall, and is finer in winter than summer, and insects do not eat the leaves.—C. T.

Ivy in some form is the most suitable plant for covering the north wall. The Irish Ivy grows very fast, but *Evered's Gem* makes a neater and better covering. I have never found any difficulty with horses and cattle eating Ivy, but sheep are very troublesome, and would soon strip off all the leaves.—C. T.

URBAN ACHAMPAIN

THE CLOVE CARNATION.

THE most familiar Carnation is the "Clove," and it is a charming town flower, flourishing year after year in the heart of London, and apparently enjoying a coating of sooty deposit on its glaucous leaves each autumn. The winter of 1890-91 was memorable for the density and frequency of the thick, yellow, sulphureous fogs that often make London a city to get out of in the autumn and winter. From November until the warm rains occurred, the leaves were

Fig. 2.—*Lilium speciosum* var. *viridum*. (See article "Lilies in the Garden," page 594.)

black with soot, but in spite of this covering and months of hardship from frost, the plants in the following July blossomed forth sweetly. One of the happiest houses for the Clove Carnation in London is in the Embankment-gardens at Charing-cross, where it is planted largely, and the bold clumps, spreading out into large masses, give a glorious display of flowers. There is also the White Clove, known by the name of *Gloire de Noney*, probably a sport from the crimson, and it is a good companion for the type, possessing the same vigorous constitution, and providing handfuls of flowers, rich in scent, and a mass of petals. In many large gardens there is a reserve border of Carnations of the self varieties to supply cut bloom, as the spikes of Carnations are of the greatest use for filling glasses and bowls in the house. Ordinary soil will suffice; and it is pleasant to see the plants in large clumps at intervals in the border, and also to find that the colours are self—that is, confined to one shade alone, as the deep telling crimson of the Old Clove. During recent years there has been a marked advance in the improvement and cultivation of the border Carnations. At one time it was considered as a florists' flower only—that is, grown for exhibition under glass, or in not under glass, at least brought under cover before the flowering season. But pot culture is not the only method to adopt, and each year the Carnation grows in importance as a strictly garden flower. Several new varieties of exquisite beauty have been added, and the list is steadily growing. A variety of distinguished merit should have a strong constitution, producing a wealth of foliage, or "grass," as it is technically called, and carry a spike of flowers of one decided colour or shades of one colour, large, sweetly scented, and not splitting the calyx or petal. The great fault of the older kinds and some of the newer acquisitions is the fatal characteristic of splitting the pod, thus letting free the masses of petals, which dangle about and present to view a bedraggled, useless bloom. I have seen borders almost filled with such varieties as Ruby Castle, a lovely pink, wonderfully free, and with flowers of neat shape, hold well through the slender calyx. With the rise of the Carnation as a plant for the garden has also come a better conception of its capabilities for resisting frost. It is quite hardy, as hardy as the Rose

or the Honeysuckle, but upon some soils it has an unfortunate disposition to die in winter. In good, well-drained ground it will thrive, and several large collections went through the recent protracted winters without suffering the least injury. One great point is not to coddle the plants by paucifying them in frames or houses. Let them take their stand in the open, exposed to wind, showers, sunshine, and frost, thus raising up a race of plants of a strong, hardy constitution. It is a great thing to plant out early—that is, some time in early September, to enable the layers to become thoroughly well established before winter, and this is a far better plan than keeping out the young plants in pots in frames, transferring them to the open ground in March. It is then that they are troubled with keen winds, which seem to dry up the moisture from the leaves, and prevent their full establishment in their new quarters. The result of this is that the flowering season is late and poor. In some of the London parks the prettiest beds are planted with Carnations, Clove and otherwise, one variety to a bed, and the surface of the soil carpeted with the spreading Tufted Pansies or the fragrant Musk.

K. P.

5139.—**A border of Gazanias.**—I am not surprised that you should feel interested in the behaviour of the plants in the border devoted to Gazanias, not so much from the fact that it is not unusual for them to do so in some places, as I have frequently seen them in flower in November after a sharp frost both in Devonshire and Somersetshire; but it is strange that the flowers should remain open longer during the day in the autumn than in the bright days of summer. I do not know if you have noticed this. I think, however, you must have done, or you would not have been so struck with their behaviour at this time of year. It probably wants another Darwin to tell us how it is that the flowers of the Gazania close earlier in the day in summer than they do in the autumn?—J. C. C.

— I do not see anything very unusual in these flowering on until the severe frost of a week or so ago; after, doubtless, the note was written, we have had no frosts of great severity. Gazanias produce much successive bloom when in a suitable position.—C. T.

5121.—**Dressing for a tennis-lawn.**—No, do not use the soot from a boiler flue, unless it is pure coal-soot and of a deep-black colour. The grey soot you mention contains a good deal of phosphorus, and is not a safe fertiliser. Either use good soot or wood-ashes. Scrapings from the roadside are also excellent as a dressing. If manure is used, avoid that made from rotten weels, as it will probably contain much seed, and it is astonishing how full of vitality weels are in this respect. A good dredging with rough lumps will do an immense amount of good after the dressing has been applied a couple of weeks.—P. U.

— Better throw this away. It is not soot at all, but chiefly (burnt) coke-dust, or fine ash, and nasty poisonous stuff. It would be much wiser and better to buy a little good soot.—R. G. H.

— The brown dust taken from a boiler flue is simply fine ashes carried up by the draught, and has little or no value as manure.—E. H.

5127.—**Monarda didyma and Tiarella.**—The first named is a hardy herbaceous plant, commonly called Bergamot. It grows to a height of 3 feet, and will thrive in any ordinary good garden soil. It is readily increased by division of the old stock in the spring. *Tiarella* is also, I believe, quite hardy.—J. U. C.

5057.—**Best Carnations.**—There are so many good Carnations that it would take up considerable space to enumerate even a fair portion of them. The following short list contains some of the best border varieties: *Germania* (yellow self), *Sybil* (rose-flake), *Mrs. R. Hude* (apricot), *Will Threlfall* (yellow), *General Baulanger* (scarlet), *Ketton Rose* (rose), *W. P. Milner* (white), *Merry Maiden* (rose-flake), *Pomgranate* (rose and scarlet), *Mrs. F. Watts* (white), *The Duke* (scarlet), *Blush Clove*, *syn. Saint Queen* (flush), *Snowman* (crimson bizarre), *Queen of Belders* (rose), *The Governor* (flush-pink), *Mrs. Henwood* (yellow and red), *Firefly* (rose and scarlet), *Purple Emperor*, *Old Clove*, *Rose Celestial* (rose-pink), *Alice Ayres* (white and carmine), *Countess of Paris* (white), *Rosetta* (pink), *Old Coia* (yellow, flaked rose), *Comte de Chambord* (creamy-white), *Safrano* (pink and red), *Miss Morris* (deep-pink), *Ruby Castle* (rose), *Mrs. Muir* (white), and *Mrs. Clifford* (white).—F. B., *Winchester*.

FERNS.

FERNS IN TOWN GARDENS.

FERNS are delightful in the town garden, for the simple reason that they will grow, and are not always showing signs of distress. I would rather have a healthy Fern than a sickly exotic, nursed into condition by much care and attention. And to the Londoner, or whatever large town the amateur gardener may live in, the Fern is a friend; it grows under conditions totally unfitted for plant life in general—that is, damp and partial shade. I once had a border of Ferns running by the side of a high wall in a suburban garden of the orthodox type, crowded, unwholesome, and ill-fitted to produce gay flowers. The soil was composed of the various muds left by the builder, and had become sour and hard through want of turning up and exposing to the sunshine and rains. Before planting the Ferns, much of this was removed, and some good loam and peat substituted as a foundation for the plants, clumps of moderate size were obtained, planted, and in the new staple quickly made headway, enjoying the shade and moisture, and giving joy to the owner by sending up stately fronds, creating a mass of refreshing greenery on a summer's day. One of the finest of all Ferns for this purpose is the *Lady Fern* (*Athyrium Filix-femina*), of which there are several interesting variations, and Fern fanciers, those who are charmed with the many departures from the normal form seen in the different genera, may make an interesting hobby of this class of plants alone in a suburban garden. Whilst making growth moisture should be given in abundance, not in drops, but in plenty, over the fronds as well as at the roots, to remove accumulations of dust

Fig. 3.—*Lilium parlatianum*. (See article "Lilies in the Garden," page 594.)

and the outpourings of chimeys. Of course in the winter, when the plants are at rest, it is not necessary to give artificial watering, as the ground is usually sufficiently moist to prevent decay. One of the finest varieties of the *Lady Fern* is *A. F. f. plumosum*, the fronds feathery, like a graceful plume, and of a fine green colour. Then there is *A. F. f. Victoria*, a noble variety, with large, handsome, and stately fronds. Even more suitable for the town garden is *Lastrea* or *Aspidium Filix-terrestris*, I may recommend the

Aspidiums in general as town plants, as they live and flourish in confined garages if given in the first place a good soil for a foundation, and plenty of water during the hot summer months, when all vegetation thirsts for moisture. There are many varieties, some curiously crested. If the love of the Shield and Male Ferns grows on acquaintance, it is very easy to put up a few to adorn the greenhouse, the window, or the apartment. The Hart's-tongue Ferns are a host in themselves. The common *Scelopendrium vulgare* is a familiar type; it clings to old rains, garlands many an old abbey with verdure, and does not disdain the humble quarters of a suburban plot. A large, broad clump is as rich and handsome as anything one can have in the Fern way, and lives in ordinary soil. A border might be filled with this *Scelopendrium* and its numerous forms, some finely crested, others differing from the type by reason of their stouter fronds. The Hart's-tongue like a shady position, and, therefore, may have a place in our border of hardy Ferns, but the important point to consider is the soil, which must be good, using that composed of loam and peat, with sharp silver sand added to make it thoroughly light and porous. As is the case of the other Ferns, syringe the fronds in the summer to remove dust, and they may also be grown in pots, the choicer varieties deserving this treatment. There are hundreds of varieties described, amongst the finest *S. latifolium*, *S. pinnatifidum*, *S. Kelwayi*, and *S. ramosa marginatum*.

V. C.

5103.—**Scale on Ferns.**—You should have given the names of the Ferns attacked, as in some cases it is not safe to apply any insecticide, as the majority of the Mitten-hairs, *Gleichenias*, and *Gymnogrammas*. This type of Fern is severely injured by strong insecticides, and the remedy is worse than the pest itself. In such cases go carefully over the stock, and remove those fronds badly infested, and picking off those on the younger fronds with a pointed stick. It is a tedious but necessary work, and this is the best time of the year for it. You will have to take the utmost care of the collection at all times, as scale is simply due to neglect. For the harder kinds of Ferns a very good insecticide is sulphide paraffin-oil, and have it very weak, about half the strength advised by the makers. It is a good plan to take off a frond or two and dip in the preparation to see if injury is inflicted, if not, then you may proceed and syringe. I do not care for paraffin, as a rule. It is a dangerous material in the hands of amateurs, but a splendid remedy in bad cases.—C. T.

— Unless the Ferns are valuable kinds, and the scale insects few in number, the best course is stamp them out by burning the plants, and this alone will prevent them coming again. If it is decided to make an attempt to destroy them without sacrificing the plants, mix up a strong solution of Gishurst Compound, and sponge the plants over, dislodging any scales which cling close with the finger-nail or a thin bit of wood. Several washings will be required to clear them off; in fact, when brown-scale gets in to a collection of Ferns it will take a good deal of time and patience to get rid of them. I should certainly throw out the worst plants, anyway. Three ounces of Gishurst to the gallon of water will be strong enough.—E. H.

5117.—**Treatment of Agapanthus.**—You have evidently seriously neglected the plants, as the *Agapanthus* is not difficult to grow. You should repot or rebut the plants, using a rich loamy soil, and give moderate drainage, as during the summer season plenty of water is necessary. Judging from your description, the plants are evidently thoroughly root-bound and starved, so to say, which is only remedied by giving fresh soil and making a new start.—C. T.

— These are very easily grown. They do best turned outside in the summer. Better see how the roots are; perhaps they are pot-bound. They are strong-rooting things. Certainly they have been neglected in some way, but without particulars it is impossible to say how or where.—H. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be prepared in the best manner and will appear in due course in GARDENING ILLUSTRATED.

HOUSE & WINDOW GARDENING.

CAMPANULAS FOR WINDOWS.

THESE succeed admirably in pots as window-plants. There are many beautiful varieties, of which the following are the most desirable for the purpose under notice: *C. Barrelieri*, a drooping kind with a profusion of star-like, bright-blue blossoms; its shoots hang down for about a foot in length, rendering it very suitable for suspended pots or baskets. *C. carpatia*, like and white, both very elegant, growing about 8 inches high, with numberless blossoms, extremely pretty for pots either in or outside of the windows; requires care in toxic gardens. *C. (Platyodon) grandiflora*, another drooping kind, but having far larger and more substantial flowers than *C. Barrelieri*, droops sometimes 2 feet, grand for hanging-pots or baskets indoors. *C. isophylla* and its white variety is a delightful trailing pot-plant for a window inside or out, and does well also if grafted on a stage in front of a window or in a greenhouse. The

Campanula rotundifolia.

pretty little *C. rotundifolia* (here figured) also makes an excellent window-plant in a cool room. *C. pyramidalis*, erect and branching, as its name implies—in fact, greatly resembling a Canterbury Bell, only the blooms are much more opened and flattened; this *Campanula* does well in pots for window-decoration. *Campanulas* delight in a light rich soil; equal parts of loam, peat, and leaf-mould, with plenty of sand added, suits them well. Do not put very firmly, and give plenty of water when in growth and in flower. Keep rather dry at the root during the winter, and divide and repot in the spring as soon as growth commences. The drooping kinds do best in slight shade. A 5-inch pot is large enough for each plant of the drooping kinds, and the pots should be suspended by means of wires, and the shoots allowed to droop over regularly all round. Use the same soil, but pot firmer for *C. carpatia*, and the tall pyramidal kinds, which grow 3 feet high sometimes, should be treated in the same way. It is, perhaps, best to divide and pot these in autumn, and when getting pot-bound in spring shift on into 6-inch and 7-inch pots. Use a more loamy soil and some old manure for them.

TABLE DECORATION FOR CHRISTMAS.

HAVING long been an advocate for simplicity and lightness in table-decoration, I would venture to offer a few remarks on the subject. There seems a natural tendency to run in excess in this matter. Many think that the more rare or beautiful plants, flowers, or leaves there can be piled on a table, the better the decoration. There can hardly be a greater mistake. As an illustration, I once saw a decoration in progress. Three light March glasses occupied the centre of the table; they were tastefully and sparingly filled with a light ham, and fringed with light Fern fronds, reclining on the damask cloth. Spraying out from these towards the finger-glasses, which were filled with choice flowers, were light, delicate sprigs of Ivy, so thin as to end in mere points of verdure. These were sparingly used, and the effect was charming—a perfect blending of lightness and simplicity. Strolling in an hour or two later, the decorators were still at work finishing—i.e., utterly spoiling their work. At the points where the graceful twigs of Ivy vanished towards the finger-glasses a stiff continuous double line of *Coleus* leaves had been hid on the cloth; and all among the Ivy, *Chrysanthemum* blooms in threes and in single flowers had been worked in as rosettes; similar rosettes were then stuck on at the corners. This tendency to overcrowding is generally rampant in flower shows. Again and again have I seen the most chaste decorations absolutely spoiled because decorators did not know when to stop. Sprays of the most exquisite grace, finishing touches, choice combinations that would have been the envy of artists, have been overlaid until completely hidden out of sight. Not only is

TOO MUCH MATERIAL USED, but the material is too much mixed. Nothing tends to produce monotony so effectively as the employment of all kinds of plants and flowers at once. It is hardly too much to say that each decoration should consist of one or a few homogeneous plants only. Not that only one flower may be used, though that often produces the most satisfactory results, but the flowers, foliage, and plants employed in any given decoration should develop into harmony through their congruity. Many flowers, however, are strong enough to stand alone, such, for example, as *Roses*, *Caneellas*, *Heaths*, *Lilacs*, *Valley Lilies*, *Lilies*, *Snowdrops*, *Primroses*, *Forget-me-nots*, *Spiraeas*, *Deutzias*, *Cyclamens*, *Ancunones*, *Lagerarias*, *Tacsonias*, *Staphanthis*, *Pastious-flowers*, *Gardenias*, *Otontoglossums*, *Dendro-linums*, and hosts of other plants and Orchids. With abundance of their own foliage and a few Ferns or *Falms* for extra greenery the most exquisite table decorations may be formed. The pure-white flowers may need a little support from others, such as *Squills* with *Snowdrops*, *Forget-me-nots* with *Spiraeas* or *Deutzias*, *Purple* or *Scarlet Bonnyarilias* with *Stephanotis*, &c. But with abundance of verdure it is astonishing how effective even white flowers may appear on a dinner table, especially as they may readily be fringed with bright *Coleus*, *Jesinea*, *Alternathera*, or other leaves. In harmony with their leaves what better table-decoration for Christmas than thickly-berried sprays of *Holly* and *Mistletoe*, supported with bunchlets of leaves and sprays of Ivy of different colours. For rosettes on the table Christmas *Roses* and *Caneellas* might alternate. The vases might be either filled with leaves and berries, to harmonize with the other decorations, or with bright flowers of promise of the coming beauties of the spring, such as *Valley Lilies*, *Spiraeas*, *Lilacs*, *Roses*, *Cyclamens*, or *Primroses*, not all mixed, but any one of them; or more choice still, *Calanthes*, *Phalenopsis*, *Otontoglossums*, or other elegant Orchids. Or, still more in harmony with the season, small plants of variegated *Holly*, *Golden Yew*, *Reticosporas*, *Laurustinus*, *Cupressus*, or other variegated or green foliage or flowering plants could be used instead of vases or rosettes of flowers. Such hardy plants are far more effective for Christmas decorations than the more tender Ferns, *Falms*, *Mirantias*,

Choruss, *Draecanas*, *Ardisias*, &c., so generally used for such purposes. And besides, the hardy plants in pots are within reach of all; young Spruces and Silver Firs are about as beautiful and effective in a young state as the most rare and costly trees or exotic plants. It

is the taste in the arrangement, not the cost nor the mass of material employed, that tells in Christmas and other decorations; and it may be added that the higher and purer the taste, the more sparing of material, and *vice versa*. A few touches of the pencil suffice the painter with genius, but the mere dabber's brush is ever in motion between the palette and the canvas. It is very much so with table decoration. A few bold touches please, while a multiplicity of intricate details land us in confusion and disappointment. And what is true of dinner tables and rooms is even more so of churches. The amount of "love's labour" absolutely lost on these at this festive season is appalling. Destined to be viewed chiefly from a distance, the greater part of the labour involved is seen imperfectly or not at all. Simple designs executed in durable material are by far the most suitable. Holly, Ivy, Mistletoe, Yew, Box, should form the staple, the warp of them all; while more perishable or scarce materials, such as flowers and berries, may be used more sparingly as the woof to slum up prominently in inscriptions or designs. For the furnishing of fonts, &c., there is no more useful plant than the Ethiopian Lily in flower, used with abundance of its fine leaves. It also has the merit of bearing the cold and draught of churches better than almost any other plant. Pyramidal or spiral plants in pots, as Yews, Hollies, Cupressus, Retinosporas, Laurustinus, Euonymus, Box, Bays, Myrtles, Acaecias, Gum-trees, &c., are also invaluable, as well as the more hardy Palms, Yuccas, Aloes, Ferns, &c. In warmer churches, Azaleas, Camellias, forced Rhododendrons, Lilacs, and any other greenhouse or stove plants may be used. Few plants are more effective than good specimens of Heath and Epacris; while Chinese Primroses, Bonvardias, Cyclamens, and forced Hyacinths, Tulips, Narcissus, Crocuses, furnish any amount of colour that may be needed. But to mix all these in one church arrangement would invite failure. Chrysanthemums are not named, as though several of the later Japanese and other varieties may still be in flower at Christmas, they seem to suggest a dead past rather than a joyous present or a hopeful future. This may be a mere fancy, and it must be admitted that Chrysanthemums last long and are showy in Christmas or other decorations. But a decoration of leaves and berries only is far preferable to one in which flowers already partially faded form any part. D.

PERSIAN CYCLAMENS FOR A WINDOW.

THE splendid effects which are now to be had from these plants are far superior to the smaller old forms, being finer both in foliage and bloom; and they are not difficult to manage in the sunny window of a room with a constant fire, unless gas be burned, which destroys them. Few room plants last so many weeks in blossom during the winter, throwing up their sweet-scented flowers continually for months if well supported. Plants which have not been too severely forced can now be procured covered with buds, and these will open well in a south window, the plant being copiously supplied with tepid water, but not allowed to stand in it, the saucer being emptied half an hour after watering. Cyclamens should never become very dry, even after flowering they must not be "dried off," a process which results too often in their destruction; but they do not like stagnant water, which rots their lower roots, nor can they endure a sharp draught. If the window be opened in the early morning in the room in which they stand, the buds are apt to get a chill and wither away; the plants are therefore best removed to a bedroom at night until the necessary sweeping process has been gone through and the window is again closed. Or they may be placed in a sheltered corner and covered with double newspaper, which saves them from dust as well as from chill at night during the winter months. Sponging their foliage with lukewarm water whenever dusty is very beneficial to them, and if green-fly or thrips should attack them, a little Sunlight soap will be found an excellent insecticide in the water. A mulch of fresh, green Moss placed round the tubers (which are usually considerably above the soil) will both add to the appearance of the plants, and keep them pleasantly moist, thus helping them much.

The pure-white Giant Cyclamen is very elegant, White Butterfly, with marbled foliage of green and white, being specially handsome. Vulcan, an immense flower of the richest crimson, makes an excellent contrast to the pure-white; while the pink-tipped varieties, and those with a crimson eye and white petals, are quite as beautiful in their way. After flowering Cyclamens should still be sheltered indoors until frosts are safely past, keeping them fairly moist, although they will not need so much water as when in bloom; they can be turned out of their pots into a half-shady border in June, where they will rest until the autumn, although they must not be allowed to become too dry during hot weather. They should never completely lose their foliage, and if given a little soot-water or other weak liquid-manure once a week they will become strong for the next season, and can be potted up in September, placing them then in a sunny window, as near as possible to the glass, to form their flower-buds. Good drainage, and a light, rich compost of loam, leaf-mould, sand, and sand, will suit them; and the tubers must be placed well above the soil, only half covered, leaving an inch of space empty at the top of the pot to give room for thorough watering. Treated in this way, a Cyclamen will do well for several years. J. L. R.

5051. — Dracenas in a room. — The amount of water needed by these plants in winter is not usually so much as in the summer; but it differs greatly according to the vigour of the plant, and the temperature at which the room is kept. The right time to water any plant may always be known by the state of the soil on the surface; this should be decidedly dry (not wet enough to soil the fingers) before water is given. Then, however, the plant must have a thorough supply, after which it will want no more until the surface soil is dry again. The water given to pot-plants should always be a trifle warmer than the atmosphere they live in, and rain-water is preferable to hard water for plants. The health of room-plants depends much upon their being kept very clean by sponging the leaves, or giving them a douche from a rose-pot or syringe when they need water, first placing them in a bath or tray. If the surface soil be sour or green, it should be removed to the depth of an inch or two, raising it carefully with a small stick without injuring the roots, and a little fresh sandy compost laid in its place. This often helps a plant greatly, especially if a teaspoonful of soot be added to the new compost. — L. R.

5082. — Making a window-box, &c. — These should be at least 10 inches deep, and 12 inches will be better for the plants, as it will allow for drainage, and also give an inch of room for watering at the top. Holes are not necessary in the case of wooden boxes, though they are needed when china or zinc is used. The box should be of the length and breadth of the window-sill, and have a small graduated piece of wood nailed on at each end and in the middle to allow air to pass under the box and to make it stand level, as window-sills usually slope downwards. No great ornamentation is needed, for the box should be covered with trailers. Neatly cut notches at the top, and two coats (outside only) of dark olive-green paint will be sufficient to make it neat. After placing a few bricks and ashes at the bottom the box should be filled with a good, rich, light compost of loam, leaf-mould, sand, and manure. This can be bought ready mixed under the title of "potting compost," by the hushel, at a good nurseryman's. Before using it a twentieth part of the whole is scum brushed from the lines of the house may be added with advantage. This is a strong chemical manure, and also has the effect of driving out all insects. Small plants of Mahonia (Berberis) Aquifolia in berry and hui, Laurustinus in bloom, and Aucuba japonica, with coral berries, look well in boxes for the winter; but these should have their pots sunk in the soil to protect them from frost, and can be taken out in early spring, when sturdy plants of Wallflower, with deep crimson or brown blossoms, and an edging of Forget-me-not can be substituted, with pink double Daisies, Anemone, and Primroses. These should keep bright until the end of May, when there are numberless half-hardy plants to put out for

the summer, notably, Tuberosus Begonias, Marguerites, Blue Lobelia, "Geraniums," Calceolarias, &c.; but other notes on the best selection for creepers, trailers, and upright plants will be given in time for that season. It is now rather late for putting in bulbs, but a selection of these can easily be made from the advertisement columns and put in at once either between the shrubs or without them, such as Hyacinths, Daffodils, Crocus, Tulips, &c.—R.

5060. — Window plants in winter in London. — It is by no means an easy task to keep plants in health during the dark foggy days which are too common in London in winter. Especially so where gas is burned; and in this case no flowering plant will bloom, although it may possibly survive it for some time if already in blossom. The best selection of plants under these circumstances is the following: *Ficus elastica* (the India-rubber-plant), with fine broad leaves, *Seaforthia elegans* (the Bungalow Palm), *Corypha australis* (the Cablage Palm), *Phoenix dactylifera* (Date Palm), *Chamaecyparis elata* and *C. humilis* (Fan Palms), all most handsome. *Dracena indivisa* (the Dragon-tree), and *D. cuneata*; *Lantana borbonica*, and *Aspidistra lurida variegata* (the Parlor Palm, so called, though not a real Palm); this last is a very hardy and useful room plant. All these depend much upon the care they obtain for their health in winter, and specimens now procurable should not come out of a forcing-house, or the change of atmosphere will probably kill them at once. They should not be watered indiscriminately at stated intervals, for they should never receive water when the surface-soil is damp enough to stain the finger placed upon it; while at the same time they should never become dust-dry. Tepid water, given only when necessary (and this can be ascertained only by daily attention to each plant separately), should be supplied in sufficient quantity to run through the pot, the saucer being emptied half an hour afterwards, for stagnant water will rot the lower roots. Never give a few teaspoonfuls daily; this too common plan is fatal to many plants, for it results in the starvation of the large roots below, while the fine surface roots are rotted. The foliage of these plants should be kept very clean by the use of a bit of soft old sponge and warm (but not hot) water. The India-rubber-plant leaves, and those of the *Aspidistra lurida* take on a fine gloss from the use of a little warm milk and water when dusty. During very cold weather it is well to place a newspaper at night over each plant to protect it from the biting winds which are apt to blow through the room, while it is brushed out in the morning; or the plants may be placed together on a side table, and covered with some light woollen material at night. If a warmed bath-room be available, and the plants can stand there at night, a little steam being added to the atmosphere by turning on the hot-water tap for a few minutes occasionally, this will be a most desirable place for plants at night, and by means of keeping such Ferns as *Pteris serrulata*, *Pteris cretica*, *P. tremula* in this moistened air from the time just before the gas is lit until the next day at noon, they may be made to do well, even in London, and are thus made available for the afternoon decoration of a drawing-room. Plants in bloom will not stand long, except in houses where electric light has superseded their great enemy—gas; for the deadly effects of this last light are such that every blossom of such things as *Primulas*, "Geraniums," &c., fall at once on being exposed to it. Hyacinths, *Racaris*, *Daffodils*, and a few other flowers may be tried; but all should be removed to a spare room, or a bedroom, where there is no gas burned, before four o'clock p.m. at this time of year. Cut flowers, with plenty of foliage plants as above, will be found to succeed best. — J. L. R.

5143. — Cytisus plants in a drawing-room. — The plants have either been kept too wet or too dry, and a dry atmosphere will also account for their behaviour. It is most provoking, I know, but the change is very radical, and the fact that the flower-stalk decayed points to a too wet condition of the soil. The only thing you can do is to keep them in the window or in the open, heated at as nearly as possible an even temperature, and take special care with the watering. — This is a great enemy to plants.

INDOOR PLANTS.

LAPAGERIAS.

The culture of Lapagerias is better understood than a few years ago, but, judging from what has come under my observation, the simple needs of these glorious climbers do not in all cases appear to be fully realised. A mistake frequently made is that of giving them too much artificial warmth. I have seen some few plants both in pots and planted out; those were kept through the winter in an average temperature of 55 degs., but not one of them looked thoroughly happy. Lapagerias are like Camellias, cool-house Orchids, and many other things; the rich healthy leaf tint natural to them soon disappears if a certain temperature is exceeded during the winter months. They are, indeed, so hardy that in all but exceedingly cold winters I am convinced they will come through as well without artificial heat as with it. I have a plant in a large pot which for some years has stood at the east-end of a lean-to house. As all know, some winters are marked by periods of severe frost, and during one of these the heating apparatus gave way, so that the soil in the pot was frozen as hard as a brick and remained thus for quite a week. Not a leaf was injured; even the young shoots that are generally pushed up from the crowns, and which were then quite succulent, sustained no damage. The plant is still in perfect health, and bears a quantity of well-developed blooms and also a number of unexpanded buds. When any plant sustains such hard freezing with undiminished vigour, it is worse than useless to give it much artificial warmth in the winter season unless except in the case of such things as have to be forced into bloom. I have heard of Lapagerias being successfully grown in the full sun, but my experience of them is that the foliage loses the rich green natural to it under the influence of bright sunshine, and that there is considerable danger of the

older leaves dropping prematurely. I do not know how long the leaves remain green under favourable conditions, but for several years at least, so that if they drop within a year or two after formation, it is a sign that the atmosphere has been too dry. The first Lapageria I had did not thrive well for several years. Every summer many of the leaves turned brown and dropped, and the young growths from the crown withered at their points. I was much puzzled to account for this, as every year the plant broke freely from the old wood, and the young growths pushed up strongly from the base. A canvas blind, however, appeared to afford the necessary amount of shade. At length it occurred to me that the injury was done in the early part of the morning. The east end of the house was not shaded, and the sun shone fully on the plant up to 10 o'clock, and in June and July the power of the sun is often great at that early period of the day. As soon as I shaded the end of the house the discoloration of the foliage ceased, and from that time the plant did remarkably well. Lapagerias are, of course, seen at their best when they have a free root run in suitable soil, and in the case of houses of tolerably large dimensions this is the most satisfactory way of growing them. The greatest care must be taken in the formation of the border, especially as regards ensuring perfect drainage. The fleshy roots so quickly suffer from stagnant moisture that unless there is a free outlet for water the health of the plant is certain at some time to suffer. For a bed of soil say 2 feet in depth there should be 6 inches of drainage. This is by no means excessive, and will allow of copious waterings in the growing season without danger of souring the soil. Good peat with a little leaf-mould, a sprinkling of fibrous loam, with a liberal addition of coarse silver sand, is, I consider, the best compost that can be employed. Some crushed charcoal may also be added as giving additional security against stagnation. There is, I think, no better time for planting than the present. The young growths that annually push up from the base are beginning to appear, and if these come into full growth they are liable to sustain a check in planting. In the case of plants that have become root-bound it is inadvisable that the compost be made very firm round the old ball, otherwise there is much danger of the old soil getting dry, and when this is the case there is some difficulty in getting

it thoroughly moistened again. For this reason I do not consider it advisable to employ large specimens, especially if they have not been potted for some time. The roots form a thick mat, through which water does not so easily penetrate. Neither is it advisable to use small plants, as there is some danger of the soil becoming close and sour before the roots have taken possession of it. Although there is no comparison in the growth of plants that can enjoy

A FREE ROOT-RUN in good soil, and those that are confined in pots, a very fair amount of suc-

Double-flowered form of Lapageria.

cess can be had by pot culture. I have a plant in a 12-inch pot that has had no fresh soil for five years. This season it gave more blooms than in any previous year, and the foliage has the rich green hue that indicates good health. Naturally with plants in such a root-bound state high feeding is indispensable to keep the old leaves in good condition, and to encourage a certain amount of growth annually. During the growing season I top-dress about once a month with concentrated manure, and this, with abundance of moisture in hot weather, promotes a free growth. Frequent syringings are necessary, both as a means of creating atmospheric moisture and keeping off red-spider, which is sure to come when the air remains for days in an arid condition. Slugs are apt to be very destructive to the young growths that push from the base. It is a good plan to lay some Cabbage leaves about round the plants through the winter and examine them late in the evening, or better still, small heaps of bran. On mild evenings the slugs will come out to feed, and most of them will be caught by the time growth is being actively made. Lapagerias sometimes produce double flowers like the one here figured.

C.

5130.—**A garden-pit.**—The pit may be heated quite easily by means of either a flue or a hot-water apparatus. The former will come rather less expensive in the first place, and is somewhat safer in the long cold winter nights than a small boiler, but, on the other hand, it will consume rather more fuel. Make the first 5 feet or 6 feet—say across one end—of brick-work, and the rest may consist of 6-inch (rain (socket) pipes, jointed with cement. The flue should slope gently upwards all the way, and the chimney be 9 feet or 11 feet in height. If hot water is preferred, a single row of 2-inch piping all round the pit will suffice. Place the flow pipe along the front, and have a small "Star" or a plain coil boiler, set in the brick-work; either would do equally well.—B. C. R.

5111.—**Cyphomandra betacea.**—This plant, which is known as the "Tree Tomato" (though quite distinct from Tomato de Lave, which also goes by the same name), does best in an intermediate-house or cold stove. Being a tropical growth, it would probably succumb to a cold town garden; but as it attains a large size, it would not be suitable subject for a small structure.—B. C. R.

5106.—**Oreoper for a greenhouse.**—You could not do better than get *Plumbago capensis*, which will succeed well planted out in the house in good loamy soil on a well-drained border. It is very free-growing, producing masses of flowers when in a warm greenhouse, and these are of a lovely shade of blue, borne in great profusion. You could also have the white variety, which is exactly the same as the other, only that the flowers are pure-white. The *Plumbagos* are not too luxuriant, like *Passifloras*.—C. T.

—*Clematis Indivisa lobata* is a very pretty white-flowered creeper. Ivy-leaved *Pelargonium Mme. Crouse* is good also. A Tea Rose, such as *Climbing Niphetos* or *Climbing Perle des Jardins*. *Plumbago capensis*, *Habrobrunnis elegans*, are all more or less suitable for a greenhouse.—R. H.

5112.—**Acalypha macrophylla.**—This is a stove plant of a semi-climbing habit that I remember as being valued for its large dark green leaves, with sometimes a vein of crimson in them. The correspondent who sends this inquiry is not likely to do any good with it in a winter temperature of 45 degs.; even if he could do so there are many more beautiful and interesting plants worthy of the room than this one.—J. C. C.

—Forty-five degs. is too low. Give it a temperature of 60 degs.—E. H.

5114.—**A forcing-house.**—For a house of this size you will need about six rows of 4-inch piping, equalling altogether, with connections, &c., nearly 200 feet run. If expense is not an object, a small plain saddle boiler, set in brick-work, will be found as good as, or in the end better than, anything else, but one of the upright independent cylindrical boilers, of the "Star" type, will come much less expensive, will require no setting, and work steadily and well, though it will not last so long as a saddle. It may be as well to add that a height of 9 feet is rather lofty for a forcing-house, unless, of course, you intend forcing Vines or other large or tall plants, and if you could make it 1 foot or 18 inches less you would find a considerable saving in fuel, as well as the plants do better, being nearer the glass.—B. C. R.

5123.—**Tuberous Begonias.**—Do not pot the tubers now, or they may decay; the end of January (if you have a warm-house or pit to start them in), or any time up to the middle of March will be time enough to do so. Keep them for the present in a pot or small box with a handful of half-moist Cocoa-nut-fibre below and over them; or if marked singly, separately in small pots, and in any case safe from frost or damp.—B. C. R.

5140.—**Treatment of a Lemon, &c.**—I should begin cleaning the plant at once; every week's delay will only make it worse. Scrape off as much of the scale as you can, then brush the whole well with a strong solution of Gishurst Compound, and just touch the mealy bug with benzoline or paraffin; but if you use too much of the latter you will kill the wood. Cut it back, not too hard, in March, and then keep it warm and close, syringing frequently overhead, but giving water only sparingly at the root until well in growth again.—B. C. R.

5118.—**Begonia seed.**—It is quite possible to sow the seed and raise plants in a cold frame, but if this is done you must wait till quite the end of May, and then the plants will not flower till the following season. In order to get good blooming plants the same season the seed must be sown in January or February, in a steady moist heat of at least 60 degs. to 70 degs., and the seedlings be pricked off and grown on as fast as possible, hardening them off in May and planting them out in June.—B. C. R.

—Sow this in February in a temperature of 70 degs. Do not cover the seed with soil, but place a sheet of glass over the pan or pot, and keep it dark until germinated. Then stand on a shelf and prick off into leaf-soil and peat as soon as they can be handled. Keep them growing freely, and pot on to a rich, loamy compost. In June they may be kept more exposed to air, and eventually planted out in July.—P. U.

—To bloom out-of-doors next summer the seeds should be sown in the hot-bed in February, and be pricked off when large enough to handle, so as to have nice little plants in single pots, or pricked out in boxes ready to turn out next June. To do this they must be grown on in artificial heat till the middle of May, and then placed in a cold frame to harden previous to planting out in the beds.—E. H.

5109.—**Bulbs in pots.**—"Nemesis" will get but little success with most of the bulbs he mentions if grown the second year. Fresh soil will not for years it shaken out and repotted in fresh soil after they have had a rest; but the others are not worth the trouble of keeping in pots after the first year.—B. C. R.

THE CAMELLIA AND ITS CULTURE.

SOIL.—Many years ago Mr. W. Paul gave an interesting lecture on the Camellia at South Kensington, and some discussion took place as to the best soil and other treatment necessary for it. The compost used at the Waltham Cross Nurseries, where very successful results were obtained, was one of good turfy peat and yellow loam. The late Mr. Pearson, of Chilwell, considered that loam without any peat was better for the Camellia than any mixture, and he preferred it cut from an old pasture and used at once. Since that time I have tried many experiments with the Camellia, and amongst them the system of cutting turf from an old pasture where the soil was a light sandy loam. In this the plants did well for some time, but afterwards the growth was not satisfactory, and the foliage had not the dark glossy green hue so much desired. There is also a black spongy peat obtained from undrained boggy soil which is even more unsuitable than some loams. Sandy, turfy peat, on which Heaths grow freely, two parts, and about one part of good turfy loam, which grows Brackens and in which the Rhododendron will thrive, are the best. Add to this some crushed bones and rotten stable-manure. This compost is of a lasting character, and in it roots are formed freely, and do not perish if the plants are judiciously watered. The young roots of the Camellia are white, brittle, and easily injured. In repotting the plants, if these are in good condition, they ought not to be disturbed; it is not enough merely to remove any loose soil from the surface with a pointed stick; the broken potsherds should also be carefully removed from the base of the ball. Select pots 2 inches or 3 inches wider than those in which the plants were growing previously, and let them be clean and well drained, and press the compost in moderately firm. It is well not to give any water for a day or two after repotting.

CAMELLIA-HOUSES.—The form and style of house in which Camellias are grown has also something to do with their success. The modern system, with a large extent of glass surface exposed to the sun, large squares, and light bars in the roof is not the best. Such houses look well from an architectural point of view, but for the purposes of Camellia and Orchid-culture the closely-placed bars and small panes of glass are better than very large squares. One of our best practical gardeners near London once told me that it was his belief that the modern system of hot-house building had killed nearly all the fine old Camellias in the neighbourhood of London. In the old style of house so much shading was not required, the lightest material being the best, and its use was required during the hottest part of the day only. It is also believed by many that the small panes caused a purer atmosphere in the house, by promoting a healthy circulation of air where the panes joined. We have some evidence that this is of considerable importance in maintaining the health of the plants. To do the Camellia well a house with a west aspect suits it best. It should either be a lean-to or half-span. If a whole house can be given up to their culture it is comparatively easy to grow them well. They require an airy greenhouse temperature all the year round, except when they are making growth during the early summer months, when a close, moist, rather warm atmosphere suits them best. If Camellias have to be grown in a greenhouse with other plants they ought to be removed to another house while making their growth. When the buds are formed it is then a question what is to be done with the plants. If there is room under glass I would not think of placing any plants out-of-doors, but sometimes there is no alternative; then it is as well that they be partially shaded from the midday and afternoon sun, and also from heavy rains. The best place for them is a shady part of the greenhouse or conservatory, and they do well as greenhouse-plants (see illustration).

IN FORCING THE CAMELLIA in order to obtain early flowers, put the plants into the forcing-house early in the year, and let them remain until the buds have swelled considerably. I could often have cut plenty of flowers a month before Christmas, and had a succession until the end of March. The latest flowering plants are never taken out of the greenhouse. There they remain while making their wood, by

BUDS DROPPING. Camellia buds have a tendency to drop off if they are subjected to a change of culture when the buds are advanced. For instance, the plants remain out-of-doors in a partially-shaded place until the end of September, where the leaves are alternately drenched with dews and rains. At that time they are removed into the comparatively dry and warm atmosphere of a greenhouse or conservatory, with the result that many buds will drop unless the change is made gradually. This can be done by admitting rather more air than usual and syringing the Camellias overhead once a day.

The size of plants purchased, if any, may be according to requirements, but it is essential that they be healthy and free from scale. Young plants get into bad health from various causes, the most common thing being inattention to watering, and allowing them to remain so long in their pots that they become pot-bound. When a Camellia gets into this state it is difficult indeed to bring it round into good health. The best plan is to repot after removing the dead roots and needless soil. This should be done before the plants start into growth; they should then be put into a house or pit in which there is a moderate heat, and be dewed overhead twice a day, taking care not to overwater at the roots until fresh ones are formed to draw up the water. They must be well shaded from the sun until they start into growth.

CAMELLIAS PLANTED OUT.—Although most persons must be content with Camellias in pots,

Camellia in flower on a wall.

after all this is not the best system of culture. They succeed best planted out in a prepared border of good soil. I have seen them do remarkably well planted in the inside border of a vinery, or rather a greenhouse and vinery combined. The Vines were planted outside and did not quite cover the glass roof, and the management was such that the Camellias did not interfere with the Vines nor the Vines with the Camellias. There was annually a good crop of Black Hamburg Grapes, and in the case of the three large Camellias, Lady Hume's Blush, first prize, and the Old Double White, each of them

produced hundreds of blossoms annually. The Vines were not forced, and the roots did not run into the space given up to the Camellias; and, moreover, they were thoroughly drenched with water—root and branch—during the growing season.

THE VARIETIES OF CAMELLIAS are very numerous now, but the double white and *umbriata* are the most grown. *Imbricata* is a good red variety when that colour is required, and the American varieties sent out by Mr. Hovey should be in every collection. J.

RULES FOR CORRESPONDENTS.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 27, Southampton-street, Covent-garden, London.* Letters on business should be sent to the PUBLISHERS. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5106.—**Lobelia for a basket.**—Which is the best Blue Lobelia for a hanging-basket?—L. P. L.

5107.—**Poinsettias.**—Should old Poinsettias be cut down now, and will they then throw out shoots?—NOVICA.

5108.—**Drooping Fuchsias.**—Will someone kindly tell me the best drooping Fuchsias for a greenhouse?—L. P. L.

5109.—**Dahlias for show.**—I should be pleased if someone would name twelve of the best show Dahlias?—DARIA.

5110.—**Chrysanthemums for bush culture.**—Will someone kindly give names of twelve best Chrysanthemums for bush culture?—SENEX.

5111.—**Treatment of Vallotas.**—Will someone kindly tell me the treatment of Vallotas? I have some in pots, but they have not flowered for years.—E. C. M.

5112.—**A scented Fern.**—Will someone kindly tell me the name of a Fern that smells like new hay, where it can be got, and if it will do well on a shady rockery in the garden?—WEST BURNEY.

5113.—**Cooking green vegetables.**—Will anybody kindly tell me how to cook green vegetables—Spinners and Cauliflowers, &c.—without making a horrible smell all over the house?—ASTORIAN.

5114.—**Peat-Moss litter for stiff land.**—Will someone kindly inform me if Peat-Moss litter is a good manure for stiff land, to dig in, and as a mulching? Also, if it will do for a hot-bed?—S. S.

5115.—**Gloxinias.**—Can these be grown in a window of a room that has a fire lit every day? If so, will someone tell me the treatment required, and also when to plant? I have no garden or greenhouse of any kind.—AMATEUR.

5116.—**Gladiolus "The Bride."**—Will someone please to tell me the proper time to plant Gladiolus "The Bride," as I see "J. Groom" (despot) mentions in page 555 that he plants this kind when he lifts other sorts. Will the frost hurt them?—F. S.

5117.—**Michaelmas Daisies.**—I shall be greatly obliged if someone will give me the names of six of the best Michaelmas Daisies, different colours, not more than 30 inches high, and where I can get them? Please name only the number required, as more causes confusion.—J. C.

5118.—**Potting Lilium auratum, &c.**—I should be glad to know whether the bulbs of Lilium auratum, cultivated in a cool greenhouse, should be often repotted, and at what time of the year? Any other notes as to treatment during period of rest, watering, &c., would be esteemed.—E. B.

5119.—**Good Chrysanthemum.**—I should like to know the names of about eighteen Chrysanthemums that flower best on the terminal buds, and those that do best on the crown buds? I have found out this year that Margot blooms best on the terminal buds, and Avalanche is best on the crown buds.—AMATEUR.

5120.—**A cool lean to vinery.**—I have a cool lean-to house 10 feet by 8 feet high. I want to grow a Vine against the back wall. Which kind would succeed best? The house is heated to keep out frost in winter, and I wish to use the front staging for plants, &c., as well. Will the two succeed?—HEAVY BLADES.

5121.—**Osmanthus.**—Some large bushes of Osmanthus ilicifolius variegatus, which have been in my garden for many years, are now (December), for the first time, covered with small white flowers, faintly sweet scented. Is this unusual, and will they bear berries, and, if so, of what colour?—CARMARTHENSHIRE.

5122.—**Greenhouse Amaryllis.**—Will anyone kindly tell me the proper treatment for some choice greenhouse Amaryllis, what heat and soil they require, and what should be done with them after flowering? Mine do not look vigorous, and I had hardly any flowers last year.—M. E. H.

Haliburton are worth noting for outdoors, whilst amongst the red-flowered varieties Jules Lagravier is considered good, also the old Triumphant de Nois. Every garden should be brightened with Jules Lagravier. It is the best of all outdoor Chrysanthemums for November, resisting rains, frosts, and fogs well. It is used largely all well in the public parks, and even in the metropolis puts on a brave aspect, when its companions in the greenhouse are in full beauty. More of a purplish tone are Progne and Prima of Wales, whilst of the golden-coloured kinds, Golden Baverley and Jardin des Plantes may be noted. To this small list I may add Cottage Pink, very bright rose-purple, the flowers reflexed, and throwing off well autumn rains.—AMATEUR.

GARDEN WORK.*

Conservatory.

Frequent rearrangement is very desirable now: there is not much in the way of flowers outside, and I want to make the most of things under glass. Roman Hyacinths, even where there is no forcing-house, should be plentiful now; Perseas, also, are generally good this year, and with some; half-dozen will make a nice mass in a 5-inch pot, but a dozen in a 6-inch pot, the plants supported with small sticks, will make a nice specimen; and for conservatory work even larger pots, if well furnished, will be desirable. Marchal Niel and other Roses planted out in the beds or borders may be pruned now, thinning out weakly shoots and shortening other shoots back to firm wood. Other Roses in pots intended to flower under glass should have winter pruning is required, if not already done. Remove the weakly shoots which are not strong enough to produce flowers, and shorten back the stronger growths as far as possible to dormant buds in the unopened wood. Rich top-dressings are always useful to Roses, both in pots and also when planted out. There will still be a few Chrysanthemums in bloom; but for most of the varieties the season is over, and the work of propagation is now in full progress. On the whole, the season has been a good one, and the number of new varieties that will be distributed next spring will be made next year still more interesting as there will be much to look forward to. The big flowers still hold the front rank, and all these who hope to make any mark in the exhibition-room must get these. All this helps trade and raises money to circulate, and therefore to a certain extent benefits somebody. Look sharply after thrips on Azaleas and destroy them before the flower-buds begin to open. The cheapest way of doing this in the case of smallish plants is to dip them in a bar mixture of soap and lime; the soap-water may be prepared by taking up a peck of fresh soap in a bush and slinking it in a large tin of water, say, 20 gallons; rub water is lost. Stir the solution daily with a stick for a week, and then clarify by dropping in a lump or two of fresh lime—two or three pounds will suffice; water will only carry a certain amount of lime—all in excess will be precipitated, and will carry with it all impurities contained in the soap, leaving the liquid of a pale sherry colour, but quite clear. A pint of this clear liquid in a gallon of water should be strong enough to dislodge thrips and most insects, except perhaps mealy-bugs. There are at the time of writing indications that a cooler change is likely to set in shortly, and boiler fires should always be kept clean and free from soot. There is much loss of heat through neglecting to keep the flues well swept out with a brush. If there is a leakage in any of the pipes, have it seen to at once, as, apart from the loss of water, it interferes with the circulation of the fluid in the pipes. More Poinsettias and Bonarrias which are past their best to another house where there are regular fires to ripen the growth before cutting down.

Forcing-house.

This department will be in full swing now, as, besides the forcing of flowers for the conservatory and for cutting, there are other things, such as Strawberries, French Beans, and Tomatoes, to be thought of. Young plants of the latter will soon be in a state for forcing warm houses, and Lily of the Valley, both of which may be placed in heat if it should be necessary to push them on. Azaleas with well-developed buds, both Indian and the deciduous species, may be helped on now. The old Azalea pontica forces well and is well adapted for cutting, being so very fragrant. If a pit containing a bed of warm leaves could be given up to cover the blossoms would be very superior in both size and colour. The ornamental house created by a bed of fermenting materials being planted in a forcing house is of great value in encouraging healthy growth. Lobelias here not been sown for summer bedding no time should be lost, as plants brought on by cool treatment are the strongest and best. Any plants required to produce cuttings should have a warm pit now. A soft young shoot will strike when a hard one would snap off or fall to root quickly enough. The night temperature now should not fall below 64 degs.; under ordinary circumstances no ventilation will be required for some time to come.

Ferns.

The days will soon begin to lengthen, and new rigour will be apparent in old plants throwing up new fronds. Old plants of Adiantum cristatum which have been used to supply fronds for cutting may be cut down and kept rather dry and cool for a time; as soon as there are signs of growth shake out, divide, and start in smaller pots according to sized root. Less water will be required after a fortnight; too much water when the roots are inactive will make the soil sour, and the roots will not take kindly to it. Good loam will form the main part of the Fern

compost. Some kinds, especially Adiantum Farleyense, will grow in pure loam, but it must be of the very best quality and not too light or sandy. Do not let the ever-green Ferns get too dry; this is a mistake often made at this season, especially when Ferns are grown in mixed collections of plants in the greenhouse. When Maiden-hairs and other Ferns are taken to the rooms they are more commonly overwatered and the roots injured. When this happens the best course is to gradually withhold water until some of the fronds have been repaired, and then repeat, reducing the ball as much as can be done without injury to the remaining root, placing them afterwards in smaller pots. A temperature of 50 degs. will suit not only the greenhouse Ferns now for a few weeks, but a good many of the store species will be safe also. Many people grow stove and greenhouse Ferns together, and it is undesirable just now to have a temperature that will, until the time comes for the general repotting, suit all.

Making Hot-beds.

Very much useful work can be done with a well-made hot-bed or two, especially in the raising of young plants, such as Tuberoses, Begonias, Cyclamens, &c., as well as for forcing vegetables, including Cucumbers and Melons. The best and most lasting beds are made with a mixture of tree-leaves and stable-manure; the proportion of leaves to manure may vary from one-half to one-fourth; the whole should be thoroughly bleached and thrown into conical-shaped heaps. If there are leaves enough to hold the strong heat of the manure, to check the heat may be made up with only one turning, watering any dry spots as the feet are being made up. Use sufficient pressure evenly over the bed to make the bed steady and lasting; the pressure by driving out the air acts as check upon rapid fermentation, and so keeps down the strong heat. When the beds are made altogether with stable-manure the fermenting process must be carried on longer to get the manure into a sweet condition before the bed is made up. At this season for raising and propagating purposes the bed should be 2 1/2 feet to 3 feet longer and wider than the frame, and not less than 4 feet to 4 1/2 feet high. As soon as the heat rises in the bed, if the construction has been right, the work of propagation, &c., may begin.

Pot Vinery.

The Vines should be tied up as soon as the eyes have fairly broken and all surplus shoots removed. Do not overwater, especially since the plants are plunged in a bed of leaves. Very little ventilation will be required just now. I want the plants to grow, and until the sun-shine there is will benefit even if it is enclosed in the house; besides, there is no insect-air-tight. Stop all young shoots two leaves from the bunch; sometimes only one leaf is left, but two are better.

Window Gardening.

If greenfly should appear on Pelargoniums or any other plants wipe them off with a small sponge moistened with soap-water. This ought to be done twice a week, and, but is quite feasible when applied to window and room plants, especially when taken in time. Holding plants in spare rooms should be kept dry. It is better to trust to warm coverings than have a fire in the room; fires often go out when most required, but warm coverings are reliable and not so likely. Hyacinths and other bulbs coming on in the dark should have light when roots are moving actively.

Outdoor Garden.

Weedy lawns may be cleaned now. When a lawn is very full of large, deep-rooted weeds the best plan is to put in the turf rather thinly. Dig or fork over the ground, and get out all the roots of weeds. Make the surface level and then lay a bit, then weed the turf and lay it down again. When the turf is out then the weeds come out easily, and digging over the ground extracts the roots in much less time than weeding can do. I have lately seen several lawns that were much infested with weeds that would be treated in this way. If there were only a few weeds it would be cheaper probably to dig them out. Weedy lawns may be mowed now; a mowing of farm-yard manure would be both cheap and effective. Dung, manure, soot, and most artificial manure are used where plants are required. Bone-manure is more lasting in its effect than most things. Wood-ashes mixed with earth forms a good top-dressing. In making lawn-tennis-grounds when altering levels some of the good surface-soil should be laid on the new surface to lay the turf on, and a layer of sifted ashes placed just under the turf will keep down ferns and give a dark-green colour to the Grass. Fuchsias in the borders should have a mound of ashes placed round the collar of the plants high enough and wide enough to keep the frost from killing the base of the stems. The so-called hardy Endivias (Escarots) and others often suffer a good deal in severe winters in some parts of the country, although on the south coast they are hardly enough to do without protection. The gates of wind have played havoc among newly-planted things where not properly secured. Mistle-Tea and other Roses; standard Teas should have a little bracken drawn through the heads.

Fruit Garden.

In a forcing establishment the gardener now has his hands full. Early Strawberries must now be looked after, cleaned, and the surface made so firm in the winter, and if extra care added if it should, and if there is any reason to fear red-spider or green-fly, dip the plants in a solution, 2 oz. to the gallon, of Sunlight-soap. I have tested this in various ways, and find it a very cheap and effective Insecticide. Early vinerias, Peach-houses, and early Fig-houses will now be ready or starting possibly in some instances. Peaches are now on the way, and the pot-Vine-house started several weeks back. There is less demand for early Brapes now than there was thirty years ago. This is owing to the introduction of the late-coming sorts—Lady Howers's, Alphonse, and Gros Colman. Gros Colman seems to be very well established, having made way for the more compact-headed Gros Colman. There is a large trade in pot-Vines both for planting and fruiting in pots. Those who raise the Vines at home will soon be thinking of the time in the eyes. When raising Vines for planting during the forcing season there is no better way than to dip the eyes thrust firmly into soda and covered with a little rich

compost. The vines may be 5 inches or 6 inches square, packed close together in boxes, and the boxes placed on a hot-bed or placed on the hot-water pipes. Top-dress borders and beds of bush fruits with good manure. These fruits rarely fail to produce a crop, and should have more support given them than they generally get. Last season was so hot and dry that a little extra help may be required now. When the manure has been spread over the surface the borders may be forked over and left for the winter.

Vegetable Garden.

To obtain early Lettuces they must be grown under glass. They will do planted in the borders of cold Tomato-houses, the ground being thoroughly prepared before planting, and the spaces for the rows of Tomatoes being left unoccupied. Lettuces do not take much out of the land; but it should be borne in mind that Lettuces, after they make some growth, at any rate, are liable to be injured by frost, and even in cold houses, if unprotected, they sometimes suffer. A glass room is not always a sufficient protection. Therefore, when the thermometer falls very low during the night, or when the frost is severe, I have saved them by spreading sheets of paper, such as old newspapers, over; this not only keeps off frost, but it shades them from the sunshine during the day, which often does as much harm as the frost at night. Where there are plenty of tree-hives collected, or hot-beds, probably a bed may be spared for forcing Lettuces, or the beds which have been used for Asparagus will come in very useful for Lettuces or to sow early Radishes or Horn Carrots, though but little progress is being made with such things yet. The time is close at hand when something must be done. The early Potatoes must be looked over, and if the sets are not already placed in boxes or trays to get the crown-eyes planted, the matter should be seen to at once. Vacant ground, if any, should be trenched, ridged, or dug up, with a rough surface exposed. Works of drainage may be done now wherever required, and Box and other edges made good. On frosty mornings when manure wherever it is required. Tomatoes may be prepared in the same situations, such as close to a south wall, or early Cauliflowers. When a spot is specially prepared for a crop, especially an early one that is shared quickly, it always plants nearer, and the early border is always cropped more thickly than other spots in the garden. If a trench in a warm spot is prepared for early Cauliflowers they will produce very good heads when only a foot apart and in a single row.

E. HOSBART.

Work in the Town Garden.

Plants of the pretty variegated-leaved Coleus, though rarely grown in the greenhouse during the winter, require as much light to keep them alive through the winter as most other plants and more than any other. If the light is not abundant, especially in late autumn, they will soon show signs of distress, and will shortly collapse, the proper range being about 60 degs. to 70 degs. This will keep them slowly growing, and as long as they do that they are all right. The best place for the plants is on a high shelf or stage within a couple of feet or so of the glass, and they should be rather sparingly watered. Young plants from cuttings struck in July or August, and kept in rather small pots and poor soil, usually stand the winter best, and they begin to grow again in the spring. They produce quantities of cuttings, which are very easily rooted in a moderate warmth. The coloured-leaved Alternantheras and Felices so much used in carpet bedding also require a genial temperature during the winter, and the best way to manage the former at any rate is to lift and pot some of the old plants in September. In March and April cuttings may be taken in considerable numbers, and these will soon root in a brisk hot-bed, and make nice plants by the middle of June. Grasses and Lemon-plants in both very nice subjects for the town greenhouse or window garden; their glossy evergreen foliage is at all times handsome, and being so smooth is easily cleaned at any time with a little warm water and a bit of sponge. The flowers, too, are both beautiful and fragrant. Both are easily raised from the plant; pipe of ripe fruit (the thin seeds are useless), and a good time to sow them is in March or April, when there is usually a hot-bed of some kind at work, and then the plants become nice and strong by the following winter. Of course, seedlings are a long time before commencing to bloom—10 or 12 years at the least; but the foliage is always nice, and, if grafted when three to four years old, they will produce both flowers and fruit almost directly. Pots of Snowdrops and Crocuses are expanding nicely now in cool greenhouse temperature—in fact, neither of them will bear much forcing any time, and should remain in a cool frame or pit until the flower-buds can be seen, when a very gentle warmth will cause them to expand more rapidly. Continue to insert cuttings of Chrysanthemums as they become ready, bearing in mind that the majority of the Japanese varieties ought to be got to work a month or so earlier than the Incurved kinds. In almost all cases the cuttings formed of smokers that spring directly from the soil will give much better results than shoots proceeding from the stem.

B. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from December 30th to January 6th.

Made up hot-beds for Asparagus and Potatoes; Radishes will be sown among the Potatoes to come off before the Potatoes will require all the soil. All the Shankle roots have been lifted for the winter's forcing, the Hebe kept off, and the crowns, with some 7 inches of skin attached, laid in a border, ready for forcing when required. They will be covered with litter if the frost sets in, so that they will be available any time. Mushroom-beds are made up as soon as can be found for fresh beds in the house. The warmth of a new bed is a great help to the temperature of the house; therefore, as soon as an old bed is found to be best cropping, it should be removed, the site filled with a new bed, and, if a fourth or fifth part of loam is mixed with the short manure, there is not much time wasted in fermentation. Equals the soil and manure are thrown into a heap in an open shed, and when the materials are warm and steam is arising from the heap, the whole mass is turned over again and the bed laid up. In a Mushroom-culture nearly everything depends upon having good spawn, and if a

* In odd or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with equally good results.

stock of spawn is purchased and kept in a cold, damp place it soon spoils. Keep the spawn dry and warm and it will not deteriorate in any reasonable time. Took up a lot of Veitch's Broccoli, of which a considerable number are still left, most of which are starting up, and laid them in a deep trench, with just the hearts above the soil; mats and litter will be in readiness to protect them should it be necessary, as one night's sharp frost will spoil the lot. Still looking after Chrysanthemum-cuttings. Some of my town friends have finished putting in their cuttings; they say the plants in dull town atmosphere require more time. There may be something in this; the ripening process may be slower than in the bright sunshine of the country. There are still a few Chrysanthemum-blossoms left for cutting, of course, and one's interest, if it were not for looking after young stock and making the necessary purchases of new varieties, would begin to flag. Seven and sixpence seems a long price to pay for a new Chrysanthemum, which may or may not be an advance on the varieties we possess already; but we must have these new varieties if we are to keep in the front rank. I am sometimes inclined to doubt if the front rank men, all things considered, have the best of it. All men, I suppose, act according to their lights, and the excitement of public competition is, in the estimation of some people, the only thing worth striving for. Moved more bulbs. Spiraeas, Adneas, Azaleas, &c., to forcing-house for early blooming. I think my Freesias were never better than they are this year, and good pots of Freesias are charming things both for the greenhouse and the rooms. They are just as easy to grow in the window of a long room as in a greenhouse for early blooming without forcing. They should be potted not later than September. They may stand outside at first till they begin to grow, and then be taken to the window or placed on the greenhouse shelf in the lightest position available. This is a good time to plant Cucumbers in forcing-houses. When a house cannot be given up to them they may be grown in boxes, if only a few fruits are required. Sowed Tomato-seeds of several varieties, including Old Red and Ham Green Favourite. These will be grown on near the glass in a warm-house, and every thing done to hasten their progress. Finished unmailing Peach-trees on walls. Moved Roses in pots into span-roofed pit containing a bed of leaves, in which the Roses will be plunged. The plants invariably flower well under this treatment.

Effect of wind on trees.—Trees which grow in exposed situations have their tops always leaning away in the opposite direction from the prevailing winds, and the casual observer concludes that the branches have bent by the constant pressure of the wind and retained their position. Now, although such trees have the appearance exactly of trees bending under a gale, still it is not pressure in that way which has given them their shape. The fact is, they have grown away from the blast and not been bent by it after they grew. Examination of the branches and twigs will show this. We hardly realise the repressive effects of cold wind upon tree growth, which it partially or altogether arrests, just according to its prevalence. Conifers show the effects of this more distinctly than other trees. Owing to the horizontal habit of growth of the branches, they point directly in the teeth of the gale from whatever direction it comes, and cannot, like the Oak, lean over and grow in the opposite direction; hence coniferous trees growing in exposed situations produce good long branches on their lee side, while on the windy side the branches retain their rigid horizontal position, but make comparatively little growth, which is simply suppressed. Example: I measured the branches of a Norcumb's Spruce growing in a position fully exposed to the north and south. One branch on the north side of the tree had fifteen annual nodes or growths and was 7 feet long, and its opposite, had the same number of nodes, being of the same age, but was nearly 2½ feet longer, or 9½ feet, and all the lateral branches were proportionally long and well furnished.—X.

Nurses for trees.—With good nursing almost any shrubs or trees may be made to grow anywhere. Without it there are hundreds of places where it is hopeless to attempt to grow rare coniferous or common trees, such as Oaks, for instance. Whatever does best in the neighbourhood—whether it be Larch, Spruce, Scotch Fir, Birch, or even Broom—that is the best plant to use for nursing and sheltering the trees or shrubs we wish to ultimately predominate. Plant choice trees in the position and at the distances we wish them to occupy, but plant the nurses everywhere. Let them fill all the intervening spaces, almost embracing

the permanent plants on all sides, without actually touching them. The function of these nurses is to help the other trees to grow, just as ours taught us to walk. But in ahercal matters the nurse is often allowed to grow over and smother the tree it was meant to help; and so there has been a rebound against the whole system of nursing, and we constantly see trees of rare form and surpassing beauty set down in the open teeth of the wind. Is it any wonder that, thus exposed, they refuse to grow, become stunted, or die? Good nursing is the secret of tree as of animal health, but when the tree or man is once vigorous enough to grow or walk alone, nurses must be dispensed with.—F.

TREES AND SHRUBS.

CHOICE SHRUBS.

DAISY BUSH (OLEARIA).

These are Australian and New Zealand shrubs, mostly evergreen, some of which are quite hardy without protection. *O. Haasti* is the most valuable, being the hardiest and most beautiful when in flower, and it blooms in early autumn when most other shrubs are flowerless. It is a dense compact bush, 2 feet to 4 feet high, with small round pale-green leaves, very thick, and not unlike those of the large-leaved Box. Its small white Daisy-like flowers are very abundant, and are borne in broad flat clusters, the whole bush generally being covered with bloom. It begins to flower early in August, and continues in bloom for a month or longer. It is of quick growth, flourishing everywhere in light well-drained soils, and it makes a beautiful low-shrub. A very effective group can be made by

Spray of a Daisy-bush (*Olearia (Eurythia) ramulosa*).

planting several specimens together and intermixing the scarlet *Chauliopsis Breuchleyensis*, which flowers at the same time. The other *Olearias* now in gardens, though not hardy enough for the open, make capital wall shrubs. *O. Ganniana* (called also *Eurythia Ganniana*) is an evergreen, bearing a profusion of white flowers in early autumn. Other good kinds are *O. ramulosa* (here figured), which bears an abundance of small white flowers, *O. Forsteri*, and *O. dentata*, excellent for adorning warm walls with white blossoms in autumn. In the southern counties and warm coast districts all the half-hardy *Olearias* may be planted out in the open, and only require a slight winter protection. G.

The Holly and Yew are two valuable trees. They will grow tolerably well in the shade and in almost any ordinarily good soil; but in a rather dry, strong loam both do best, the Holly particularly. Though a difficult subject to transplant, I never remember the Holly to have shown any signs of distress from drought if the roots had had time enough to get

held of the soil; but the Yew occasionally suffers owing to the roots spreading out close to the surface. Hence the benefit trees growing on lawns and other exposed places receive from top-dressings, which should be placed over the roots as far as they extend. Still, though there are trees that prefer a dry, and others a moist situation, as a rule all timber trees prefer a soil free from stagnant moisture; hence the necessity of drainage in plantations, which may be carried out by means of open drains to a considerable extent, if the drains be cut in parallel lines at regular distances apart and kept open by periodical cleaning. I have known extensive woods drained in this way, when doing it otherwise would have entailed much expense.—S.

SMALL CONIFERS FOR A COLD HOUSE.

In reply to several queries, this is a difficult subject to advise upon, as there are really few conifers of the size and habit desired by your correspondents that are available for such a purpose. The delicately beautiful conifers of the Larch tribe alluded to puzzles me, as there is really no conifer to which the description would apply. Most conifers whose normal height is from 2 feet to 4 feet are broad and bushy in outline, while at the end of an unheated structure it will be necessary to have quite lurly subjects. *Cupressus Lawsoniana erecta viridis* will in pots be some time before it gets too tall, but this is of a dense columnar habit of growth. The little narrow pyramidal-shaped *Retinospora laetoclada* with its greyish-green foliage is very pretty and will retain its freshness for a long time in pots; while the *Huon Pine (Dacrydium Franklino)*, with its slender partially pendulous branchlets, might, if the winters were not too severe, serve for such a purpose. If a slim habit of growth was not absolutely necessary, I should be inclined to name *Prumnopitys elegans*, a pretty little Yew-like bush that is fresh and cheerful at all seasons, and *Thujaopsis delavata*, a very chaste Japanese conifer. A smaller form of this—*latericis*—like one of the *Sclagimellas*, but of a low, rather spreading habit, is a very beautiful conifer for pot culture. Of plants other than conifers may be mentioned the Chilean *Azara microphylla*, whose regular front-like branchlets are clothed with small roundish leaves of a deep-green hue. The smallest evergreen *Cotoneasters*, such as *microphylla*, *thymifolia*, and *congesta*, which in winter are lit up by their little brightly-coloured berries, are very pretty; while some of the Japanese evergreen forms of *Euonymus* might be of service. The same may be said of that curious Privet (*Ligustrum coriaceum*), whose very thick leaves are of an intense deep-green hue. After all, perhaps the best results would be attained by using some of the choicer and more moderate growing *Ivies*, as secured to a slight trellis they form very pretty screen plants, while there is a considerable amount of variety among them and all are thoroughly hardy. Unless in especially favoured districts, the Norfolk Island Pine (*Araucaria excelsa*) would, I am afraid, be too tender to winter in a satisfactory manner in an unheated house. H.

The Weigela for suburban gardens.

—This is a delightful shrub, graceful in growth, free in flower, and quickly making a respectable bush. Their popular name of Bush Honey-suckle is in allusion to their bushy habit and somewhat Honey-suckle-like character of their masses of delicately-coloured flowers. There are many varieties—the parentage either *W. rosea* or *W. floribunda*—and in a good selection a charming variety of colours may be obtained, some dark crimson, others almost white. But for proximity to towns, kinds bearing richly-coloured blossoms should be chosen, these always appearing in a better light than the more delicately tinted kinds, that seem to sigh for the purer air of the country. *W. rosea* and *W. floribunda*, or any of the forms with flowers of decided colours, may be chosen. Their likes and dislikes are few, but all agree in preferring a light soil and moderately open position to promote a full growth; avoid the pernicious fancy for over-crowding, cramming three plants into a space that can only properly contain one. It is also well to allow a free play, that the *Weigela* displays its many attractions, and the best planting should consist in

BRADY & CO. PRINTERS, 15, N. BROADWAY, LONDON, E.C.

removing weakly branches or shoots. I know of bushes of Weigela upwards of 6 feet in height, flourishing in spots that one would consider fit only for rank weeds; but they yearly hold their festival of blossoms, which takes the form of dense clusters of tubular flowers, so thickly crowded on the graceful branches as to almost hide the leafage. Weigela is their common name, but I see that they are classed in some catalogues under the title of Dierrilla. —C. T.

WINTER JASMINE.

The Winter or Naked-flowered Jasmine (a sprig of which is here figured) is a very distinct and handsome species of a trailing habit of growth;

Sprig of the Winter flowering Jasmine (*Jasminum nudiflorum*). Flowers bright yellow.

the stems are from 10 feet to 12 feet long, slender, very numerous, and much divided into small twiggy branches. In the warmer parts of China (whence it was introduced here), and under glass in this country it is sub-evergreen, but in the open air it is invariably deciduous. The flowers are large, bright yellow, and borne in great profusion along the sides of the young shoots. In mild seasons this fine shrub begins to develop its showy blossoms as early as December, but the usual time is from the beginning until the end of January, the flowers continuing to expand for nearly a month. When in full bloom it is a beautiful object, and the blossoms are all the more appreciated for their appearance when there is, out-of-doors at least, an almost entire absence of floral beauty; it is also worth cultivating for the sake of its leaves alone. Its free-growing habit makes it peculiarly suitable for covering walls, and as it is very hardy it is equally valuable for planting on bowers or trellis screens. It is also spoken of as a good town plant, enduring London smoke very well. B.

5181. — **Osmanthus.** — This has been flowering with great freedom throughout the autumn and early winter in several gardens to my knowledge, and is probably a result of the great heat and drought of the past season. The flowers are sweetly scented, and their profusion came as a welcome surprise from a shrub that rarely charms us in this way, although much appreciated for the rich and persistent verdure of its leafage. I have never seen or heard of fruits upon *Osmanthus illicifolius* and its variegated varieties, but there is an American species named *americanus*, which makes a small tree, flowers, and bears purple fruits which contain a nut that is said to be edible. —A. H.

— In Devonshire this shrub may occasionally be seen in flower and bearing a dark-coloured berry; but I have never seen it bearing either outside of that county. — J. C. C.

5110. — **Plants in a Rhododendron-bed.** — I do not understand your query, but I will name a few other plants, &c., which will thrive in the same soil. All Lilies will do to perfection, and have a grand appearance above the deep-green of the Rhododendrons. If these are too tall, then plant the Lilies in front of them. The Ghent Azaleas, also *Azalea mollis* will give a good variety of colour. *Kalmia latifolia*, *Andromeda*, *Persea*, *Pernettya*, and almost all "American" plants will also thrive. —P. C.

ORCHIDS.

VANDA SUAVIS.

This plant when it flowers at this season is particularly charming, because of its beautiful perfume, and the long time which the individual flowers last in perfection. "Lancashire Lad" sends me a flower from a plant which he says he has in bloom, with two spikes having fourteen flowers in all, and he farther says another plant about the same size has also two spikes just ready to open, so that my friend can skip and dance with joy and pleasure at having two of these *Vanda suavis* with two spikes on each plant, neither of them exceeding 2 feet in

height. Now, I am glad to find that my friend has found that *Vandas* can be flowered well by even a "Lancashire Lad" when they are still small, not that becoming of a good size detracts from their beauty in the least. If you want to grow these plants well they must not have excessive heat. You will then preserve the lower leaves, and you must not fumigate them with Tobacco, as that has the effect of making them lose their leaves, and they then get leggy and lanky. Whilst I have frequently seen plants of these *Vandas* flowering about the size given by "Lancashire Lad," and have thought in years gone by that these were the tops cut down from tall, leggy, old plants, and that the bottoms were stood away to break and to form lush plants, but as I grew up and began to learn more about plants I knew better. Now, at the present moment, I have in my mind one collection of these Orchids which are finely grown and freely flowered, and these plants are kept in a temperature which fell to 55 degs. in the winter which, however, I do not agree with. As these *Vandas* grow through the winter months they require some little warmth to keep them moving, and as they also need some little warmth to keep them doing, they must be kept warmer than 55 degs. to induce this growth; but the plants that I allude to are kept dry now, or next to it, at the roots, so that the flowers that are so welcome are only produced sparingly, and therefore the collection is bare of bloom for about half the year. I myself look upon *Vandas* of the tricolor section as being amongst the most ornamental plants in the whole order, for even when not flowering they present a sight which cannot be rivalled by any other genus with their dark-green leaves, and for this alone I would advise the readers of GARDENING who have stove plants to get a few and grow them also. They make a little more work in the stove to keep them clean and to prevent the foliage plants from smothering them up; but the flowers will be produced at different seasons—that is, if several plants are kept—and as these blossoms will last for a month or six weeks, and, moreover, these *Vanda* flowers can be had for nearly all the season, with their delightful aromatic odour pervading the whole structure. The blooms of the *Vandas* to which the variety *V. suavis* belongs are exceedingly showy, being spreading and each nearly 3 inches across, the sepals and petals

being nearly equal; the lower ones are, however, a little the larger of the two, and when fully expanded the petals are twisted when they are quite open, and they show their peculiar china-white lack-ground to the front, which is without spots or stain of any kind, but in the front are a lot of streaks, spots, and blotches of a deep rosy-purple. The lip is of a deep rosy-purple, speckled with rose in front and deep-violet at the sides by the base, and, in addition, it is most agreeably perfumed. I think I have reason to speak in enthusiastic terms of these *Vandas*, and to recommend them to the attention of my readers. The heat is not great to retain, and they will not take much trouble to keep them in a nice growing condition. They require good drainage to carry away any and all superfluous moisture, and to be potted in good fresh and clean Spagnum. When growing the plants delight in a humid atmosphere, and so that it will be seen they can be kept dry in the winter; but I like to keep the temperature a little warmer, so that they may be kept growing and give some of their fragrant flowers during the winter months. MATT. BRAMBLE.

5128. — **Orchids for cool greenhouse.** — "H. J. H." asks for six; he cannot do better than try the following: *Oncoglossum Rossi majus* (in bloom now), *Cyclopogon cristata* (in spike), *Lycase Skinneri* (in bud), *Cymbidium Lowianum* (in spike), *Cypripedium insigne* (in bloom), *Dendrobium nobile*. These will do well if the thermometer does not fall below 40 degs. —MARCUS LOVELL.

Indian Azaleas for forcing. — The most promising-looking plants of the best kinds for early forcing may now be placed in warmth. They can thus be had in flower by the end of January or early in February without any undue haste. The florists I know have been cutting *Azalea* flowers for some little time past, but as far as this pertains to private gardens, there is no practical utility in it. In these latter a succession is more what is wanted, whilst in the former it is more a question of getting the best price for the blooms. I do not favour bottom-heat even of leaves, but have no objection to standing the plants over fermenting material, the moisture arising therefrom being decidedly beneficial in encouraging the buds to swell freely. Too much water at the roots must be guarded against, but the plants must not suffer from the opposite extreme. By plying the syringe freely, thrips, &c., will be kept down, whilst it will also save watering. When plants have been forced a few seasons they will quickly respond to a little warmth about now; in fact, at times they will flower almost without any additional warmth. I have noted this in the case of *Roi Leopold* and *Deutsche Perle*, particularly the latter. The old white "alba" and *Fielder's White* with *Deutsche Perle* are about the three best of their colour. Of the striped varieties, *Roi Leopold alba*, *punctata rosea*, and *vittata elegans* are all reliable, the two latter hardly wanting any forcing. In the reds, *Roi Leopold* is still one of the most reliable to force early of the large-flowered type; *calyciflora*, a bright salmon-red, larger than, but somewhat similar to *amezia*, is a free-growing and as free-flowering a variety as that old kind, which should also be included. Another fine old kind is *obtusata*, a variety that is, in spite of its age, not nearly enough grown. The foregoing are the earliest are about the best to choose, as expensive kinds are not desirable. —H.

Libonia floribunda. — This is a plant that all amateurs could grow with the greatest ease, and yet we very seldom see it in their collections. It only needs a cool greenhouse or frame during the latter part of autumn, and will then come into flower and last until long after the new year. It is good for the conservatory or room, and if carefully watered will keep slowly for several months. All through the summer they are much best out-of-doors, and as they are hungry plants an occasional dose of liquid manure, especially when the pots are full of roots and the bloom buds are setting, will amply repay the little extra trouble. A sudden change of temperature, or drought, will cause the leaves to drop off; but if these points be attended to there is no reason why all should not have a plant or two well furnished with bloom all through the winter months. It makes a good window plant. —P. C.

FRUIT.

PREPARING FOR GRAFTING.

Those who have healthy but unfruitful fruit-trees, such as Apples and Pears, should now make the necessary preparations, while the sap is dormant, by heading down the stocks—a little above where it is intended to graft them, and by cutting off and laying in a stock of scions, so that when the proper season for grafting arrives which is, as a rule, a busy time in gardens, all may be in readiness. Different modes of procedure are necessary with the various forms of the trees; but the following plan will, as a rule, be found the best. Standard trees that have attained considerable size, but which are not of a kind that find a ready sale, are headed down and regrafted in great numbers in Kentish fruit orchards, and they do not now head them down so low as was the case a few years back; but the branches are sawn off when they are subdivided, or about the size of a man's wrist, so that a goal-sized tree will take from 50 to 100 grafts, and then a good head of bearing wood is very quickly formed, so that in three years from regrafting a good crop of fruit may be gathered. Dwarf trees should be sawn off as low down as sufficient branches can be got of the right size, but it is highly desirable to get several grafts on a tree, so as to quickly form a head. Espaliers or Cordons must be cut back close to the junction with main stem, and one scion put on each shoot; whereas on all trees that form a head two or more scions may be put on each. The scions when cut off should be correctly labelled and buried quite half their length in moist soil, so as to keep them fresh and plump, for if dried and shrivelled they are quite useless for grafting.

J. G. H.

FRUIT-TREES AND DROUGHT.

ALTHOUGH the drought has been over for some time, it is well to keep in remembrance the fact that fruit-trees suffer more frequently from dryness at the root than many are aware of. We see the surface soil looking wet, and conclude that all is well with the roots; but possibly at the same time the roots of large fruit-trees, that penetrate to a considerable depth, are dust-dry, and the tree is suffering in consequence; for even in the most luminant period of the year the buds need nourishing from the root, and if they are in a dust-dry medium it follows as a matter of course that injury will ensue, yet in all probability the trees will put forth leaf and blossom, but if no fruit follows there are plenty of excuses, such as the spring frosts and cutting winds, whereas, if screened from both, the blossoms could not have set, for they were injured months before. Stiff soils that hold the moisture longest in times of drought take a long time to get wet after the rain does fall. I remember once grubbing up some trees in an old orchard in Kent in the winter-time, when the cultivated soil was so solidened that we could not work on it, yet the soil about the roots was dust-dry, and it looked as if no rain had reached the roots for years, and there is little doubt but that when the soil gets very hard and dry that the water runs off all the elevated portions into the hollows, without penetrating the soil enough to reach the roots. Loosening the surface with steel forks would be a great help to letting the moisture into the soil. Fruit-trees on walls frequently suffer by reason of the borders being made too sloping, so that the water runs right away; they should be level for at least four feet from the wall, and at the approach of winter they should be loosened on the surface and boards put on for traffic, if nailing or any other work is being done to the trees, for unless the roots get rather an overdose of moisture at this time of year, there is little chance of its being made good later in the season.

J. GROOM, Gosport.

GRUBBING UP WORTHLESS FRUIT-TREES.

How much valuable soil is lumbered by worthless trees—some that never, or very rarely, bring any fruit, or if they do it is cracked or blemished in some way, so that the tree never pays for the ground it occupies, much less the labour bestowed on it, and the question comes—What

is the best thing to do? Well, if the trees are young and vigorous you may cut them down and graft with some other good sort in spring; but if at all old, or with any kind of disease such as canker on the wood, the best thing to do with them is to grub them right up and make firewood of them. Root-pruning is very well for those that can afford to experiment on their trees; but when profit is the object I look on root-pruning as a very doubtful source of revenue. It is surprising how many trees may be taken out of even well-managed orchards or fruit-gardens without reducing the average crop, for I lack on any tree that produces fruit that are not saleable as quite as useless as the one that refuses to crop at all, and certainly it is more difficult to prescribe a remedy, and although my trees are all comparatively young I never miss a winter without taking out a goodly number that do not come up to the standard required. It is a fallacy to suppose you have to wait long for a return from young trees, for they commence bearing at once, if of the right sorts, and if they require any great inducement to do so it is the best remedy to start afresh.

J. G. H.

SOME GOOD COOKING APPLES.

THE first Apple fit for kitchen use is Lord Suffield, which is of the Keswick-Codlin type, but larger and better, as it is a splendid cooker, and goes to pulp quickly. Following on the heels of this comes Warner's King, which is also a big, weighty Apple, ovate in shape, and when ripe having a skin of a rich yellow colour. To succeed this none are equal to Blenheim Orange, as not only is it first-class for dessert, but it is the best of the cooking kinds; it is also a capital keeper. Wellington or Dumelow's Seedling (here figured) is an Apple in high favour for market purposes, but the acidity is a little too brisk for some, and yet, for all that, it is a very desirable variety, bearing large, pale

Fruiting-branch of Apple "Wellington" or "Dumelow's Seedling."

fruit, a little coloured next the sun, and very solid in texture, the season of ripening being from November to March. Mère de Ménago comes in about the same time, and is a remarkably handsome large sort, with red skin and darker streaks, the flesh being firm and briskly acid, but not so sharp as the one mentioned above. Alfriston is also a late keeper and a good bearer, the fruit being large and of a light orange shade, with flesh pleasantly mixed with sugar and acid. Beauty of Kent is a very desirable kind, and so is Bedford

shire Foundling, both being large and first-rate in quality. Many other names of cooking Apples might, of course, be easily given, but it is better to have several trees of one kind than to plant too many sorts, as the result of growing a great number of kinds is rarely, if ever, a satisfactory one.

D.

POTTING VINES AND PLANTING THE CANES.

THE potting of Vines is often done in much the same way as that of any other plant, but from close observation the reverse treatment is required, and though the canes may not be required to force, equal care is necessary to get hard, short-jointed wood. It may be asked, what is there in the potting to create a short-jointed growth, as this latter is chiefly caused by the after management, or during the growth of the canes; but I contend much of it is due to the way the plants start and are potted, and not so much to growth afterwards. Of course, if the Vines are plunged in strong heat or grown in a hot, moist atmosphere, the growth will be pithy, with long joints and soft or hollow canes, no matter how potted; but to get the best results, such a course as this will be avoided, and the treatment given will avoid extremes in heat either at the root or top. It will be found that few growers of pot Vines now depend upon canes struck one year and forced the next. I am well aware it has been done, but it rarely occurs; indeed, the circumstances must be most favourable to admit of its being done successfully, and when such good results are secured by striking the eyes one season, that is, as early in the year as possible, and growing on into 8-inch pots or larger, cutting back and repotting the next season, say, in January, so as to get the canes hard and well ripened, there is a greater certainty of success and less trouble than with Vines grown one season and fruited the next.

THE PURCHASER OF POT-VINES examines his canes when bought from the best establishments, he will find this cutting-back system the one carried out, and therefore the most successful. Unfortunately, all do not practise the same system of culture, as at times one sees very fine canes; but if closely examined a gross growth does not mean a heavy crop. I would prefer a smaller cane, short-jointed and well ripened, to a large one full of pith, and when started producing a lot of long shoots with few bunches. Of course, if a large, well-ripened cane can be had, it is best and gives the greatest weight of fruit. The purchaser should secure well-ripened canes as described if hard forcing is resorted to. I have included planting canes in this note, as it is equally important to get these in the best condition for the work as when fruited in pots. Of late years I have noticed larger canes are sometimes used, so that equal preparation is necessary, as Vines planted with the joints far apart and full of pith rarely swell at the base, the bottom of the cane is contracted and therefore unsightly, and in time fails to produce fruit at the lower part of the house, the reverse being the case with the Vine in full vigour, the whole length of stem then bristling with shoots all up from the ground. I would add I do not like the system often practised of rubbing off the eyes of Vines in a young state when, say, several feet of stem is required; I think it prevents the roots growing or swelling at the base, and would prefer to stop after a few inches of growth have been made. Of course, in some cases it may not be convenient, but wherever possible I think it advantageous. This note refers to Vines grown on the two-years' system—that is, Vines struck one season and potted on into 8-inch pots and cut back the next. With Vines grown in one year it is not applicable, but, as I have previously stated, I consider the two-year plan the best. When

REPOTTING OR SHIFTING the Vines into the fruiting pots after being at rest, I advise a thorough shaking out or removal of soil and repotting into fresh compost. By so doing, a much better growth, with short-jointed wood and as hard as possible, is obtained. There is a great difference in Vines potted as advised. Two years ago I tested it, and got much better results from the shaking-out system, and when carefully done and the roots spread out as the potting proceeds there is no danger of injury to the Vines. Indeed, the roots seem

to revel in the new compost, and the cultivator need not fear the consequences if the work is well done. I am well aware such potting or shaking out requires more time and a certain amount of skill, as it would not do to do the work in a slovenly manner, but it is time well repaid in the end. It may be thought that bottom-heat is necessary to start the newly-potted plants, but with careful watering and a suitable temperature the growth will be all that can be desired without bottom-heat. Good potting material is important; this should consist of good fibry loam. I prefer that which has been stacked some time, with a layer of manure between the turves. Some mortar rubble and quarter-inch bones should be mixed with the soil, and during the growing season frequent dressings of Thomson's Vine Manure be given. I need not go into the composition of soils or manures, as each one should be allowed to use what he thinks best. Soils often differ greatly both in quality and texture; some require more feeding or addition than others, some require charcoal or bones, others are not deficient of lime and do not require lime rubble, but in all cases it is important to have the compost mixed some days previously to using to get it of a suitable temperature and in a dry usable condition. In a few instances Vines are cut back the third year, and of course then require much room, but this is not the system usually carried out. If a bit of fruit is required I would advise potting on the first season into 10-inch pots, thoroughly shaking out the next and repotting finally into 16-inch pots. Of course to do this the eyes must be

struck early, the strongest plants selected for the potting in during the summer, and the ripening of the canes attended to, and the Vines started as advised the next January to get them well matured. The system of planting young canes struck from eyes the same season is often carried out here; the roots have little or no cramping in pots, as before the roots get matted they are planted. This cannot be practised in some houses, and in these cases where strong Vines are used they require the same preparation as pot-Vines. I would also adopt the same principle in planting—that is, to thoroughly shake out the old soil and spread out the roots in preference to planting the ball with roots matted all round it. By the last system growth, no doubt, is quicker at the start, but the roots spread out as advised will furnish a better and stronger cane at the end of the season. I have often seen Vines planted with balls intact refuse to swell, and remain in a poor condition if the roots are in an impoverished state, having been in the pots for a long time. When selecting eyes either for pots or planting the same judgment is necessary, as when selected from hard, short-jointed ripened wood a good start is secured; all wood of a coarse pithy growth should be rejected. During growth the use of liquid-manures should be omitted till the pots are full of roots, and excess of manures in the potting-soil causes a rank growth, so that this should be avoided. I prefer it incorporated with the turf the previous season. W.

7180.—**A cool lean-to vinery.**—Black Hamburgh, Black Prince, or the Buckland Sweetwater—any of these would be suitable; but on the whole I should prefer the latter as more likely to do well so far from the glass. You can grow a moderate number of pot-plants in the front stage as well as the Vine successfully, but take care to keep them perfectly clean, healthy, and free from insects, and do not employ more heat during the winter, while the Vine is at rest, than is actually necessary. —B. C. R.

—If by the front staging you mean that which runs along the front of the house, you may like to proceed with a Black Hamburgh Vine on the back wall; but if the staging runs near to the back wall you are not likely to do any good with any sort of Grape. Black Alicante will do better than any of that colour. Its flavour, however, is only third rate. The Dutch Sweetwater is far preferable in regard to flavour, only the bunches and berries are small, but it will do better on a back wall than any other White Grape. —J. C. C.

—The Black Hamburgh will answer the purpose best. If planted against the back wall, it might be permitted to come a short distance down the roof. If you planted a second Vine

(and there appears to be room for two if a part of the roof can be given up), the Alicante would do, and would give Grapes later. Plants are and may be grown in vinerias. There should be no difficulty in your case.—E. H.

THE LOQUAT (ERIOBOTRYA JAPONICA).

ALTHOUGH seldom grown as a dessert fruit, this Japanese shrub is well worthy of culture wherever space can be afforded it in a cool-house, for being nearly hardy it only requires slight protection to keep it safe through the winter; in fact, in mild districts it might safely

Flowers and fruit of the "Loquat."

be grown on open walls in ordinary winters; but, like most of our fruit-bearing trees, it flowers early in the season and would probably require protection from spring frosts as much as from the cold of winter. I once had a large tree planted in an orangery that every year produced perfect fruits, ripening well, and they form an agreeable change in the dessert, as it is very pleasant to the taste. Apart from its fruit, the Loquat is well worth cultivating as a fine foliage plant, the leaves being very handsome, and as an evergreen for a cool-house. It thrives in a soil such as Oranges are usually planted in, and the two may be grown together. It is an excellent subject for covering a wall in a glass-covered corridor, and would doubtless be very fruitful in such a position if it could get light and sun-heat. The flowers are white, borne in bunches at the top of the shoots, and they usually set from three to five fruits in a bunch; each fruit contains a large seed like a Bean, by which means it may be propagated, or it may be grafted on Quince-stocks like a Pear. J.

5188.—**Pear-trees not fruiting.**—Pear-trees are so often in the same condition as yours when trained to walls, that it is a perplexing question to answer in a satisfactory manner as to the cause of their unfruitfulness. I believe the only explanation to be that the position is not suitable for the variety grown in it. As I have known when such trees have been regrafted with another sort that they have been as fruitful as anyone could desire, and when this process fails to convert barren trees into fruitful ones, they should be taken away and some other kind of fruit-tree put in their places.—J. C. C.

—If the root-pruning four years ago did no good it was carried far enough. Root-pruning rarely fails to throw the trees into bearing when properly done. The Jargonelle on some soils is rather a shy bearer. The main roots are probably deep now; these roots must be got at and shortened.—E. H.

—Perhaps the root-pruning was not satisfactorily carried. It is useless doing this if the tap-root, which grows direct from the base of the tree in a downward direction, was not severed. The end of September is the best time for root-pruning, but it would be better to do it now than not at all, or even wait until next year. If the trees are large take out a trench 4 feet away from the stem, and as wide as will admit of a man working in it comfortably. Cut off all roots coming in contact with, and gradually work under the tree at the bottom of the roots until the wall is reached, to make sure the tree has no tap-root. Fill in the trench, treading the soil firmly if it is not wet and heavy

to run together. Perhaps the trees were planted too deep; in that case it is useless going to the trouble of root-pruning; better to replant them. If they are too large for this, raise the roots within a few inches of the surface. Do not mix manure with the roots, but lay it out on the surface as a mulching, 3 inches thick, if the tree is replanted, but not if it is only root-pruned. Are the blossoms protected from frost? If not, that would be sufficient to account for the absence of crop perhaps. It is always wise to afford protection to wall fruit-trees when in bloom, either by hanging a double fish-net in front or a temporary protection of evergreen houghs suspended to the front of the wall, just while the trees are in bloom.—S. J.

5192.—**Pear-trees not bearing.**—The flowers are imperfect from some cause. Is the position a dry one? The mention of hot pipes has raised the thought that the roots are at times too dry. I should be disposed to try some liquid-manure. There is weakness from some cause.—R. H.

LATE PLUMS.

PLUMS get into bad repute with those who grow for profit by glutting the market whenever there is a good crop, and the prices going down so low as not to pay the expenses of gathering; but this only happens with the mid-season kinds, like Victoria, that are so excessively prolific that they cannot be consumed all at once; but I never knew a glut of late Plums, and the following kinds may safely be relied on as the cream.

COE'S GOLDEN DRUM is probably one of the richest flavoured and best Plums in cultivation, and no matter how plentiful early Plums may be, there is never any difficulty in getting a good price for these. With us they fruit well as bush-trees, but will repay for a wall, and require hanging at least until October before they are fully ripe to get their best flavour, and they keep well if gathered and stored in a dry, cool place. A good dish of Coe's is a great point in collections of fruit at Chrysanthemum and Fruit Shows usually held early in November.

GRAND DUKK is one of Messrs. Rivers' additions to the list of late Plums, a good grower, and very prolific; a rich-flavoured Plum; makes a good companion dish to Coe's Golden Drum.

IMPERATRICE (blue), one of the good old kinds that require a wall, when it may be kept very late by placing tiffany over the trees to keep off early frost. It is lost when partially shrivelled.

RIVERS' LATE, a round black Plum, of medium size, very juicy, and rich flavoured, a very useful kind for kitchen or dessert purposes.

WYDALKE is probably one of the latest of all Plums. I was surprised to see good fruits hanging on a tree after the severe wintry weather we experienced on November 18th, the fruits being still plump, and excellent for kitchen purposes. The tree had yielded an enormous crop. J. Groom, Gosport.

5169.—**Dahlias for show.**—A good selection of twelve show Dahlias would comprise the following: Benldige (a well-shaped flower of a purple-crimson colour), Lunary (yellow, very pleasing), Ethel Britton (blush, with an edge of red-purple to the petals), George Rawlings (rich maroon), J. T. West (yellow, the petals tipped with purple), Harry Keith (rose-purple), John Wyatt (rich scarlet-crimson colour), Mrs. Glasscock (pure-white), Mrs. Chelstone (a lovely colour, silvery-pink, very pleasing), Queen of the Belgians (cream colour, the inner surface of the petals delicate pink), Rev. J. Goodhy (maroon, with purple suffusion), and Wm. Rawlings (crimson-purple, a rich shade of colour).—C. T.

5171.—**Peat Moss-litter for stiff land.**—Yes; on the lower side we have to deal with it, and this is even superior to the ordinary atmosphere, either worked into the ground or applied as a mulch. I have not used it to any extent for hot-beds, but do not see why it should not answer for this purpose also.—H. C. K.

—Peat Moss-litter-manure is good for stiff land, but is not so well adapted for hot-beds, as it contains nothing to bind it together. Will do very well for filling pits for Cucumber or Melon.—E. H.

5188.—**Drooping Fuchsias.**—The old Mrs. Marshall (white and rose), Coreud Garden (white), Mrs. Grote and Danden (all light-coloured singles), with Gen. Roberts (dark single), and Miss Lucy Ellis, Fran E. Tojler, and Lord King (doubles, with white or blush colour) are among the best with a drooping habit of growth.—B. R. ILLINOIS AT

FERNS.

ADIANTUMS IN WINTER.

THESE Ferns require a period of rest, and in none is this more evident than in *A. cucullatum*. Plants which have been growing freely during the latter part of the summer and autumn should be well exposed, and when the fronds are well matured the cooler the plants can be kept the better. If gradually hardened off and kept fairly dry in the pots, they will keep well where the temperature does not fall below 40 degs. Fahr., the fronds changing to the pale-green hue which is now so essential, or, rather I should say, which florists consider essential. It is no doubt owing to the fact that they have found the pale-green so much more durable than the deeper green fronds that the change has been brought about. For early spring use another batch of plants should be grown; these should be kept in cold-pits and as dry as possible without injury to the roots. They may then be started in warmth late in the autumn, and under fair conditions will make good fronds, and either for cutting from or as pot plants will come in for use about February and March. Like those for autumn use, these should be hardened off after the fronds are well matured. I find it is of little use to try to get good results from plants which have been kept in a growing state throughout the year; the growth there will make during the last three months of the year will be weak and imperfect, and they will also have become so exhausted that it will be late in the spring before they will make any good progress.

AD. ADIANTUMS should be kept moderately cool and dry at this season, and will then, if given a little more warmth, start away and make good growth as soon as the days begin to lengthen. Where the pots are well filled with roots a little artificial manure may be given occasionally while they are growing. Although *A. cucullatum* still holds first place among Maiden-hair Ferns for decoration, there are several others which are for many purposes preferable. *A. elegans*, which has large and more spreading fronds, is now extensively grown. It appears to be hardier than *cucullatum*. Young plants are a little loose and straggling in growth, but the second year they fill up and make fine plants, growing taller than *cucullatum*. *A. Williamsi* is also a valuable kind for cutting from when grown under cool treatment, but in warmth the fronds run out too long and thin. Of course, for cutting from the fronds should be well matured, but if too old, the pinnules drop off soon after the fronds are cut. I often wonder that *A. cucullatum* does not come more into use for cutting, the large spreading fronds being very effective and also lasting longer than those of most of the Maiden-hairs. In the spring this makes a very pretty plant for decoration. Plants grown in a light open position have a very pretty tint in the young fronds. There are two varieties, one having a pale-bronzy tint with only the slightest shade of red, while the other has a beautiful rose-red tint, and with age the fronds change to a deeper green. Though this is generally known as *scutum roseum*, I believe it is identical with the true *A. tenerum*.

A. LATHOMI, which is closely allied to the above, but has more drooping fronds of a pale shade of green, may be recommended, but is not so easily propagated as most of the *Adiantums*. Of the smaller growing Maiden-hairs, *A. minutulum* is the most useful. It makes a very compact and pretty plant, and the fronds are of a useful size for button-hole bouquets or any other purpose where perfect little fronds are desirable. This is sometimes confused with *A. Pacotti*, but it is quite distinct, the fronds having smaller pinnules, which do not overlap each other as in *A. Pacotti*, which is sometimes recommended, but is too dense and heavy for most purposes, though it makes a very pretty pot-plant. In winter this requires some care, as it is much inclined to damp off. The plants should be stood up on pots and have sufficient room for the air to circulate among them, and in watering care should be taken not to wet the fronds.

F.

5172.—A scented Fern.—This is a native species known as *Lastrea annula*, or by some botanists as *Asplenium annulum*, a sub-variety of *A. apiculatum*. It is, I believe, to be found wild in some parts of the country, and can be obtained from most hardy plant nurseries. —E. C. R.

BIRD'S-NEST FERNS.

THESE plants are easily grown into large, handsome specimens; their roots require good and careful drainage, because if this becomes clogged the chances are that the plants will throw up deformed fronds, which spoil their beauty, and render them eyesores instead of ornaments. The soil must be made sandy, and should consist of light, turfy loam and peat, with some leaf-mould and good sharp sand.

A. NIDUS (Thamnopteris Nilus, Neottiapteris Nilus).—This is an interesting East Indian species, which is popularly known as the Bird's-nest Fern, from the remarkably peculiar manner of its growth, produces entire fronds about 30 inches in length and 4 inches in breadth, which rise up from the crown, leaving quite a hollow centre at their base, formed by the fronds of equal breadth throughout, growing horizontally at first before taking up their upright course, thus leaving a large, open centre.

A. NIDUS AUSTRALASICUM.—This fine ever-green plant (here illustrated) is a native of New South Wales, and may possibly be only a variety of the preceding species, from which it differs greatly in its fronds being of larger dimensions and of an elliptic lanceolate shape, instead of being of a uniform breadth. Besides the above characters there is one point essentially distinct; the fronds, instead of growing horizontally at first, are produced all round the rhizome and take an upright direction at the first start, so as to leave the crown elevated and exposed, thus making the hollow centre more funnel-shaped. Both this plant and the above species are wonderfully well adapted for vases, for which they make splendid objects. Although requiring stove-heat to grow and develop properly in during the best part of the year, *A. Nidus australasicum* will stand very well outdoors in the summer-time if not exposed to the full sun. Great care should be taken to keep away slugs and woodlice, which are exceedingly fond of the young fronds; the best way to prevent these pests getting at the plants is by placing the latter over a pan of

protection in winter and suitable material for the new roots to start into in spring. Grasses and other herbage also assist in protecting the crowns during the winter. It appears to me that many who try to cultivate hardy Ferns forget that they are depriving them of the protection they find under natural conditions, and, consequently, do not succeed. Of course, it is not necessary to allow Grass and all kinds of weeds to grow up among the Ferns, yet something should be done in the autumn to make up for this deficiency. A good mulching of leaves may be recommended; either new leaves or those half-decayed may be used. I prefer the latter, as they provide more nourishment for the young roots in spring. And besides this, if the plants are much exposed, they should have a covering of dried Bracken or other light material. Bracken is about the best thing that can be used, as it will gradually decay, and by the time the Ferns start into growth the young fronds will be able to push through. Spring frosts are often destructive to hardy Ferns. Many of our British Ferns are worthy of cultivation under glass, more especially the beautiful varieties of the Lady Fern. The exquisite beauty of *Athyrium (Asplenium) Filix-foemina plumosum* is not excelled, if equalled, in any of the exotic Ferns. When grown under glass care should be taken not to excite them into premature growth. Although a little heat will do no harm in the spring while they are making their growth, giving them warmth during the autumn and early part of the winter will excite them and materially weaken them. Some of the hardy Ferns may be kept in warmth during the winter without suffering much. I find that many of the hardier exotic Ferns will also suffer much if kept too warm during the autumn, though they will grow well in the stove during the spring and summer.

H.

Alder for hedges.—As a hedge plant, the Alder is not an good as the Poplar. It delights in wet, swampy lands, and will grow

The Australian Bird's-nest Fern (*Asplenium Nidus australasicum*.)

water on three inverted pots, so as to prevent the bottom of the pot touching the water, but at the same time leaving a liquid barrier of 2 inches all round to keep off all intruders.

G.

HARDY FERNS IN WINTER.

MANY of our most beautiful hardy Ferns suffer if fully exposed during the winter. When under cultivation it often occurs that they do not get the shelter (on they find in their natural habitats. The leaves from deciduous trees provide both

tolerably even in the water. The plants (for fearers should be four years old, not more, because when older they are generally devoid of branches at the bottom. They may be set at a foot apart, and treated in every respect like the Poplar, trimming the fence with a hedge-bill, and keeping it at the height of 5 feet. The Alder will make a strong, branching fence, though not very close, and if pruned regularly as directed, it has a neatness much beyond what is generally believed of it. Few have the courage to keep it in subjection, being a tree of extraordinary substance. —E. C. R.

ROSES.

ROSES FOR PILLARS, ARCHES, AND PERGOLAS.

There are forms of culture where the extra strong Roses show to great advantage—when used for the purposes suggested by the above heading. Roses grown for this purpose are much exposed to the extremes of heat and cold, unless they are in some well-sheltered spot. Although all of the hardier varieties are suitable for sheltered situations, there are a few which are much choicer in colour and scent and that may be safely grown in warm localities. A pretty effect is gained when a well-planned pergola is covered with suitable Roses. We have two points to aim at—a gorgeous display during one month only, or a successive display of less splendour more or less for six months and upwards. Which is it to be? All depends upon the selection and pruning, and more upon the former than the latter. My own taste goes towards a continuous feast, when the full beauty of the several types can be enjoyed. However, as we do not all share the same opinions I will name a few sorts suitable for both results, and in order to assist in their colour arrangements will add their predominating shades. This is well worth a little attention, as the effect is considerably heightened by judicious contrasts. As I have already noted, we must choose our sorts according to the position of the pergola, and as the same remark applies to those growing upon pillars, arches, or walls, I will proceed to name a few of the hardiest varieties: Cheubant Hybrid, Reine M. Henriette, Brunette, Bruette Fridolin, Climbing C. Lefebvre Mme. I. Perière, and Gloire de Margottin, are all reds of various shades. Whites may be found in Miss Clegg, Aimée Vibert, Blanche de Forco, Boule de Neige, and Coquette des Blancs. The following are yellows in shades varying from that of the old Dijon up to an orange or apricot yellow as found in Wm. A. Richardson. Both of these are hardy and may be supplemented by Madame Birard, Bouquet d'Or, Henriette de Beauvean, Climbing Perle des Jardins, Kaiserin Friedrich, Emile Dupuy, Belle Lyonnaise, Gloire Lyonnaise, Duchesse de Mecklenburg, but Rêve d'Or, Maréchal Niel, and the Banksians need a more sheltered position. All of these will do for all purposes named, but for pillar Roses I like to get a few more of the brighter coloured H. Perpetuals, and such ever-blooming Teas as Marie Van Houtte, Anna Olivier, &c. These will soon cover a pillar, and are equally hardy with the Hybrid Perpetuals. Strong growers naturally need more support as regards fertilisers, and the soil should always be rich, either from suitable dressing or naturally. Pruning does not consist of much spring work, except the removal of any dead or frost-injured wood. During the summer a few of the branches which have already bloomed may be cut away to make more room for the succeeding growths, but this will not be so necessary as when upon walls, where we have only one side to consider. The growth over a pergola will also be pleasing in itself, and often prevent much knife work, except to do a little judicious thinning in the autumn when clearing up for the winter.

P. U.

5186.—**Roses and Carnations.**—Unless you can give the house up entirely to the Roses, it will be better not to plant these out, but grow them in good-sized pots, removing them outside for the summer. The Carnations will, of course, be grown in pots, and the Tree or Perpetual varieties will be found more suitable than the ordinary kinds. As regards temperature, the more heat (in reason) is employed the earlier will the Roses produce their flowers—that is, provided the plants have been properly prepared; but if the night temperature exceeds about 55 degs. at night it will be too much for the Carnations, so that this should not be exceeded, if possible.—B. C. R.

—Certainly these may be grown together, but I would not advise your trying to get early bloom of both at the same time. To do this, it would be necessary to provide a much stronger heat for Roses than the Carnations would approve. For your guidance I will describe a small house I have filled with both in all-arcin pots. During August and September all

were out-of-doors. In October the Carnations were housed. These consist of the Tree or Perpetual-flowering section. In November, and at present, they produce good flowers, and will continue until February and March. My house had all the air I could afford, and was only partially closed upon bad weather. Even when frosty there was a little top ventilation afforded, with just a dash of fire-heat to keep the air rather dry. My Roses are now pruned and brought into the same house. They stand rather thickly in the centre of the benches, being surrounded with the Carnations. A very gentle fire-heat will be kept up for a short time longer, then gradually increased until it reaches 55 degs. to 60 degs. by the early part of March. By this time the bulk of the Carnation flowers will be secured, and I shall stand the plants into a pit or frame until they can be turned into the open borders in May or June, when they will be layered and grown on for potting up in September, ready to go through the same routine again. By the time the Carnations are moved, the Roses will need all the room and be in flower in a week or two. The fumigation and syringing necessary for Roses while making their growth is just the thing for the Carnations before being removed from the house. The two also work well together as regards heat, a cool temperature being best for the Carnation and also for the Rose while starting into new growth. When the former are out stand the latter farther apart and allow a rise of 10 degs. This, with careful syringing, will give you good Roses in quantity during early spring. In August stand the Roses outside, and do what potting may be necessary. Then place in a pit until the beginning of the year. I know of no two flowers which work together in this way better than Roses and Carnations.—P. U.

5190.—**Forcing Roses for cut blooms.**—In the first place, I do not see how you are to force Roses early with only a flow and return 4-inch pipe in a house 16 feet wide; that quantity of piping is barely enough to keep out frost in severe weather, much less maintain a forcing temperature, as it is not unusual to get 16 degs. of frost in the month of March. I should say the middle of February is as soon as it will be safe to begin forcing. The next point is the way in which you intend to grow the Roses. I gather from the information you send that you are thinking of growing them in pots. But are you aware of the amount of labour that involves the whole year through in watering and other details? In such a case as this either the Roses or Tomatoes should take a secondary position, whichever is likely to pay best. I work my houses on these lines. All my Roses are planted out in borders inside the house, and as soon as the first lot of blooms are over on the Roses the growth is cut down to near the stem, and then the Tomatoes take their place on the roof. You must, however, understand that I do not get a full crop from the latter, because the growth has to be gradually cut away to allow of the young shoots of the Roses being trained under the glass as before. My houses are, however, efficiently heated, and the warmth given to bring the Roses into bloom by the middle of March is sufficient to get the Tomato-plants in flower early in April. I do not know of a more economical way of growing these two subjects in the same house, as you will understand that, except to thoroughly moisten the border in which the roots are growing, my Roses are really not much trouble.—J. C. C.

—The greatest difficulty in occupying the houses with Roses and Tomatoes will be found in getting wool of the former sufficiently vigorous and finished before you need the space for the latter. You want Roses during the first quarter of the year, and Tomatoes in the house by April. If your houses are fit for Tomatoes, they would be more suitable for the strong-growing climbing section of Roses than for those of Mme. Falcot and Catherine Mernet type. To have the former good year after year it would be necessary to keep the young shoots from the base growing freely and vigorously until July at least; therefore, it would be prejudicial to shift them to the open so early, as would be useful if Tomatoes are to occupy this space by April. I note that you have six houses, each 40 feet by 16 feet. Why not devote all of them towards finishing off the Rose growth and as shelter to the Rose-plants for the first

six weeks after being restarted? I would suggest the following routine. Consider your Roses have bloomed by the early part of April, then cut back the wood which bore flowers and remove the whole of the plants to the two houses, growing the young rods up the roof much in the same manner as Vines. You can thus attend to their wants and secure really valuable wood for next season's forcing. The advantage of full ventilation can be afforded for a short time previous to removal to the open as a finish to their ripening. In October they should be housed again and started as steadily as possible. Here they will push into growth of an inch or so by the end of the year, by which time the other houses will be quite clear of Tomatoes and ready to receive their quota of Roses. It is while growths with blooms are produced from each side of the long summer growths that this section of Rose requires ample room, and you would be able to fill all six houses to advantage, working young plants of Tomatoes on in the meantime. A steady temperature until the days have turned, and then an increase when your plants are in their flowering positions, will soon give you a valuable return, and avoid the long spell of emptiness experienced when Tomatoes only are grown. I would confine myself to the following six Roses: Maréchal Niel, Climbing Perle des Jardins, W. Allen Richardson, Reine Marie Henriette, Climbing Niphetos, and L'Idéal.—P. U.

—Yes; properly prepared and well-ripened Roses in pots may be flowered and got out of the way by the end of April. The Tea-scented kinds would be most suitable (with Maréchal Niel and one or two other Noisettes), and a temperature of 60 degs. to 70 degs. would be necessary from soon after the turn of the year.—B. C. R.

5193.—**Roses in a small garden.**—It is hardly the correct thing perhaps to advise pegged-down Roses for a small back garden, yet for a position that is so much exposed to rough wind as this inquiry refers to, it is certainly the only form of growth that appears likely to give satisfaction. I think a few strong-growing Hybrid Perpetuals, like Charles Lefebvre, General Jacqueminot, John Hopper, Mme. Gabrielle Luizet, Magna Charta, Jules Margottin, Mme. Charles Wood, Etienne Levat, Duchesse de Vallombrosa, and Prince Camille de Rohan, with their strong growths pegged down on the ground, would suffer less from the effects of the wind than any other form that you can grow them in. If this does not meet with your views, you had better select sturdy-growing H.P.'s, like Baroness Rothschild, and grow them as dwarf bushes. Others belonging to this type are: Captain Christy, Merveille de Lyon, Crismon Belder, Victor Hugo, and Ulrich Brunner.—J. C. C.

—I do not recommend Roses to be grown in a very small garden—at least, not the Tea-scented varieties. Apparently everything in your garden seems to get blown to pieces, and Tea-scented or any other Roses will not stand this kind of treatment. I will, however, give you my experience of Roses in a small garden. I planted a bed of them last autumn in a garden situated similarly to yours, but the wind does not play such pranks as recorded by you. A good loamy soil composed the bed, and in the early summer a liberal mulch of manure was given. Throughout the summer the plants were freely watered when necessary, which was pretty often last year. All the following varieties succeeded well, and I hope this small selection may be of use to you, the plants being dwarfs on the Brier-stock. W. A. Richardson, well known for its exquisite apricot colour. This variety, contrary to my expectations, flowered remarkably well, and the plant is very strong. Of the Hybrid Perpetuals Duke of Edinburgh (crimson, tined with maroon, a full flower), Mme. Isaac Perière (rose-carmine), Boieldien (cherry-red colour), Eugène Appert (crimson), Mme. Gabrielle Luizet (pink), Mrs. John Laing (pink also), and Lady Arthur Hill (rosy-lilac). These have all succeeded well with me in a very small plot. I may mention that a Gloire de Dijon Rose planted at the same time has made splendid growth. This is a really lovely Rose, and indispensable in the smallest collection.—F. P.

—Your description does not sound very favourable for Roses. Can you not devise some slight protection against the strong south-west winds? A dozen hardy H. Perpetuals will be found in General Jacqueminot, Jules Margottin,

Baroness Rothschild, Annie Wood, Mrs. J. Laing, Ulrich Brunner, Duke of Edinburgh, Charles Lefebvre, Fisher Holmes, Comtesse d'Oxford, La France, Alfred Columb, and Dupuy Jamain. Teas: Marie Van Houtte, Anna Ollivier, Madame Lambert, Homère, Dr. Grill, Ernest Motz, Comtesse Riza du Parc, Souvenir d'un Ami, Goubault, Sunset, Safrano, and Perle des Jardins. If possible get a little clay or stiff soil and mix with your own, then apply whatever manure comes to hand, with the exception of soot.—P. U.

5194.—**Climbing Roses.**—If the long shoots on your climbing Roses are 9 inches apart they do not require to be thinned out. You may, however, take off a few inches of the soft tops at once, and at the same time cut back to the second or third eye the short growths. The plants in pots may be pruned now if they require it. The harder you prune the later they will flower. Probably the younger plants will be all the better for being cut down to within 9 inches of the pot. You had better keep the pot-plants on the floor of the house, and with a view to retarding them keep the house well ventilated both night and day, except in very severe frost—as a matter of fact, a few

varieties of Roses you have. Some of the Noisettes are not suitable for you, especially those that flower in large clusters, like Aimée Vibert. I should prefer to confine my selection chiefly to the Teas, and if given good culture, some of the old ones remain unbeaten for continuous flowering, such as Adam, Alba rosea, President, Letty Coles, and Isabella Sprunt. The greatest difficulty will be in getting flowers during the months of November and December. They are better obtained from plants that are rested in the open air from the end of July to the end of September. Before they are taken outside let them be pruned into shape, if necessary, and given larger pots. Until they are taken under cover again all the flower-buds should be picked off. The plants that are to flower after Christmas should remain in the open air, with the pots plunged in ashes until the end of November.—J. C. C.

— With thirty plants of these it is certainly possible to have bloom all the year round, but not in any quantity. I would arrange them in three batches, and in order to make the following notes more clear, we will suppose that at present they are all established in pots and quite dormant. Select the ripest plants of such

A GARDEN OF HARDY FLOWERS.

The outdoor garden at Edge Hall is remarkable for its fine collection of hardy plants. The hall stands on the side of a hollow watercourse worn in the stiff clays which in Cheshire often lie over the sand rock. The open space round the house is covered all summer with a dense forest of herbaceous plants—every ornamental kind which will thrive in the cold and damp soil on which the house stands being cultivated here. As for the rest of the garden and the many little rockeries on which choice alpines get unremitting attention, much information about them has from time to time been afforded in various gardening papers. The illustration herewith given shows well the beauty and value of bold groups of hardy plants.

Mimulus maculoeus.—I would like to remind readers that although seed of any choice strain of *Mimulus* is very small and may be thought tender, yet it is a very hard seed and rarely suffers from chill or damp. I always found that, sown either in December or January in a shallow pan, literally on the surface, of fine sandy soil and protected by a broad, clean piece of glass, germination even in a cool-house

OUR READERS' ILLUSTRATIONS: The Garden at Edge Hall, Malpas, Cheshire. Engraved for GARDENING ILLUSTRATED from a photograph sent by the Rev. C. Wolley Dod.

days of frost from now to the end of February will do them more good than harm, as it will keep them from starting into growth so early. With regard to the top-dressing of the border and those in pots the present time is very suitable for the operation.—J. C. C.

— You have grasped the right idea when growing Roses in unheated houses—viz., to keep them as backward as possible. As you truly remark, late frost, combined with damp, are often the cause of failure unless kept backward. It is a very good time to do the mulching as you propose. Cut away the side growths, and thin out any of the stronger ones where unduly thick. Next season confine each plant to two shoots, or, at most, three. The ordinary growing Teas may be pruned fairly hard, and then allowed to come on at will, but being subjected to the same cool treatment. I think, and sincerely hope you will be successful, as you are evidently well in the right track at present. Shall be glad to hear next spring.—P. U.

5184.—**Tea and Noisette Roses.**—By skilful management you may succeed in doing what you want, only from thirty plants you would not get any great quantity of flowers at any one time. Something will also depend on the

varieties that produce thin or few-petalled flowers—Madame Paleot and Safrano are examples—also one or two of the strong climbers which bloom most freely, say Marchal Niel and Reine Marie Henriette. These will be more amenable to hard forcing than others, and will soon come into bloom under such a temperature as you possess. This batch of ten or a dozen will flower during March, and must be grown on freely during that time and until June or early in July. If grown in the open air steadily for a time, and then encouraged to ripen early, these same plants may be introduced again in October, and should then be in flower during January of the next year. The second batch may be brought into heat about February this first season, but should be started about now after the first year. They will then come in when the late autumn-started plants are falling. Keep the third batch backward, and get them in bloom late enough to still throw a fair quantity until Christmas. With Teas this is not difficult, because they are late and almost perpetual flowerers. As the latter will be growing late, they can rest in a cool pit until late again the following spring. There will be great need for strict cleanliness if Roses are to flourish in the house from one end of the year to the other.—P. U.

or frame would result in ten days, and that it was thus too easy to have literally hundreds of seedling plants to put out in the open ground for summer planting so early as the middle of April. It is but needful to prick out the seedling plants thinly into other pans or shallow boxes when the seedlings are large enough to handle. In a month, perhaps, they will need still more room, and are then best planted out 4 inches apart in a cool frame. Here, protected partially from frost, the plants will make strong growth, and will be large clumps of several shoots ready to plant out in the open ground early in the spring. Really these *Mimulus* are half-hardy.—D.

Labelling plants.—A great deal of annoyance is often caused through the omission to make sufficient note of the whereabouts of bulbs and the smaller herbaceous perennials. I do not admire a lot of conspicuous labels; but neat ones with the names written plainly thereon will prevent the roots being disturbed or otherwise injured when forking over the border. Not only will you derive greater pleasure and interest from knowing the correct name, but a glance will show you where it is allowable to dig and where not. Many a future crop of some favourite has been quite ruined through the neglect of this simple precaution.—P. U.

THE KITCHEN GARDEN.

A FREE USE OF MANURE.

Those private gardeners who have not previously seen but little of what is going on in the market gardens and farms round London and other large towns are invariably impressed with their first glimpse into the ways of those working these. Especially are they surprised at the quality and quantity of manure that is used. As a rule, private gardeners fail to get enough solid manure, and in very many instances have to be content principally with what has previously done duty as hot-bed material. Very poor stuff the latter is, or little better than a mass of humus, and such ought always to be supplemented with fairly liberal supplies of chemical manures, that most generally needed being potash in some form. To all appearances market growers apply their cheaply-obtained and really good animal manure—the principal fertilising properties not being either washed out by rains or dissipated by undue fermentation—at the rate of not less than 30 tons, and not unfrequently nearer tons to the acre. The ground being in a good condition for receiving this, it both can and does produce enormous crops in close and rapid succession.

GOOD STABLE-MANURE, such as can be obtained in the neighbourhood of large towns and also any from a mixed farmyard, more especially where the fattening of beasts is going on, is as near perfect as can be mentioned. In this case it appears next to impossible to overdo the ground with this in a semi-decayed state, always provided the cropping is close and heavy. It is very different with the rotten stuff that has to do duty in very many private gardens. This contains but few constituents of a plant-sustaining nature other than moisture, and which humus both holds and absorbs from the atmosphere. In the course of a few years this kind of manure sinks into a clayey nature, especially those of a clayey nature, and this can best be corrected by a dressing of lime instead of manure applied at the rate of two bushels per square rod. The lime must be preferred is that obtained from the magnesia limestone rock, and this ought to be applied direct from the kiln. It can be most simply slaked by being laid in small heaps and covered with soil for a few days, and should then be spread over the surface of the previously dug ground and forked in. The effect of this dressing on manure-sick ground is almost magical. It has the effect of liberating food previously locked up, and enters into combinations with other constituents required for the invigoration and sustenance of vegetable life generally. It was not, however, my original intention to discuss the nature of manures, but rather to touch upon what crops stand most in need of—rich food at the roots. All things considered, the most liberal use of solid manure is advisable in the case of

GLOBE ARTICHOKE and **RHUBARB**, as it is scarcely possible to grow these too strongly. On dry, hot soils and poor ground generally, the former fails badly in a dry season, and at no time are the heads so large and succulent as desirable. For these crops, resort to trenching or double digging, mixing manure freely with both spits, while if the nature of the ground renders trenching impossible, increase the depth of surface soils by means of additions of compost in which strong loam and manures figure largely. In my case Globe Artichokes are of such importance, that I would deny any other crops solid manure in order to let the former have plenty both mixed with the soil and in the form of a mulching. Rhubarb is not nearly of such importance, but pays well for liberal treatment. Onions if wanted of large size must have plenty of solid manure in the soil in addition to soot and other manurial dressings, and even if medium-sized to small roots are preferred, it is advisable to make the ground rich, fineness of soil and thick cropping being the rest. Soot, in addition to being a good fertiliser, is also, to a certain extent, a preventive of Onion-grub. It pays well to well fork in half-a-bushel to the rod now and to apply another somewhat lighter surface dressing just prior to sowing the seed. It is an old custom to sow

Onions in succession, to Celery, the latter being sown up to the ground in the best condition for the reception of the former. Such

may be the case in some few instances, but, as a rule, Celery exhausts all the manure placed in the trenches, and the apparently finely divided state of the surface of the ground when levelled is altogether misleading. The surface may be perfectly fine, and just underneath patches of soil closely run together wet and cold be found. It answers my purpose to devote ground previously cleared of early and mid-season Celery to Onions, but advantage is taken of a frosty morning to wheel on a good dressing of manure, rough digging following as soon as practicable. Thus treated, the soil breaks down admirably at sowing time, invariably producing a good crop of medium-sized, firm Onions, and when the latter are cleared off very little further preparation is needed for spring Cabbage. If Carrots, Beet, Salsify, and such like, were to follow Celery, I would yet advise digging the ground deeply after the levelling has taken place, no animal manure being given, however. Contact with the latter and also masses of wet trampled soil buried well below the surface by the levelling process cause tap-roots to fork badly. These, therefore, should have a finely divided deep root-run, and if solid manure is applied it must be buried not less than a foot deep. It is a mistake to be too stingy with manure as far as

POTATOES are concerned. Doubtless market-gardeners somewhat overdo their dressings, contact with so much strong manure having the effect of impairing the quality of the crops. If such is not the case, how else are we to account for the bad quality of the bulk of market Potatoes as grown in the vicinity of large towns? If good, solid manure is applied at the rate of 30 tons to the acre, this being dug in now where the land is of a heavy nature, and not distributed market farmers' fashion along the drills at planting time, the Potatoes will get the full benefit of this, and leave the ground in splendid order for any member of the Brassica family or Strawberries. Gardeners having nothing but poor rotten manure to wheel on to their Potato ground ought to supplement this at or near planting time with either soot, guano, or superphosphates and kainit. Well-decayed garden-refuse, in every five loads of which one load of fresh lime has for some time previous been well mixed, is one of the best manurial dressings that can be applied by way of a change to Potato ground.

PEAS, BEANS and **BROAD BEANS** must have plenty of manure under them, or they are liable to fail badly in hot, dry weather. The manure dug in ought also to be only partially decayed, as I have repeatedly found that where old but not very rotten manure has been used, the former especially has been badly attacked at the roots by eelworms. When once the latter make their home in the roots these become greatly swollen, and both root-action and top-growth are quickly paralysed. Wood-ashes mixed with the manure and very lightly sown with the seed is a preventive of insect attack at the roots, and also acts as a powerful fertiliser. Sown too freely with the seed it is liable to cause the latter to decay, and the soil in the drill ought only to be just whitened by dry wood-ashes at sowing time. Kidney Beans will thrive well for a short time on unmanured ground, and produce heavy crops if they succeed a crop for which manure was freely dug in.

CAULIFLOWERS revel in a rich root-run, the strong fresh manure dug or ploughed in by market growers suiting them well. To have them extra fine, or say fit for exhibition, manure should be freely dug in and liquid manure given in large quantities when the hearts are forming. If Brussels Sprouts are given good room and a moderately firm root-run there is not much likelihood of too much manure being applied at the roots, and the same remarks apply to Broccoli generally. Broccoli, Chou de Burghley, and Savoys I prefer to plant in succession to Leeks, Strawberries, or any other crop for which manure was freely used, a moderately rich, yet firm root-run best suiting this class of winter vegetables. H.

5104.—Size of a Tomato-house.—As to length it all depends upon the quality of plants you require; but a small house might be 12 feet long, 6 feet wide (lean-to house), back 30 feet high; front, 2 feet high, with bottom 30 feet to open. The steeper upright the roof the better it answers. I saw a house this season

of the above dimensions completely loaded from bottom to top with very fine fruit, some ripe and others green. The plants were planted one foot apart, and trained up roof on a single stem.—E. Vokes, Kingsworthy.

TOMATO-GROWING IN BOXES.

There is no denying that the demand for good home-grown Tomatoes still increases. It is true one sometimes sees a good crop in the open air, but this is often the exception than the rule. This being so, I content that everyone who has a demand for Tomatoes should endeavour to grow as many as possible under glass. During the last four years I have had a regular supply of Tomatoes from under glass from May to the following February. This has been accomplished in a large degree through adopting the plan of growing these in boxes, which have many advantages. First, they can be placed where pots often cannot. Every season I grow a good many in old wine cases. These are placed on shelves of vinerias or other fruit and plant-houses, where often pots could not be used. Early in the autumn I sow a pot each of two or three reliable kinds. As soon as the seedlings are an inch high they are placed in a temperature just high enough to keep them moving. Early in the year they are potted off. When large enough, about the middle of March, two or three plants are put into an old wine case; these cases are placed on shelves of vinerias wherever room can be found. As the days lengthen it is astonishing how they thrive in such positions. From these plants I usually gather early in May, and often afterwards continuously through the summer and autumn. I have a long Peach case. It is high, but only 8 feet wide; the lights push open in front. In this house I used to plant out Tomatoes wherever I could find room for a plant. When treated thus it was seldom I got any fruit to speak of; the generous treatment the Peaches received was too good for the Tomatoes, as they grew all to wood, and what did set was often too late to ripen on the plants. Last year I resolved to grow them in these shallow boxes. In this house I had a splendid lot of fruit, and when the weather became so cold that it was not safe to allow them to remain there any longer, I removed them into a late vinery, standing the boxes on the ground and placing a string strained to some sticks to tie the growth up to. Here they ripen off grandly and continue late. Some few years ago I remember calling at a market nursery near Farnham, Surrey, and here I saw two or three long span-roofed houses that were used in winter for storing bedding plants. In summer these were used for Tomatoes, which were grown in shallow boxes, I believe old egg cases cut in half. I am convinced that it is a mistake to grow Tomatoes in too much rich soil. I use nothing but heavy loam and burnt earth, at planting time just adding a few leaves at the bottom of the box. When the plants have set a crop of fruit, then I begin to feel, continuing it all through the season, changing the manure occasionally and sometimes adding a little fine soil with just a sprinkling of artificial manure. The boxes I use are of various sizes and depth, but the most of them do not exceed 10 inches to 12 inches.

5058.—Early Potatoes and Brussels Sprouts.—The distance apart at which the rows of Potatoes should be planted, depends on the fertility of the soil and the quantity of haulm natural to the variety. Some kinds with very dwarf haulm, such as Sutton's Ring-leader, need not be planted more than two feet apart from row to row. In this case the Sprouts should be planted two feet apart in the rows, other kinds of Potatoes, such as the White Hebron, when the soil is rich should have the rows placed four feet apart. This last season I made a bed of Brussels Sprouts and Potatoes in which the rows of Potatoes were four feet apart. I never had a finer bed of Brussels Sprouts, and as to the Potatoes, I never before grew any nearly so large. Under one root I found two tubers that weighed 3 lb. 10 oz. and 3 lb. 6 oz. respectively. I should state that these tubers were of bad form. The heaviest I had fit for the exhibition-table, was 2 lb. 6 oz. It might interest some readers that "go in for" growing large Potatoes if I say how I grew

them. I bastard trenched the land, putting a thick layer of material from the rubbish-heap on the bottom of the trowel spit. When I planted, I used whole tubers about the size of hen's eggs, having first removed all the eyes but one from each tuber. I placed them about three feet apart in the rows. When they were ready for earthing up, instead of doing this, as the weather was so very dry, I put in a layer of rotten manure about 2 inches thick over the whole bed.—L. C. K.

CABBAGES AND THEIR CULTURE.

THE cultivation of spring and other Cabbages, however simple it may appear, concerns the majority of gardeners who have to supply a household. Coming in when other vegetables are scarce, the earliest heads are anxiously looked forward to, and rarely afterwards, where abundance of choicer vegetable are grown, are Cabbages allowed on the dining-table. Not that later batches should be despised in the smaller gardens, as during a genial growing season the quality is anything but unsatisfactory. The smaller side sprouts after the main head has been cut are generally, where growing on well-manured and worked ground, of the highest quality, being very tender and of delicious flavour, and are often preferred by many people to even the main heads themselves. With our improved early varieties the cutting is quite a month or six months earlier than when we had to depend upon the larger-growing varieties. This is not the only advantage, as the sowing is even hurried out a month or three weeks earlier, which is another advantage, as the plants can be put out earlier and become well established before the cold weather sets in. On

CLAY SOILS this is of the greatest benefit, as those who may have to deal with such ground are well aware, as upon the advent of wet weather planting is carried out with difficulty, and often seriously delayed. When such as this happens the plants cannot become established, and upon a spell of frosty weather the plants are often killed outright. As regards the quality of even any of the varieties, there cannot be any comparison between those growing on well-manured and worked ground, and others on soils of the opposite description. Some people think any kind of preparation will be suitable, with the result, if the ground should be in a poverty-stricken condition, that the produce will be very poor in quality, consequent upon the lengthened time the heads took to come to maturity. Under such treatment Cabbages are emaciated, and probably rightly so, but given a generous diet and a well-worked plot, the quality should suit the most fastidious. The middle of July is now looked upon as being a suitable date for sowing for the earliest cutting.

Fig. 1.—Cabbage "Large York."

an extra week or fortnight's limit being allowed in the earliest districts.

SPECIAL DATES FOR SOWING in many instances are hard, and from August 16 to 20 is by many considered the best time for sowing. No doubt this would be correct if the older varieties were relied upon, but not those previously named, or even other good recognised varieties. The value of a bed of spring Cabbages is gauged by its earliness. As a safeguard against accident, plants from a sowing made about August 20 will be secure against any frost we are likely to experience and come in for making good any gaps or even for summer Cabbages. The mistake is often made of not raising nearly enough

plants for planting out, with the result that very small plants have to be used and which are in danger of being devoured by slugs. Seed is cheap, and a seed-bed need not occupy a great extent of ground. I do not favour thick sowing, as I consider this very unwise, and generally the forerunner of mishaps later on in the season. Bolting may be laid more to this source than sowing early. Nor do I favour sowing on poor ground, for the seeds are so slow in germinating and the aftergrowth so slow, as to cause a considerable check. The seeds being sown thinly in wide drills, sturdy plants are forthcoming and in

Fig. 2.—Cabbage "Winningsstadt."

cultivation for making a satisfactory aftergrowth. On sunny soils, especially in old gardens, clubbing is very prevalent, and where preventive measures are not taken, whole breadths, if not exactly cleared off, are considerably weakened by the attacks. In all cases a change of site is beneficial. Cabbages follow well after Onions. In those gardens which are subject to attacks of clubbing the old stems or clumps should all be cleared away and burned, thus destroying great numbers of the larvae.

DUNGHI in this old refuse is often resorted to where manure is scarce, and often where there is sufficient otherwise, but it is of more value when burned and the ash returned to the ground. Slugs and all such marauders as well as the larvae of root-eating weevils have their strongholds thus considerably weakened by this course of action. Good cultivation with a change of site is the panacea for this destructive pest amongst Brassicas. A free use of soot and lime is also a good preventive measure and should be resorted to, this being lightly forked into the ground previous to planting. Dusting the young seedlings with wood-ashes or powdered charcoal is also a commendable practice, and, previous to planting, all excrescences should be pinched off, these invariably lodging a maggot. The precaution of dipping the roots in a puddle formed of soot, lime, and soil in equal parts should also be taken. Any plants left in the seed-bed for future planting should also be lifted and undergo the same process. When ready for planting, the smaller-growing varieties should be set out 18 inches apart in the rows, with the same distance between. In the case of the larger growing sorts 2 feet is necessary. On light soils I prefer planting in deeply drawn drills, but on heavy soils on the level. A free use of the hoe will greatly assist in forming a good plot of Cabbages. Upon the approach of the early spring months, when growth is recommencing, a little guano sprinkled about each plant and hoed in will hasten growth considerably; so will also a light sprinkling of nitrate of soda, this latter being an excellent stimulant. The least sign of a blue tinge appearing in the foliage is a sure signal of assistance being needed. Excellent sorts to grow are Ellam's Early, Large York (Fig. 1), Nonpareil, English Market, Winningsstadt (Fig. 2), and St. Denis (Fig. 3).

5131.—A large Tomato.—I grew the Tomato Pomerosa last summer. From one plant I gathered a fruit weighing 13 1/2 lbs. I did not have the plants sent me till very late in the season; but you must not expect a quantity of fruit this size from a single plant. I grew it in a pot in a cool cucumber-frame. I believe if planted early it would grow very much heavier than the one above stated. Colour, a light-salmon. Fruit contains but a very few seeds. (C. O. H.) One seeds in three fruits.—E. VOYLES, King's Worth.

SEED POTATOES IN WINTER.

A good deal of discussion goes on as to whether we should use whole or cut sets of Potatoes, but my impression is that a good deal more depends on how these are kept during the winter. Potatoes for seed must be kept out of the reach of frost, but need not be excluded from light or air, as is the case with Potatoes for cooking; but the difficulty is to get space for storing a sufficient quantity of seed, where it is safe from frost, and yet not so warm as to excite growth. I keep a quantity of both early and late sorts, and the early kinds, when quite ripe and fit for storing in July, and unless great care is taken they will grow out prematurely, and a good deal of the strength of the tuber will be lost. I have lately sorted them all over, picking out all the sprouts and bad tubers, and then spreading them out as thinly as possible on shelves or floors of stores, keeping them open in mild weather, but covering with mats or litter if very severe frosts prevail. As a rule, I only pick seed Potatoes over once, for there are scarcely any diseased ones at all this year, and the sprouts they make after this date will not be any too much advanced for early planting. It is only when packed together thickly that there is any danger of the sprouting doing much harm, for if spread out thinly they will remain in a fit state for planting for many weeks. Keeping quite dry, as well as quite cool, is of the greatest importance. Anyone having only a small quantity of seed to winter in a small space cannot do better than pack them into shallow boxes, with not more than three or four layers of Potatoes in each, and set the boxes one on the other. They will keep dry, and the air will circulate freely amongst them, and in case of severe frost a mat will cover a good many boxes. J. G., Gosport.

Bush Marrows.—Although these varieties of Marrows are rarely found in ordinary market gardens, yet I have seen them in some small cottage or amateurs' gardens, where they are esteemed because they occupy but comparatively little room and are fairly prolific. No doubt one of the best is the once so highly favoured Cuckard Marrow, or, as sometimes called, the Elector's Cap. This is small, and most resembles a round pie made in a small basin or a deep saucer. It has thick, pleasantly-flavoured flesh, and should be cooked when the skin is quite tender, as it is not easily removed, owing to the peculiar shape of the fruit. The Geneva Bush Gourd is also prolific, and excellent cooked young. The fruits are round, flattish, and lobed, with green rim. It is a matter for surprise that by intercrossing with Pen-y-llyn, Moore's Vegetable Cream, or some other of the best and most prolific of the

Fig. 3.—Cabbage "St. Denis."

trailing varieties, some intermediate sorts have not been produced that are worthy of general cultivation.—A.

PLANTING EXPOSED GROUND.

CURVE OF TREES.—Next to the best method of planting exposed and hillside ground, the kinds of trees best suited for withstanding prolonged storms and the greatest amount of cold will be a matter of first importance. What should be aimed at first is to lure the outer boundaries of the plantation composed of trees that have proved most suitable for doing battle with the wind. The southerly and south-western boundaries are usually in this country those that suffer most, but the particular lie of the ground and adjacent hills may have much to do in deciding this important point. However, in any case it is just as well to ensure partial safety by gleaning the woodland from every side, and the best means of so doing will now be considered. The outer line or lines should be composed mainly, if not wholly, of such well-tried and valuable subjects as the Scotch, Austrian, Corsican, and mountain Pines (*P. sylvestris*, *P. austriaca*, *P. Laricio*, and *P. montana* or *P. Fumilio*), interspersed with the common Sycamore (*Acer pseudo-Platanus*), the winged Elm (*Ulmus alata*), the shaggy Hornbeam, Alder and such-like trees; while amongst these, and so as to make the ground thick with vegetation, the common Gorse, Broom, and native Juniper will all help and succeed if the soil is at all good. How these particular trees have succeeded in a plantation that I formed on the flanks of an English hillside, and at nearly 1,000 feet altitude, might now profitably be discussed, for the old adage that experience teaches still holds good in our own time and particularly in tree planting. Amongst the

THREE PINES—*sylvestris*, *austriaca*, and *Laricio*—there is little choice; indeed, they are all excellent trees for the work under consideration. I tried to make a choice of one over the other two, but here the *Laricio* seemed to stand best, while a little further on a fine green-leaved bushy Austrian asserted its right to supremacy for planting on the wild mountain-side. Then the Scotch stood so well out, even when in the very face of the worst storm, that I felt an injustice would be done to place any foreign species ahead of our own native and well-tried tree. There is something in the fact of one tree of a particular species—say, the Austrian—growing better than another of the same kind not a dozen yards away, and where both soil and atmospheric conditions must be exactly similar. To account for such a difference is indeed puzzling, and one might stand at the base of that wild craggy hill and look long and wistfully in trying to solve the mystery why such should be the case. No doubt the peculiar constitution of the particular tree has much to do with it, and this may be placed as a first reason; but there is a second that may not have occurred to everyone, and which for a few years, at any rate, would materially affect the growth of a particular tree—that is, injury to the roots before being planted, and which under ordinary circumstances it must take a long time to put right. There is still another supposition, or perhaps I should use the word affirmation instead, and that is that trees moved under peculiar circumstances, shelter being a prime mover in the matter, must and will be affected somewhat by a change to a totally different altitude probably so much apart as nearly 1,000 feet. This may be illustrated by a rather curious fact that came under my own observation in laying out the particular plantation to which I have referred. On the ground, or rather growing on a hillside at some little distance away, so as to ensure full justice being done on all sides, were several plants of the mountain Ash, Birch, Gorse, and Broom. Just as an experiment I had these carefully lifted and replanted in the plantation, whilst alongside these, others from lowland ground were inserted. To-day the difference in the two is very marked, the mountain ferns having kept ahead of the lowland trees, until now they have almost ousted them from the situation. There can be no doubt that acclimatization has a great deal more to do with plant life than we give it credit for. The sceptical may say that the conveying of the lowland plants for such a distance would materially affect them by loosening and shaking the soil from the roots, but I may just say that the trouble and value of the experiment were such that everyone who has had hillside planting to do must have noticed the difference at

growth between plants raised at high altitudes and those brought from lowland sheltered situations. The difference in growth between a strong

SCOTCH OR SCOTCH FIR and one that has been planted on the same high ground is truly remarkable, and leads one to the belief that were it otherwise practically, seed-sowing would be preferable to planting out. The Austrian Pine is a first-class tree for imparting shelter on exposed ground, its big massive branches thickly furnished with wind-defying, shaggy foliage, and adaptability to soil of a very poor description rendering it a most useful and valuable subject. There is an evil which I have heard sometimes spoken about, and that is that the tree is easily uprooted. This I have only found the case where big—too big—specimens have been planted out, but where the tree is used when only 2 feet or 18 inches high, the evil is considerably minimized, if not, indeed, got rid of altogether. There are few trees, coniferous at least, that do not suffer when planted at, say, the height of 6 feet to 8 feet, and this practice is, unfortunately, too common in small gardens and little properties. The Austrian roots shallow, we will grant, but so does the Scotch, and so does every Pine for that matter; but the root-spread is of the widest to compensate for the surface partiality. Then it may be argued that the timber of this Pine is not of such value as to ensure our planting the trees in question in any great quantity, and this is an unfortunate mistake that many fall into. A tree that will grow and live in positions where at times one can hardly keep his feet owing to the keen fury of the wind must not be condemned, for the very fact of its living and thriving on the windward side allows us to plant other trees that are less valuable in the same way to the leeward of it. Once a screen of the better trees has been got up, the interior of the wood may be planted with almost what you like. There can be no question that the Austrian Pine is one of the most valuable trees for shelter-giving with which we are at present acquainted, but that it is either equal to, or superior to, the Scotch or *Laricio* I do not feel inclined to say. W.

CRIMSON SATIN-FLOWER (BREVORTIA COCCINEA).

This name is now applied to *Brodiaea coccinea*, one of the prettiest California plants in cultivation. It is also a sure and free bloomer. It thrives extremely well in dry, well-drained borders, especially where deep planting is resorted to. It is also a most useful bulb for

Crimson Satin-flower.

pot culture, and as it is much showier than many of our spring bulbs, it is always an acquisition for that purpose. As a cut flower it is charming, so handsomely do the flowers hang over the edge of the glass in which they are placed. The leaves are about 2 feet long, narrow, and bright-green. The lower-stalk is about the same height, and bears an umbel of from ten to twenty drooping tubular blossoms, each about 2 inches long; their lower half is bright-scarlet, abruptly tinted with yellow, and the recurved lobes are green. It flowers naturally in May and June.

INDOOR PLANTS.

BEDDING PLANTS FROM SEED.

THE time for looking over the stock of bedding plants is now close at hand, and those who have to supply a large quantity from a limited space under glass will find it very much to their advantage to employ a good many that can be raised from seed, as it does away with a good deal of work in the early part of the winter, when the houses are crowded with *Chrysanthemums*, and when all the space is required for other things; but by utilising plants of an annual character that can be grown up to a good size by May, if sown in February the work is greatly simplified, as space can be made in pits, frames, &c., as soon as the days get out, and solar heat comes to the aid of the gardener. The following are excellent well-tried plants—

AURANTHUS MELANCHOLICUS RUBER.—A beautiful foliage plant for summer bedding, with very brilliant colouring; must not be planted out until the end of May.

CRANTHUS MELANCHOLICUS RUBER.—One of the most beautiful of silvery-leaved plants. The seed should be sown in pots of light rich soil in February, and placed in a warm pit until the seedlings germinate; then remove to a light shelf, close to the glass, and pot off in 3-inch pots as soon as large enough. They are nearly hardy when full grown.

DAHLIAS (SINGLE) are very showy in the flower garden, and seed sown in February and potted off in March will make fine plants for bedding out in May.

HELIOTRAPE, although generally propagated by cuttings, can in the event of being short of stock be increased readily from seed. After the seedlings are potted off they should be pinched at about 3 inches from the soil to induce a dwarf, bushy habit of growth.

LOBELIA (BLUE AND WHITE) increase readily from seed, which, being exceedingly small, require care in sowing. Fill the pots nearly to the rim with fine soil and sand, then water freely to settle the soil down. Shake the seed on the surface, and cover with a bell-glass. The seedlings will appear in a few days.

NASTURTIUMS OR THROLOZIUMS have of late years been greatly improved, being very dwarf in habit, rich in colour, and very floriferous. If the seeds are kept pinched off they make a brilliant and protracted display. They need not be sown before the end of March, and then only in a cool frame.

PRILLA NANKINENSIS, with a very dark leaf, makes a fine contrast where numerous variegated leaved plants are employed.

FETUNIAS (SINGLE OR DOUBLE) can be raised from seed. Splendid plants for dry seasons. The seed should be sown thinly in pots or boxes of light soils, set in heat in February, and potted off as soon as ready. They flower continuously through the season.

PULMONARIA is a very fine dwarf annual, and makes splendid beds, if sown under glass and pricked off into boxes of light soil, pinching the points out to ensure bushy plants. They should be planted out early.

PYRETHRUM (GOLDEN FEATHER) is one of the plants that cannot be expelled from the flower garden, being excellent for edgings and carpeting under taller growing plants. It may be planted out early in May.

STOCKS of the Ten-Week kinds are beautiful bedders, and should be sown in boxes of rich soil, set in cool frames, in March, the seedlings being pricked off directly they can be handled, or are very likely to dump off.

VERBENAS are very much more robust, if raised from seed than cuttings, and if seed is procured from a good strain, and sown in gentle heat, the seedlings will make fine bushy plants by May. They require pegging down to make them enter the bed regularly before flowering.

TARDES SIBNATA, a very small Marigold-like flower of rich golden-yellow, very floriferous. It is used as a substitute for yellow *Calceolaria* in places where they fail, but is more of an orange-yellow than the *Calceolaria*.

JAMES GROOM, Gosport.

Acacia lineata.—This is one of the few *Acacias* which are still fairly well known in private gardens in Britain, its survival after so many have disappeared being due, no doubt, to

its never failing to flower with great freedom even in a small state. Commencing to flower as it does, too, before Christmas, when the Chrysanthemum season is on the wane, its usefulness becomes all the more apparent. Like most of the Acaecias, it has a graceful habit to recommend it. The branches are long and slender and clothed with small linear leaves, to which the specific name refers. It belongs to the section of this genus which is marked by having the flowers clustered in spherical heads. All the flowers of cultivated Acaecias are yellow, and differ only as to shade, some being sulphur coloured, whilst others are almost golden. A. lineata is of a bright and moderately deep shade. To get this species to flower freely the pots should be plunged in ashes out-of-doors in a sheltered but sunny position during the summer months.—B.

WINTER-FLOWERING BEGONIAS.

These do not in some gardens find that favour which they deserve. It is probably caused by the rage existing for what may be termed cut material. They are not the best, I readily admit, for this purpose, but they are not had by a long way. They do not travel so well as many things, therefore that is also in a measure against them. When, however, the flowers can be arranged in water without any delay, they will stand very well. Grown as some grow these Begonias, in too much heat and moisture, is also against them. Even upon the plants then the flowers will not last nearly so long, this ensuing through the susceptibility to damping off; whilst if these plants are used for cutting, the flowers will not stand well. These Begonias require a drier atmosphere with some warmth, it is true, but not nearly so much as stove plants receive on the average. Where Cyclamens, for instance, are now flowering well with a gentle warmth, there these Begonias would thrive far better than in the stove itself. When the plants cannot be accommodated in a house to suit them, then the better plan is to grow them in pits, with a little air on all day in mild weather, and even at night also at such times rather than excite them with too much warmth. The roots must not be allowed to suffer, while, on the other hand, too much water must not be given them. The best safe-guard is well-prepared plants by previous good treatment in the summer, the plants having filled their last shift with roots. Late potting and over-potting are two decided mistakes, both tending towards a too suppy growth rather than flower. Plants more than two years old are not desirable unless they be grown for special purposes, as the covering of the walls in lofty houses, places for which many kinds are admirably adapted, or for training up pillars, where the tall-growing sorts are quite at home. As

SMALL PLANTS to flower well in 4½-inch and 6-inch pots, or at the most in one size larger, the fashionable B. insignis is still one of the very best. In the smaller pots this variety will flower in quite a dwarf state. In the larger the growth will be somewhat stronger, throwing out laterals which all flower profusely. Its colour, too, a pleasing, soft pink, is most attractive. B. Knowlseyana makes a more compact plant in the larger pots, being the more disposed of the two to branch out at the base. The flowers are larger and more of a pinkish-white in colour, but the trusses are generally smaller. This and B. insignis can be readily raised from seed, which should be saved earlier, and be sown in the spring or from cuttings in the spring. B. semperflorens and B. s. rosea (see cut) both make excellent plants for the winter, either cuttings or seedlings making good plants, too luxuriant growth being specially guarded against. Another capital kind is B. Digswelliana, of dwarf growth, with its flower-trusses produced very freely and well above the foliage. As a decorative plant, this is one of the best for the winter season. B. manicata is one of the best for flowering late in the winter or early in the spring, when it makes a capital plant for the conservatory. Cuttings every spring after flowering, or old ones kept on for large plants for two or three years, give the most serviceable stock. This, too, is a very useful kind for cutting to arrange in slender trumpet-shaped vases. B. Moonlight is of a pleasing colour, and makes a good addition to the winter collection. Under this name I am referring to one which was raised

by Col. Trevor Clarke and grown at Chiswick some years ago. B. prestoniensis is more of an autumn variety than a winter one. It is not much grown now, but some few years ago I well remember nice bushy plants of it being exhibited. Its flowers are of a bright-red colour, very distinct and sweetly scented. Those

BEAUTIFUL VARIETIES of the tuberous-rooted section, embracing the species B. ancotrana and the hybrids raised therefrom, as B. John Heal, B. Adonis, and B. Winter Gem, are all extremely useful, lasting so long in good condition. The duration of the individual flowers is also remarkable; in this latter respect they with-

A perpetual-flowering Begonia (B. semperflorens rosea).

stand the fogs well. Of this section B. Adonis is one of the most profuse-flowering and vigorous growers, whilst as a dwarf plant B. Winter Gem is simply what its name denotes. The culture of these Begonias does not receive that attention it should. As compared with the usual run of Tuberous Begonias, they require more warmth; this of itself is indicated by one of the parents—viz., the species B. ancotrana, which was introduced from Szechua in 1880. What may be termed a cool stove will suit this section of Begonias very well. I am quite of the opinion that it is only the question of a little time before these will be more extensively cultivated. The flower in the early spring note should be made of B. nitida odorata, also known under the name of B. suaveolens. This variety may be safely kept in a moderately warm greenhouse, when, of course, it flowers later. In warmth it can be included with the winter-flowering shrubby kinds. B. nitida itself will flower almost all the year round. I have seen it very fine in the summer, the winter, and spring. B. incarnata purpurea is more attractive, perhaps by reason of its dark, metallic-looking leaves; the flower-trusses, however, but a very long time in good condition. Besides these, there are other kinds which may be used for winter flowering; B. ascotensis, for instance, if bedded out in the summer will, if lifted early, flower well after being repotted. This variety, being a tall grower, is chiefly useful for standing amongst other and dwarf plants. There is also B. Princess Beatrice, a semi-tuberous variety, which can be had in flower in the winter season. G.

5171.—**Poinsettias**.—It is rather too soon yet to cut down Poinsettias. Give the plants six weeks' rest to get the wood firm and well ripened before cutting down; they will break all the stronger.—E. H.

5175.—**Gloxinias**.—These are by no means good window plants, for they thrive best in the moist, warm, and rather close atmosphere of a warm greenhouse or cool stove. In a dry atmosphere they are very liable to be attacked by thrips, and dust is also injurious by choking the pores of the leaves. The only way to do them at all in a window is to defer starting them until the warm weather commences, and keep them as long as possible, or until they become too large, standing on some moist Cocoa-nut fibre in a deep box, with a sheet of glass laid

over, or under ham-lights or cloches. About the end of April would be a good time to start the tubers, placing them singly in small pots of light rich sandy soil.—B. C. R.

—To do any good with Gloxinias in a window the bulbs must be rested during the winter in a dry condition and started into growth early in April; they will then flower during summer, when the natural heat is sufficient.—E. H.

5171.—**Treatment of Vallotas**.—I suppose the common Vallota purpurea or Scarborough Lily is referred to. The secret of getting this beautiful plant to bloom freely and well is to induce a strong growth during the early part of the season, and to ripen it off well in August, and then it seldom fails. The plants should be repotted in March or the early part of April, giving each a pot one or two sizes larger than before. Push them on in a greenhouse temperature, with plenty of water, and at the end of July stand the plants out in the full sun for a month, and give water rather sparingly. These plants do not, however, flower nearly as freely in a large town as in country places.—B. C. R.

—You do not ripen the growth. Encourage growth now, repot if necessary. Do not bury the bulbs much in the soil, and about the middle or end of June place the plants in a frame and ventilate freely even to the extent of full exposure in hot weather, and every strong bulb will flower.—E. H.

5191.—**A span-roofed greenhouse**.—You cannot grow Vines, Cucumbers, Tomatoes, and Strawberries altogether in one house, not to mention anything else. The cleverest man in the country could do no good with such a jumble. If you want to do the Vines justice—and remember that if a thing is worth doing at all it is worth doing well—you must not attempt to grow anything else in the same house (except during the winter, when they are at rest) but a few Ferns, Palms, or Fuchsias in pots. Some Strawberries in pots on a high shelf might be managed after the Vines were started, but even these want all the light and sun they can get, and will do but little good under the heavy shade of the Vine leaves.—B. C. R.

5185.—**Treatment of Tuberous**.—As soon as the bulbs have made roots in quantity plunge in a hot bed. It is best in forcing bulbs of all kinds to allow a little due to root formation before the hard work of forcing begins.—E. H.

5168.—**Lobelia for a basket**.—I do not know of a good blue-flowered Lobelia for a basket; but I may mention, in case you have not got it, that Miss Hope is one of the most delightful varieties of all for a basket. The flowers are not blue, but pure white, and are produced on slender, graceful, pendant shoots, which trail down over the basket. It is a veritable gem, and will worth growing in every greenhouse.—C. T.

—A good strain of speciosa is suitable.—E. H.
—Lobelia gracilis is decidedly the best for basket work, possessing as it does a long and gracefully drooping habit of growth. It is easily raised from seed, which should be sown in January or February, and may be had in separate colours, as blue, white, rose, &c.—H. C. R.

5123.—**Tuberous Begonias**.—Store the tubers in silver-sand in a dry, but not too warm place, where they will be safe from frost. The best time to pot them is early in the year, using a light, lumpy soil, and place them in a warm frame or greenhouse. Keep them syringed frequently, and do not let the soil be too wet. As the young shoots rise, shade very carefully from the sun, as, if too hot, the foliage will most assuredly get scorched. If in a frame, the plants may be removed to a greenhouse when the shoots are making headway, as a warm, stewing temperature is not required. Stake the stems carefully as they make headway to prevent them getting broken.—F. P.

—Let the Begonias remain as they are till February. By that time there will be signs of growth, and the tubers should then be repotted.—E. H.

5166.—**Creeper for a greenhouse**.—Nothing is better than Gloire de Dijon Rose. This can be pruned in fairly close, and flowers all the year round more or less. Lonicera sempervirens is good where Roses are not approved of. The orange and red blossoms of this latter climber are produced in quantity, and are most useful for furnishing flowers for vases.—S. P.

5130.—**A garden pit**.—Seeing that you want to grow Melons and Cucumbers in the pit during the summer, and have no fermenting materials, and with the probability that you would like to have these two subjects rather early, you cannot do better than heat the pit with hot water. A small boiler, fixed at one end, and a flow and return 3-inch pipe placed one over the other along against the front wall, with the top pipe up level with the wall plate, will give you sufficient warmth to keep out frost, and enable you to

start growing Cucumbers and Melons early in March. The front wall should be 18 inches or 2 feet above the ground level, and the back wall 1 foot higher than the front. To enable you to keep "Geraniums" in the pit during the winter a ventilator, 12 inches long and 6 inches deep, should be provided in both back and front walls in the centre of each light. For such a purpose as yours a span-roofed pit would be more convenient, with an interior width of 5 feet, and the walls 2 feet above ground all round, with the angle-ends filled up with glass. For such a pit a 3-inch hot-water pipe all round and with a small "independent" boiler fixed at one end, you will get ample warmth. In either case you should provide a movable trellis for the plants to stand on during the winter.—J. C. C.

5118. — **Begonia seed.**—This is the best of all ways of propagating the Tuberosus Begonia, whether the plants are for pots or the open ground. The practice of Mr. Laing, the well-known Begonia grower, is to sow about the third or fourth week in January; and those who have fire-heat at command are recommended to choose this time. Some sow in the summer months, but the seedlings then are apt to damp off. Sow the seeds in shallow pans filled with a soil made up of good leaf-mould, a portion of loam, and sharp silver-sand. Sprinkle over the surface some fine soil to make a good seed-bed, so to say; press it down firmly, and dip the pan in water carefully. Place the pan or pans on a good bottom-heat, and when the seedlings are of sufficient size prick them off into other pans or boxes. They will need transferring two or three times, as the seed, if good, comes up freely. A small, finely-pointed stick of wood will do well for pricking them out with. Early in May commence to harden them off, as they must not be in the least tender when put out in the open. Previously, however, the position in which they are to be planted must be well manured, and dig it up at once, so as to get it thoroughly pulverised and sweetened by frost. This year tuberosus Begonias were not a success—at least, until very late—owing to the unusual dryness of the weather.—C. T.

Watering Palms.—These princes of the vegetable kingdom often suffer from one of two causes. If it be not that of sufficient warmth, it will possibly be that of insufficient moisture at the roots. When the plants are well rooted, as they should be at this season, they will still take a liberal supply of water. To allow them to become dry at the roots is simply a slow process either of killing them or of rendering them so unsightly as to be of but little use. It is in the store where the plants will dry up the quickest, and if so be they are very much pot-bound, they must be looked after daily, seeing at the same time that they are thoroughly soaked. Once watering them is not in many cases sufficient for this purpose, for it may happen that the roots have forced up the soil, so that no average amount of water can be given at any one time. Palms, unlike Tree-Ferns, do not at once show the results of an oversight in watering, but it will appear in due course all the same. There need not be any fear of injury by keeping them watered liberally so long as they are healthy at the roots. Although in most cases any stimulating agent in the form of natural or artificial manures is not advisable whilst but little growth is being made, in the case of Palms it will be found an exception to the rule. These plants require it to sustain them in health and vigour, more particularly when they have drawn out the chief virtues of the soil. For this purpose I have used "Stanley's Manure," a compound of a highly concentrated character. A dusting of this over the surface of the soil about once a week will greatly assist them, a pinch between the thumb and two fingers being enough for the largest plants at one time, others that are smaller being treated in proportion. When this is applied the next watering should be done steadily through a pot with a fine rose upon it. Greenhouse Palms may be treated in a similar fashion, but these will not take quite so much water; nevertheless, do not let them suffer. Where plants for special reasons are retained in extremely small pots, then I would prefer to stand them in pans as a safeguard against drought. Those who may have in their collection plants of *Stenandrium graminifolium*, *Vesuviana splendens*, or any other tropical Palms should

look to it that they do not suffer by a low temperature; for these, 60 degs. at night should be the very lowest.—J.

HOUSE & WINDOW GARDENING.

LEAVES FOR TABLE DECORATION.

DURING the past autumn months I have found coloured leaves most valuable for dinner-table decoration. A few of the best I used were those of *Rosa rugosa*, which were of a very rich yellow hue. On some bushes in a shady situation they were far better than in the sun. The leaves, again, from a Maple I have in the pleasure grounds died off a particular shade of crimson and yellow, and the Silver Maples are also valuable for room decoration. *Ampelopsis Veitchii* has been used with good effect. I had the leaves of some plants of this are far brighter than those of others, although growing side by side. The foliage of *Ampelopsis Hoggii* dies off bright yellow, and may be worth planting beside *A. Veitchii* for contrast. Strawberry-leaves I used

Leaves of a Silver Maple.

with very good results; Keen's Seedling leaves generally turn to a beautiful crimson and yellow, with black spots on them. These I placed two or three together with a single bloom of a *Chrysanthemum* of the same shade of colour in the centre. J.

A FEW USEFUL WINDOW PLANTS.

Most lovers of flowers must have been struck with the superior manner in which plants thrive with one person to what they do with another. There are few sights more pleasing than a cottage window well filled with flowers, and as success depends to a great extent upon a judicious selection, this note may be welcome to some readers of *GARDENING*. Profoundly the most generally useful window plants are the Zonal Pelargoniums, or "Geraniums," as they are more commonly called. These have been immensely improved of late years, and it is possible now to have a great variety of colour with equal freedom in blooming to that possessed by the old *Vesuvius*. Very grand trusses of large blooms are easily secured. The varieties are far too numerous for me to name. All they need is good soil, careful watering, and occasional pinching out of the points. The strongest roots. The Hedgehog Cactus (*Echinopsi-*

cyrosi) and others of the same family will bloom freely. I have also noticed *Epiphyllum truncatum* enlivening a window all through early spring. The grand *Duindo Petunias* which used to be grown by cottagers are by no means so frequently met with as formerly; but there is no reason for this, as they are still among the most suitable. I have heard them objected to on account of being so subject to green-fly, but I do not believe they are a bit more so than in former years. All plants have their enemies, but the window gardener of to-day does not pay sufficient attention to the early application of remedies. With the *Petunia* it will be best to brush the insects off as much as possible, and then syringe with clean water. A great deal towards cleanliness might be accomplished by removing insect pests in this manner. The Giant and Common Musk, the Monkey-flower, Campanulas, Fuchsias, *Frimula oleacea*, Arum Lilies (especially the dwarf type now introduced), various bulbs, the Scarborough Lily, *Polyanthuses*, *Pansies*, and many more cheap and easily procured subjects are well adapted for window culture. Among foliage plants we have the Milk or Parlour Palm (*Aspidistra lurida*), the India-rubber-plant (*Ficus elastica*), a large variety of hardy and half-hardy Ferns, &c., which space will not allow of enumerating. The chief points are to select plants of simple cultural requirements, avoiding all which need a warm greenhouse or stove temperature. A most important element towards success is careful and thoughtful watering. At the present time, too, much depends upon the plant being removed from the window at night. When the blinds are drawn, either lift the plants out and stand on the floor or else place a newspaper between them and the glass. Which of these plans is to be adopted must depend upon the weather and also upon the subject you are growing. Give the plants as much light as possible, and syringe them oftener than is generally the practice. A wash freshens them up to a wonderful extent, and keeping the pores open is a greater element towards success than is realised by many would-be cultivators. I would also earnestly warn against the extreme change plants often have to bear when windows are opened upon a brisk, drying day. It is this sudden change in temperature and atmospheric conditions which often affords them an injurious check.

P. U.

Calla aethiopica (Arum Lily) for a room.

—There are few more stately plants than a well-grown *Calla*, and as they do very well in a room-window (without gas) they should more often be seen as a drawing-room decoration than they are. Coming into bloom in December, just when other flowers are falling, they are specially valuable too, and each bloom lasts ten days or more at this time of year in full beauty. Plants that have been well-tended throughout the summer are now very strong, throwing up thick spathe of handsome shining leaves and ivory buds, and these will now need plenty of water. The *Calla* is, in fact, a semi-aquatic plant, and must never become too dry, while at this time of year when it is in full growth it should stand in a saucer of water, or, still better, not-water, in a thin clear state, as it is a hungry feeder. Any neglect in supplying water will result in a bad attack of green-fly, while well-fed plants seldom suffer in this way. The plants may be much helped by a mulch of rich soil around their stems, for they form their large leaves and flowers so rapidly that the soil often sinks an inch or two from the top of the pot after they have started in September, and this should be filled up with more good soil when necessary. A bit of soft sponge and a little luke-warm water should be constantly used to keep them perfectly clean, as their beauty depends so greatly upon the purity of their freely-expanded flowers, and the slightest symptom of green-fly (which often attacks the

smaller foliage near the base before reaching the flower) should be removed with soap and water without loss of time. The plants should be constantly turned round, so as to expose each side equally to the light, and will then grow into very handsome specimens. After flowering—i.e., at the end of May—they are best placed in a half-shady position out-of-doors, and supplied (if kept in their pots) with a mulch of good soil, and plenty of water through the summer. They can, however, be planted in good garden soil, when they give less trouble to keep them watered, in either case being divided and repotted in rich stuff in September.

I. L. R.

1143.—**Cytisus plants in a drawing-room.**—"Daphne" does not say whether gas is burned in the drawing-room in which these plants are placed; if so, that would account for the leaves and buds dropping off. Gas not only dries the air extremely, but gives out highly deleterious gases, which destroy flowers at once, and injure most plants. Those who burn gas must content themselves with foliage plants, such as some of the Palms, the India-rubber-plant, and one or two of the Dracaenas, with a few Ficus Ferns, but even these will not look happy if kept long in the fumes of gas. Another possible cause of the flower-buds failing is the cold sharp draught caused by opening windows and doors in the early morning to brush out the room. Plants are best removed into the greenhouse at night, or, if this is not feasible, they should be covered with a newspaper on a side table, to protect them a little from the dust, as well as the icy blasts in the morning. A better plan is to remove them into a bed-room, or a bathroom in which there are hot-water pipes always warm, turning on the hot-water for a few minutes to moisten the air, and they should be allowed to stand here until after breakfast on the following day, being replaced in the bathroom before the gas is lighted. This is an excellent arrangement for Ferns and foliage plants; but where flower-buds are on the point of opening they must have sunshine, or they will fail from that cause. If they can be lifted into a sunny window in the morning they will be much assisted, and they should be placed as near the glass as possible. *Cytisus* plants, and, indeed, all plants in bloom, require plenty of water, and this should be given tepid, whenever the surface-soil in the pots is dry. Never water a wet plant, however, especially if it be a *Primula*, as these damp off easily, just at the point where they emerge from the soil, especially if they have been chilled beforehand. A stand or table, covered by a zinc tray full of fresh Moss (which should always be kept damp), is a good place for room plants if standing in a sunny window; the slight moisture always rising from the Moss prevents the bad effects of dry fire-heat, and helps to nourish the flowers and foliage.—I. L. R.

5187.—**Arum Lilies.**—The window is too cold for the Arum Lily at this time of year, as even in a room in which there is a fire pretty constantly the flower-scape does not unfold satisfactorily. The whole secret of the trouble is that you have not heat enough. This Lily requires a steady temperature of 60 degs. in winter to get the flowers to open properly. The summer treatment is right enough, but another year you may try planting them out earlier or about the end of May. You may then find them showing flower in the autumn before the weather gets very cold.—J. C. C.

—The temperature is too low. Arum Lilies want heat to open their flowers in winter. Should suppose the roots are healthy and sufficiently numerous.—E. H.

—It is simply more heat that is required. At this season the flowers will not expand kindly in a lower temperature than 60 degs. to 70 degs., with plenty of moisture both at the root and in the atmosphere. In a stove or forcing-house they would soon open.—B. C. R.

Saving seeds.—Many people, especially amateurs, save their own seeds, and they wonder why the produce from such seeds deteriorates. The reason is simple enough, as there is no attention given to the selecting of them during the stages of their growth. For example, Peas are picked till only the poorest pods are left. The poorest roots of some vegetables are often saved for seed. Potatoes often are so treated, and that is the reason why the progeny is frequently so poor. Some time ago I

saw a member of a large seed firm selecting his stock of Turnips; he travelled through the immense localities of hulbs, examining carefully those which were to supply the seed which has kept up for long the fame of their establishment.—K.

OUTDOOR PLANTS.

THE PINK.

THIS is one of the sweetest of hardy garden flowers and more easily managed than its near ally, the Carnation. Near where I write Pinks are grown by the acre to produce cut flowers for the markets in the East-end of London. A variety with white fringed flowers is the most popular. The flowers are not more than semi-double if compared with the large full blooms of the show Pinks, but they are produced in great profusion. The plants would grow larger and better flowers if more care was taken with their culture; but the object is to make a profit out of the cut flowers, and this cannot be done, it seems, unless the plants are merely laid in as the ground is ploughed. And this passes for planting, and the farmers are satisfied if they can obtain 1s. 6d. for a dozen bunches. Each bunch is a good handful. I have grown this same fringed white variety in my own garden, and like it better than the varieties with full flowers, which burst the calyx and are quite useless for cutting. The coloured border Pinks are very pretty, and may either be grown as hardy border plants or be specially prepared for forcing. The fringed white is a good one, and

LADY BLANCHE, which I cultivated for twenty years, is the prettiest of the white varieties, but it seems to have much declined in vigour. I do not like the over-full flowers of such a variety as Mrs. Stukins. Lord Lyons, is, I think, the best of the rosy or pink-coloured varieties with dark centres, the older variety of this type, Anne Bolayn, having larger and less pretty flowers. Derby Day is distinct from the above, these three being good type flowers. It is not well to force them an early in a very high temperature, but with care and a little gentle forcing they flower profusely in April and May. April is a good month in which to strike the cuttings. The small side growths strike more readily than Carnation cuttings in a forcing-house or hot-bed, and they must be planted out in boxes soon after roots have formed, and be grown on in frames to be planted out about 1 foot asunder in May or early in June. Keep the hoe at work amongst them in summer, and water when dry, but weather sets in. About the last week in September or early in October the plants may be taken up and placed in 6-inch or 7-inch flower-pots, according to their size. They may be placed close together in cold frames ready to be transferred to a gentle heat at intervals from Christmas. A few plants should be put in every two weeks. It is not necessary to have special forcing-houses for Pinks; they can be placed in an earlyinery or Peach-house when started, and as the flowers begin to expand, place the plants in the greenhouse, where the flowers will open well and remain longer in good condition. Green-fly may attack them, but in other respects they are easily grown, and the aphid tribe may be destroyed by dipping or fuming. The plants may not all be wanted to force, but they winter well out-of-doors if planted in October. The

SNOW PINK is not adapted for forcing, not that the plants are not amenable to culture under this treatment, but their individuality consists in what the fanciers term *lacing*—that is, the marginal colour, which disappears wholly or in part if the plants are forced; moreover, it will be found that if the plants are kept in boxes and planted out in the spring the lacing is almost sure to be imperfect. The details of the management of lacee or show Pinks may be summarised as follows: It is a good thing to get the pipings in early, say as soon as they can be obtained after the middle of June. I used to propagate Pinks very well at a time when I neither had frames, hand-lights, nor glass structures of any kind. My plan was to prepare a piece of ground in a shady place by mixing with the soil coarse sand and well-decayed leaf-mould. Get the pipings off on a wet day, and when the ground is wet. I do not use a stick to

put them in, but simply press each piping into the ground with the first finger of the right hand. They will form roots out-of-doors, and if wet weather sets in for a time scarcely one will fail. If the weather is dry and sunny, they must be shaded, and sprinkled with water once or twice a day. They strike more readily, of course, if planted in boxes and pined in a gentle hot-bed. When the pipings have formed roots and have grown a little, they must be planted out in a favourable place out-of-doors about 4 inches asunder, to be planted again about the end of September in an open position and in good soil. The soil should be well prepared previously, and be in good condition at planting-time. If it should happen to be very wet and the rain continues, it is a good plan to dig out the soil where the plant is to be placed with a trowel, replacing the wet material with some nice dry compost from the potting-shed. This gives the plants a good start, and a chance to become well established.

GOOD STRONG PLANTS may be set out about a foot asunder. The Pink has a more slender, wiry stem than the Carnation, and is not quite so readily destroyed by wireworms; but this pest will attack and kill many if it is in the soil. The leather-coated grub buries itself in the ground by day, and, venturing out at night, it eats the leaves voraciously, retiring underground when satisfied. It can generally be detected feeding at night with a light, or if the ground is scratched to the depth of an inch or two it may be found, or by the pieces of Pink leaves they have tried to drag under ground. Slugs are also troublesome. Alternate frosts and thaws also throw the plants out of the ground, and it is necessary during winter to look over them several times and make the plants firm by pressing them in with the fingers. They seldom suffer from the effects of climate in Britain north or south, but it is well to raise the ground where the plants are above the surrounding level in wet districts. J.

5176.—**Gladiolus The Bride.**—It is quite possible that this *Gladiolus* is sufficiently hardy to pass through a severe winter unharmed on the south coast, but here, in Somersetshire, it cannot be depended upon to do so, only in very sheltered positions. The cornus do not get injured if planted in the autumn, but as they begin to grow directly they are planted the frost injures the leaves, and, as a consequence, they bloom very sparsely, and sometimes not at all. I have put the bulbs in pots in the autumn, and keep them in a cold frame, and plant them out about the middle of April.—J. C. C.

—You may plant hulbs of this in the autumn for early summer flowering, and unless the position is very cold, or badly drained, the bulbs may be left in the ground throughout the winter, with a covering of coal ashes or similar protection. But this type of bulb is best grown in pots, and is very suitable for gently forcing into flower. At any rate, as regards the open, if the position is warm, the soil light and well drained, and the bulbs protected if thought necessary, they may remain in the ground through the winter months.—F.

—The race of *Gladiolus* from which *The Bride* is derived is hardy enough to stand the winter outside in warm soils, and may, of course, be planted in autumn, being an early blooming kind, that is the natural season for it; but in unfavourable situations it would be safer to pot the bulbs and keep in a sheltered place, plunged in a cold pit, for instance, and plant out in March.—E. H.

5177.—**Michaelmas Daisies.**—The two best dwarf varieties are *Aster acris* and *A. anellus*. The former grows about 2 feet in height, and early in the autumn smothered with lilac flowers. It is a vigorous and handsome variety, not grown half so much as it deserves in gardens. Mixed with *Chrysanthemum Mme. Desgrange*, and a charming effect is got. *A. anellus* has rich purple-blue flowers in profusion, large individually, and creating a wealth of beautiful colour. This grows about 2 feet in height, a little taller than mentioned by you; but such varieties as these must not be excluded. *A. alpinus* is one of the first to bloom, and is a beautiful mountain flower, appropriately called the *Blue Mountain Daisy*. The flowers are large, and there is a white form. It does not grow a foot in height, and is not troublesome to bloom well. *Hybridus nanus*, grows about 18 inches in height, the growth neat, and forms quite a little bush, smothered with pink

and white flowers. A very fine kind is longifolius formosus, the plant growing 2 feet in height, and the flowers of a rose colour in profusion. It is a very useful kind, and you may also select discolor, which attains a good height, the flowers white, passing to a pinkish colour. These dwarf kinds are very fine when massed together, especially *A. amellus*. I may mention that there is a variety called in catalogues *amellus besselianus*, but there is no difference between this and the type.—C. T.

The six very best dwarf kinds are *Aster amellus*, the form known as *besselianus*, *Aster crispus* and *lewisii*, *A. longifolius formosus*, *A. persicolor* (dwarf form), and *A. reniformis* var. *Clara*. These can be obtained true to name from Mr. Barr, of King-street, Covent-garden.—A. H.

5189.—**A steep border.**—The edging of red sandstone gives a good opportunity for growing many pretty things on the margin of the border, and among them the good old *Aralis nuda*, *Yellow Alyssum*, *Anthriscus* in variety, *Thymus serpyllum* and *laingianus*, *Saxifraga hypnoides*, *Phloxes*, such as *amarna* and *subulata* and its varieties, and above all *Campanula pumila* in blue and white forms a thing of beauty the whole summer through.—A. H.

There are plenty of plants suitable for planting in the stone bordering of the border. Tufts of the Mossy Saxifrage and several other forms of Saxifrage, including the London Pride (*S. umbrosa*), which grows and flowers so well in the smoke, *Sedum Sieboldii*, *Honeysuckle* in variety, including the Cobweb *Honeysuckle*. Among early-flowering plants, *Anthriscus* and *Arabis alba* are very pretty. Something might be done with common hardy lilies that would grow through the foliage of other plants, the variegated *Ivies*, for instance.—E. H.

There are hosts of things suitable for such a position—among stones on the edge of a bank of soil, *Anthriscus* in variety, the White *Arabis*, *Alyssum saxatile*, *London Pride*, and a number of other Saxifrage, *Sedum*, *Thillis*, &c., will all do well here.—B. C. H.

Achillea millefolium rosea.—This is also called the Rosy Yarrow. It is a beautiful member of an interesting family, the flowers almost crimson, large, and showy. It will live in almost any soil, grows freely, and has a bushy habit, the height 2 feet. *A. ptarmica* fl. pl. is another vigorous species, a most useful border plant, bearing a profusion of double white flowers that are acceptable when cut for decorations. Its proper name is the Double Sneezewort, and it will grow in ordinary soil.—F. P.

Polygonums (Knotweeds).—These are troublesome but beautiful perennials—troublesome for the reason that once established in a garden it requires patience to prevent the plant running into every nook and corner, and making many fair favourites from their rightful position. The most familiar species is *P. cuscutatum*, a native of Japan, and the tender shoots that grow up through the ground are considered a delicacy by the Japanese, hence the name Japanese Asparagus sometimes given to them. It will grow in any soil and any position, but to derive full pleasure from its graceful stems, smothered in summer with clusters of white flowers, it must not be too much shaded. Isolated by itself in clumps, or planted by the waterside, as in St. James's park, the nut-brown stems standing out clearly in the winter months, it has a distinct and fascinating beauty. A variety of it named *compactum* is dwarfier, and the leaves more wrinkled than in the parent form.—F. P.

Plantain Lilies (*Funkias*).—These are delightful Japanese plants, allied to the Lily, and of value for the broad, healthy leafage, in some species accompanied by flowers of great beauty. The most suitable for our purpose is *F. ovata*, which has wide, deeply-coloured leaves, remarkably handsome by reason not only of their rich abundance, but shining, pleasant colour. A very favourite way of growing it is in a tub, and here, even in the dark alley, absolutely fatal to flowers in general, it will increase year by year, growing in beauty as it advances in age. The flowers are individually small, but in the aggregate have a charming beauty, the lilac enduring being at once distinct and pretty. This *Funkia* will endure hardship, and if variety is desired, there is a variegated-leaved form, just as hardy and vigorous as the parent. If increase of stock is required, it is very easy to divide the roots by careful separation.—F. P.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be omitted, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, ants, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

5211.—**Roof for a wire arch.**—Is the Rose W. A. Richardson suitable for a wire arch?—A. O. M.

5212.—**Whitlavia grandiflora.**—I should like to know if *Whitlavia grandiflora* will make a nice pot-plant?—Puzzled.

5213.—**Andromeda floribunda.**—I would like to know how *Andromeda floribunda* is best propagated?—Miss Brown, Hendon.

5214.—**Humea elegans.**—I have some *Humea elegans* seedlings, about 1 inch high, in a pan now. How shall I treat them?—CONSTANT READER.

5215.—**Tea Roses.**—Will someone kindly tell me the names of six good Tea Roses that will thrive well near the sea, and best time of planting?—ANNON.

5216.—**Grafting a Holly.**—I wish to know if a Variegated Holly can be grafted on to a Green one? At what season should it be grafted?—Miss Brown, Hendon.

5217.—**Rose Charles Lefebvre.**—Will someone kindly tell me if the H.P. Rose Charles Lefebvre is one which can be depended upon for free blooming, also if it is hardy?—ANNON.

5218.—**Gladiol for show.**—Will someone kindly tell me the most effective way of showing *Gladiolus*-spikes, say, for about 45 varieties? I want to make a stand at my garden.—GAMMEL.

5219.—**Yew from cuttings.**—I should feel much obliged if someone would kindly tell me the common Yew could be grown well from cuttings?—ATULONX, Co. Kildare, Ireland.

5220.—**Plants in a small garden.**—I should be glad to know if the Japanese Maple, Chinese Garden Rose, and *Spiraea Thunbergia* are suited for a small garden?—A. G. M.

5221.—**Dateles, &c., on a lawn.**—Will someone kindly tell me how to free a small lawn from Dateles and other weeds? Are any of the weed-killers sold for the purpose useful?—J. F. G.

5222.—**Pears and Plums.**—Will someone kindly oblige me with the names of the best six Pears and Plums (classes) for succession, and also a good baking Pear?—CONSTANT READER, St. Neots.

5223.—**Planting a branch of a Mulberry tree.**—I have a branch of a Mulberry tree blown down. Is it of any use to plant it? Will cuttings of it grow, and when and how should they be planted?—Miss Grant, Highgate.

5224.—**Allanthurus glandulosa, &c.**—I have purchased plants of *Allanthurus glandulosa* and *Allanthurus manschuricus*. Will someone kindly tell me when the stems should be cut over, as it is recommended to do so annually?—W. H.

5225.—**Destroying mealy-bug.**—Will someone kindly tell me the best way to get rid of mealy-bug on a *Taxodium*? What would be the best dressing to use? Would it be advisable to cut the plant back and let it start afresh?—J. H.

5226.—**Tea Roses in pots.**—I should be pleased if someone would kindly name twelve dwarf Tea Roses, (see flowers), to grow in pots in a cold greenhouse, district, 8 miles north of Manchester? Would it be best to buy them in pots or otherwise?—H. S.

5227.—**Propagating Chrysanthemum.**—How are these varieties to be propagated which do not send up suckers? For instance, I have a plant of *Edith Molyneux*, which has just gone out of bloom and has no uprising shoot from the place nor sign of one.—T. D. L.

5228.—**Cutting back Hydrangea.**—It is sometimes recommended, I believe, to cut back plants of *Hydrangea*. I have bought some specimens of *H. paniculata grandiflora*. When should they be cut over, and how near to the ground? Should it, hortense be treated in the same way?—W. R.

5229.—**Hot-bed.**—Having lately taken to use Peat-Moss-litter in the stable instead of straw, please inform me how I can make a hot-bed for a frame? My gardeners say it cannot be done without straw. I have plenty of loam. Would these, mixed with the Moss-fitter from the stable, generate heat?—W. R. H.

5230.—**An old neglected garden.**—Advice wanted for heavy clay soil. What vegetables, flowers, and shrubs are best planted in an old neglected garden with large trees surrounding it? A gardener kept. I want especially advice on planting shrubs under shady trees, and all up gaps?—STONHAM.

5231.—**Anemone roots and worms.**—I and my quantity of small white worms are attacking my

Anemone roots. Could anyone kindly say what they are and suggest a remedy? I would wish to try salt, but am ignorant of the quantity required per yard, and would be grateful for information on the subject?—ATULONX, Co. Kildare, Ireland.

5232.—**Gold fish.**—Will anyone kindly tell me what is the best food for these fish in a conservatory? My basin holds about 10 gallons of water, and the fountain is constantly running to keep the water fresh. I have a variety of fish some worms cut up and coarse animal matter but four have died and are misshapen by swelling in the middle.—N. Y. Z.

5233.—**Herbaceous Calceolarias, &c.**—I have a number of herbaceous Calceolarias in 1-inch pots, and all the hours have turned a variegated colour; and I have also some plants of *Phloxia chinensis* the same, the leaves go white and then die. What is the cause? I have some Chinese Primulas and *Cimicifuga* doing well in the same kind of soil.—Pizzako.

5234.—**Carnation Souvenir de la Malmalson.**—I had a lot of *Souvenir de la Malmalson* Carnations last summer, but most of the blooms were affected with a kind of damp on the outer petals. I cannot account for it, as my house is an airy one, and I am sure I did not keep the plants too wet at the roots. I fed them with some patent-manure. I wonder if that would cause it?—Bourton.

5235.—**Tuberose Begonias.**—I have just procured one dozen Double Tuberose Begonias. The names of them are: *Althildora*, *Sultan*, *Marquis* of *Stafford*, *Mons. E. Fongol*, *Lorna Doone*, *Diamond*, *Mons. Oberia*, *Maurette*, *Virginalis*, *Toison d'Or*, *Mme. Arroul*, *Mme. Comesse*. I should like to know if the above are good varieties, and the colour of the flowers? Should I pot them now, or wait until spring?—HONATA.

5236.—**Propagating-pit.**—I have a brick pit in my cold greenhouse, 2 feet 9 inches by 2 feet 6 inches. There is a frame with light over it. I wish to turn this into a propagator. I should be very much obliged to B. C. H., C. T. Y. or any other person, if they will give me instructions how to fit it up with oil-lamp, hot-water pan, and all fittings to make it work successfully. I wish to strike cuttings and to raise seeds in it in the spring.—PROFANATOR.

5237.—**A span-roofed greenhouse.**—I have a span-roofed greenhouse, about 7 yards long, 16 feet wide, and about 8 feet or 9 feet high. Will anyone kindly furnish me with a list of Chrysanthemums, of varied colours and kinds, that would make a good display next winter? How many plants should I grow in the house? Perhaps someone would be good enough to state the colours and the class to which each belongs. Of course, I do not purpose going in for the very high-priced ones.—C. M.

5238.—**Cutting down greenhouse plants.**—In my greenhouse I have a number of plants which need cutting down, including *Fuchsia*, *Geraniums*, *Begonias*, *Heliotropium*, *Abutilum*, &c. When is the best time to do this so that I may be able to strike a lot of cuttings from the plants? I have about a 15-gallon water-trough round a globe, which I wish to chain round a tree. Will it be used up during the winter, and when and how? What kind of soil will it require, and should it be repotted every year?—C. M.

5239.—**Hoya carnea.**—In a greenhouse I have recently purchased there is a *Hoya carnea*, probably four or five years old. It is planted in an inconvenient place, and I am thinking of moving it and planting it in a box over two 4-inch leading pipes and training it along the roof. Is this treatment advisable, and if I note it during the next two or three weeks is it likely to bloom well in the spring or summer? What kind of soil should it be planted in, and what kind of drainage is necessary? Should it be put down, and how? Some of the shoots may be 5 feet to 10 feet long.—C. M.

5240.—**Propagating Chrysanthemum.**—Will "K. M." or someone else kindly state what is the best course to take when suckers do not grow up from the base of the plants so that they may raise fresh plants for another year? I have about 15 cuttings struck, with the exception of those from which I am unable to procure any. I have cut down the plants to within 4 inches of the base, and put new soil on the top; but none appear to grow as yet at present. Will it be of any use taking some of the side slips to propagate from, or will it be waste of time, as I have been informed they make plants but they do not flower?—ANNON'S ENQUIRER.

5241.—**"Bush" Chrysanthemum.**—Will "E. M." kindly give me the names of six coloured and three white Chrysanthemums for growing on the bush system, but only allowing the crown-bud on each branch to bloom? I want them to be Japanese. I have the following: *Source d'Or*, *Mons. Bernard*, *Enter the Great*, *roseum spectabile*, *Madison's Bush*, *William Robinson*, *Val d'Adore*, and *Botanica*, *Fair*. These last two are done very well with me in 7-inch pots, so I should be glad if "E. M." would say which four would do in the same sized pots? I should like as much variety of colour as possible, and not too tall-growing sorts, and all to bloom about the same time.—H. H. WALKER.

5242.—**Lily of the Valley.**—I have four pots of German plumps of these, which I have plunged in Cocoanut-fibre in a little frame in a store; there are hot-water pipes underneath the frame for bottom-heat. I maintain a temperature in the house of from 55 degs. to 60 degs. at night, with a rise of 4 degs. to 10 degs. in the day. I covered the tops of the crowns with Moss, which I kept a moist by using water from a syringe. After the Lilies had made about 2 inches of growth I covered the Moss, and placed an empty flower-pot over the crowns for about a week, which brought the flower-spikes up; but I can see no signs of there being any leaves. How is this, and how should I proceed in future, as I have six more pots to force?—Lily.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of new plants or flowers and good fruits and vegetables for drawing. The drawings made will be engraved in the best manner and will appear in due course in *GARDENING*. (Illustrated.)

NEW PHOTOGRAPHIC COMPETITION FOR 1893.

LIST OF AWARDS.

Class I.—FLOWERING PLANTS: The Prize is awarded to Mr. S. W. Fitcherbert, Lansdowne House, Cockington, Torquay, for a series of excellent photographs of many beautiful garden scenes.

Class II.—BEST GARDEN FRUITS: No sufficiently good photographs were sent in to justify awarding the Prize offered. In the extra Prize List below will be found some photographs that have been chosen.

Class III.—BEST VEGETABLES: The Prize is awarded to Mr. Norman Blake, Belford. This is the best collection of photographs of vegetables that has been sent in for any of our Competitions.

Class IV.—AUTUMN FLOWERS AND LEAVES: The Prize is awarded to Mrs. Martin, Bournebrook Hall, Birmingham, for photographs of prettily arranged autumn flowers and leaves.

EXTRA PRIZES.

Miss Armstrong, 5, Clifton-terrace, Monkstown, Dublin. Silver epergne arranged with White Nicotiana; a hanging basket of Passion-flowers and fruit; and a basket of Double Geraniums and Heliotrope.

Lady Eleanor Stopford, Courtown, Gorey, Ireland. Belladonna Lilies; African Tuberoses; and Potato "Imperator."

Mr. F. M. Ramell, 34, High-street, West-end, Sittingbourne. Hociety in a vase; and a bouquet of Water Lilies and Grasses.

The Countess of Antrim, Glencarrig Castle, Co. Antrim, Ireland. Arch of Escallonia; and border of Poppies.

Mrs. Marion Porter, Bloomfield Lake, Sandown, I. of Wight. Grape "Blackland Sweet-water," and Apple "Emperor Alexander."

Miss Alice Worsley, Rolney Lodge, Clifton, Bristol. Pear "Easter Beurré," and Pear "Beurré d'Arenberg."

Miss Ethel Fitz-Roy, Forest Farm, Balcombe, Haywards-leath, Sussex. A Lily Garden; and Nymphaea deudanta.

Mr. E. B. Barrowes, Moreton House, Buckingham. White Sweet Sultan; and White Moccasin-flower.

Mr. H. Keens, 24, Herbert-road, Lewisham. A Giant Gourd; and Grountop Stone Turnip.

Mr. I. Goody, Belchamp, St. Paul, Clere, Suffolk. A Musk Melon; and Japanese Cucumber.

Miss Rawson, Millhouse, Halifax. A basket of Peas.

Mr. Cecil Shaw, 14, College-square, E. Belfast, Ireland. Chrysanthemum "Victim Murel."

Mr. T. Wight, Trysall Green, Seisdon, Wolverhampton. Cottage-porch, covered with creepers.

Mr. George Capes, Yew Bank, Caistor, Lincolnshire. Border of Chrysanthemum Minor, Desgrange.

Mr. Leonard M. Powell, Bayford Grange, Hertford. Group of Asters and Pyrethrum uliginosum.

Miss Mabel Gaisford, The Grove, Dunboyne, Ireland. Vegetable Marrow "Large White."

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—Mrs. Cameron.—The Sedum is Sedum Ewersi; other plant with spotted leaf is Farligium grande.—J. T.—Fern Pteris argyrea.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

ROSES.

FORCING ROSES.

It is not often that we meet with Roses that are being forced for early blooms growing in the same healthy and pleasing manner as plants that are not started until February. And yet there is little reason for this, provided one commences with properly matured plants and continues to treat them on the right lines. Perhaps there are few plants more disappointing than early forced Roses when fully grown. Partially ripened plants soon push into new growth, but it is almost always of a weak and puny character. Needless to say, it is impossible for such to produce blooms of satisfactory quality. To secure good Roses under the strain of early forcing, it is absolutely necessary to commence with well-matured wood and established plants. When either of these essentials is wanting the results are certain to be disappointing. There is a further essential in forcing Roses successfully; that is, to start them gradually and with as little unnatural excitement as possible. If started in too hasty a manner, the sap in the wood is excited and put into premature activity. This should not be until the roots are able to produce a further supply. If you exhaust the sap in the wood by the production of a new leaf-growth, you must expect a check of greater or less severity according to the state of the roots.

Too much impatience in starting Roses and too high a temperature in the earlier stages are the chief causes of so many partial failures. Nor should one attempt to force weakly plants, as unless they have a good constitution it is hardly possible for them to produce blooms of any merit, especially when under the strain of early forcing. There is also a great deal in making a judicious selection of varieties, always choosing those that are naturally free-flowering. It is also wisest to select kinds that are not too double, as they will expand more freely, and are much less liable to damp in the centre or to produce what are styled gummy buds. Many Roses that are practically useless during the summer, owing to their flying open so rapidly and possessing few petals, make the finest of all Roses for winter blooming. During this time they will not expand too freely, and will retain a close and pleasing shape for a long time. Of all flowers perhaps Roses in winter are the most appreciated, and with a little care and consideration it is by no means difficult to have them. I will not give a selection of suitable varieties, as they are now very numerous; suffice it to say that all free bloomers, of not too double and globular character, are well adapted for early or winter forcing. I have known many batches of good pot-Roses spoil for early forcing by being pruned and then stood in the forcing house at once. A very little thought will show the folly and unadvisedness of this. Summer does not burst upon us in a day. And yet that is practically what such treatment amounts to. All Roses intended for early forcing should be

pruned without delay if not already done. By stamling them in a close pit for a month or six weeks previous to removing them to the forcing house, you get the eyes plump and forward, and the sap about equally in action with the roots. A very little

ARTIFICIAL HEAT is needed during the first month of forcing, letting the temperature increase gradually, and never exceeding 65 degs. to 70 degs. The latter is quite high enough for Roses under the most highly forced conditions. Great care and attention will be necessary in the application of water, and perfect cleanliness must be secured. Drought at the roots, a few insects, or a slight attack of mildew make great havoc among early forced Roses. As the plants retain a fair amount of leafage, liquid-manure is very beneficial and in many cases almost a necessity. Much better results will be secured if Roses are not forced until the days are well turned. Those possessing only a few ornamental greenhouses that are doing duty for numerous greenhouses I would not advise to force Roses at all. Their best plan would be to wait until they come on in a more natural manner, simply affording them the heat and protection accorded to ordinary greenhouse plants.

R.

5211.—*Rose* for a wire arch.—"A. O. M." may safely plant William Alba Richardson upon an arch. It is a strong grower, as a rule, but a plant will sometimes linger about one size for two or three years. When such is the case plant another specimen. I mention this freak of W. A. Richardson because more than one has desecrated it as a climber simply because their own specimen did not happen to do well. For the past five years I have tried to account for this peculiarity, but without the least result so far. Neither soil or stock seem the cause; if they are, it has baffled me to decide in what way. I have left a plant unstarved and placed another by its side, and although in the same soil and upon the same stock, the second plant has grown away rampantly. I find a similar peculiarity in *Marechal Niel*; and this, with *emker*, are at present imperfectly understood.—P. U.

— This *Rose* does well as a standard in the West of England, but I do not remember having seen it trained on an arch. In a fairly good climate I should not mind risking it. The growth, however, is rather slender, so that the wind would probably do it more injury than cold. Trained to stakes about 4 feet high in the form of a hedge it does well with me on a sheltered border. The plants are in their own roots, and make splendid growth.—J. C. C.

— W. A. Richardson will do very well on an arch if not exposed to cold winds, as also will *Gloire du Dijon* and most of the *Dijon* *Teas*. *Cheshunt Hybrid* is a beautiful covering for an arch.—R. H.

5217.—*Rose Charles Lefebvre*.—Yes, this is one of the hardiest and most reliable bloomers we have. In a former query you ask about *Tea* *Roses* by the sea, so I presume this *Rose* is intended for the same position. There is a climbing variety of it which will produce a quantity of deep velvety blooms in great contrast to the *Teas* I previously recommended.

It may be of service to name half a dozen good dark velvety-red *Roses* as a counterfoil to the *Teas* already mentioned in Query 5215: General Jacqueminot, Fisher Holmes, Mme. V. Verhier, Prince C. de Ruban, Dr. Ballion, and Duke of Edinburgh.—P. U.

— Yes, this is a really splendid variety, hardy and vigorous in growth, and remarkably free-flowering, the blossoms being of a rich velvety crimson colour. It is frequently included in the "best dozen" of this class.—H. C. R.

5215.—*Tea* *Roses*.—A good six varieties for your garden would be *Anna* Ollivier, one of the most beautiful of all *Tea*-centred *Roses*, the flowers very full, and a rosy shade, touched with flesh, and hard, whilst the plant is vigorous in growth. *Devoniensis* is a very fine flower, creamy-white, large, full, and of beautiful form; it is an old but first-class variety. *Mme. Hoste* is a well-known *Tea* *Rose*, the flowers of a pale yellow shade, deepening in the centre, and of very fine form; it is in every sense of the word a valuable kind, hardy, a good grower, and blooms very freely. *Mme. Lambert* is one of the most useful of all, a hardy, free, and distinct kind, the flowers varying in colour, usually of a rosy shade. *Marie Van Houtte* is one of the most popular of all *Tea*-scented kinds, the flowers being produced freely, and of a rich canary yellow colour, deepening in the centre, the petals margined with a bright-rose shade. Another old variety is *Souvenir d'un Ami*, raised in 1846, the flowers, as doubtless you well know, being shaded with rose and salmon, large, double, well-shaped, and borne freely, whilst the leafage is extremely fine. Those mentioned are by no means new, but all indispensable in a small collection.—C. T.

— If "Anxious" had been more particular and told us his situation respecting exposure to wind from the sea, his query could have been more definitely answered. I know many gardens in Brighton and Eastbourne where *Roses* do well, others where they are failures; in fact, it was only courting failure to plant them in such. It does not matter how near the sea your garden is so long as the unbroken winds do not play direct upon the *Roses*. Very few gardens do face the sea-breeze; but I have seen many attempts to grow climbing *Roses* upon the exposed fronts of houses. This is utter folly; the sea-breezes are too much for them. But if in a sheltered back garden, then the following six *Roses* will do very well: *Anna* Ollivier, *Marie Van Houtte*, *Sufrano*, *Dr. Grill*, *Mme. Lambert*, and *Perle des Jardins*. "Anxious" does not state if they are wanted as climbers or not. Six good climbers would be *W. A. Richardson*, *L'Idéal*, *Climbing Perle des Jardins*, *Gloire du Dijon*, *Cheshunt Hybrid*, and *Mme. Bernard*.—P. U.

— *Gloire du Dijon*, *Honore*, *Souvenir d'un Ami*, *Reine Victoria*, *Marie Van Houtte*, and *Mme. Lambert* are all *Roses* of robust growth that thrive well near the sea. October is probably the best month in which to plant these, certainly if the soil is moderately light and warm, and the position not too exposed or cold.—B. C. U.

5226.—*Tea* *Roses* in pots.—There are so many good *Tea* *Roses* suitable for growing in pots that no two people are likely to mention the same varieties. My choice, however, would be *Niphopha Lucile*, *Mme. Falot*, *Marie Van*

Hortto, Grace Darling, Safrano, Perle des Jardins, Letty Coles, Catherine Mermet, The Bride, Mme. Lambert, and Anna Ollivier. You do not say how large your greenhouse is, or the size pots you intend growing them in. My advice to all amateurs, however, is that you continue giving the plants two sizes larger every year until they reach those 12 inches in diameter, even if a less number of plants be grown, as large plants are not only less trouble in watering, but in comparison to small ones a much greater number of flowers are obtained. A strong plant of Niphetus in a 14-inch pot will flower more or less from early spring to late in autumn.—J. C. C.

— You will find it best to purchase plants in pots. These will give you a good crop the first year, which plants potted up from the open would not. I would suggest you purchase them in 6-inch pots, and send the following eighteen names, with permission to the florist to send which he has best plants of: Anna Ollivier, Mme. Lambert, Rubens, Mme. Filent, Niphetos, Jean Ducher, Edith Gifford, Catherine Mermet, The Bride, Sunset, Perle des Jardins, Mme. de Watteville, La Boule d'Or, Françoise Krüger, Dulce Bella, Comtesse de Nakhillic, and Mme. Hoste.—F. U.

GARDEN WORK.*

Conservatory.

With the lengthening days will come the need for more water at the roots of plants in flower or in active growth. As the days lengthen the soil will strengthen, is an old familiar adage that will perhaps be exemplified this season, and this will render necessary more frequent watering to keep up the requisite temperature and moisture for the plants. A watchful eye is kept, will stimulate the production of insect pests, and all this tends to prove that a gardener has very little leisure for anything beyond his daily round of duties. Perhaps it is as well that it should be so. Men or women with duties to perform are always better and busier in harness. Forced flowers are coming freely now, and will include lilies in considerable variety. Frosties are charming now, and are so easily grown that everybody should have them. May be grown in a light window, the first lily, may in flower, were potted in August, and they have been growing in a house where fires were only used occasionally, when the nights were cold and damp. It is very important to keep them near the glass, as light is essential for the formation of a sturdy habit. Begonias should now be placed in the flowering pots. Good loam, freely enriched, will do them well. The pots must be well drained, and the soil removed in freely. Firm potting induces a sturdy habit, and increases the number of flower buds. Strong shoots should have the terminal bud rubbed out. All plants, when they begin to grow freely, are the better for a little pinching to secure a bushy habit. Tall lanky shoots need staking, and lead to nakedness of the base. Young Fuchsias that were struck last August, and which have been kept in a cold winter, will be ready now for 6-inch pots, in which they will bloom early, or if larger later-flowering plants are required, they may have a shift early in March into 7-inch pots, still keeping them in a house where fire-heat is regulated, and giving the syringe freely over them on the sunny days. As soon as the berries fall from Solanums, shrubby huck, and put in cuttings if more stock is required, or sow seeds. *Centaulia gracilis*, when well grown, is a very effective plant, and is so very easily managed, strong plants lifted from the border and placed in pots that will just hold the roots will flower well the same season, though it would hardly be advisable to force hard, or the flowers will be small. For early forcing the plants should be established in pots, and this refers to many other subjects. But *Chlorodendron* lifted from the beds with balls unremoved, force well without any preparatory treatment, and the same may be said of *Azaleas*; the roots form a dense ball, and moving does not give any check. Do not overwater *Primulas*. A collection of the Double *Primulas* will be effective now. They are not difficult to grow if they receive cold-frame treatment all summer.

Unheated Greenhouse.

Even when furnished with hardy, or nearly hardy, plants alone, there may be flowers. A collection of *Heliochloa* (*Christmas Roses*) will be interesting now in most people. The *Christmas Rose* is known only by its common representative, *Heliochloa niger*, but improvements have been effected in this family, as in most others which have come under the hands of the hybridist. There are several varieties of *niger* with larger flowers, and which are better adapted for pot or intermediate than the type, and besides there are *Heliochloa* with red flowers, or, at least, in which red predominates. The owner of the unheated house might do worse than get a collection of *Heliochloa*. In the summer they could be placed outside to make room for the *Tuberous Begonias*, *Lilies*, *Fuchsias*, &c. There are several varieties of *Laurustinus*, which flower freely in winter in tubs or large pots, and the Naked-flowered *Jasminum* would be bright and useful.

Stove.

The principal work here just at present is to thoroughly clear out weedy-logs and other insects. If this is not done now, by and-by the work will so increase it will be impossible to do it. The only way to make sure work is to hunt them up, not only on the plants, but in every crack and crevice about the house, and when all the plants have

been cleared with the sponge and whatever insecticide is used, go over the paint and walls, and if the house contains a plugging bed, clear that out also, and refill with fresh litter, or leaves, or sawdust, or whatever is used. The deciduous and other creeping plants which are partially dried off during winter may soon be pruned back in ripe wood, and as soon as there are signs of growth ripen. No store is properly furnished without an *Allantaria* or two, and they flower best when trained near the glass. They will do very well in a large pot, or in a basket on a side-shelf over the hot water pipes, or other moist chamber, or in the *Lipidifera*, *Clerodendron*, *Banquo-villars*, and *Stephanandra*, all of which will need somewhat similar treatment; but they will not be much exceeded at night for the present. The house will still be gay with *Dreidias*, *Chorodias*, *Begonias*, *Euphorbias*, *Primulas*, &c.

Ferns under Glass.

Sow spores now in pans or boxes, and place in a dark corner, where the sun will not reach them. It will be an advantage if the pans or boxes are covered with squares of glass. If kept constantly moist, without much watering, the good seeds will grow. In a house devoted to ferns, the seedlings spring up everywhere, in coal-ash beds or freely as anywhere, showing that if the seeds are good, and they fall on a moist medium, they are sure to grow. In another part of the same house the ground has been covered till the clay is reached, and here, on a thin stratum of ashes, the *Ferns* come up as vigorously as anywhere. One of the most useful *Ferns* for rooms and general furnishing is *Pteris* (*Pteris*), and this also comes freely from spores. It will be well after the first soil for potting. Good loam should form the main staple.

Bedding Plants.

Any plants required to furnish a large stock of cuttings should be placed in heat. But the majority of bedding *Pelargoniums* will do in a cool-house for the present, well ventilated, and not watered too freely. *Geraniums* will go for a long time without watering when the temperature is low. *Cactaceae* are well rooted now in the cold frames, and may have the lights opened in every day.

Cold Frames.

Damp is all we have to contend against up to the present, and this may be met by increasing the ventilation. Hardy plants, such as *Thompson Stocks*, *Double Wall-flowers*, *Polemoniums*, *Antirrhinums*, and other things, may have the lights opened wide every day, when not freezing or raining. *Violets*, also, must be freely ventilated.

Window Gardening.

Asparagus plumosus is a very unamiable room-plant, and is not difficult to keep in good condition, and when the fronds lose colour, if the whole plant is cut down to the ground a new beautiful growth will spring up immediately. Very few plants now will require watering more than twice a week, unless they are placed in a warm position, but the foliage must be kept free from dust.

Outdoor Garden.

The early-planted *Primulas* will now be well established, and frost, if it comes, will not disturb them injuriously. Those planted late often get killed by frost before they are well established, and the drying effect of the frost does much harm. During frosty weather the late-planted things will be much benefited by a mulch of old garden soil. Up to the present we have not had much frost, but there has been plenty of wind and water, which has made the planting operations on heavy soil rather sticky work. In planting any thing we wish to succeed, it is a good plan to have a heap of dry stuff in the compost-heap, so as to have a shovel or two to shake in among the fibres, and then gently shake the tree or shrub to settle it before treating it. When the soil is very wet, the bedding may be left till the surface has dried somewhat. *Wet* or *Moss* walks should be formed, and then made firm again. This is the cheapest and best way of renewing the surface of worn or heavy walks; if convenient, a little fresh gravel may be placed on the surface at the finish, grading may be done now. It is very important that positions for *Roses* should be drained if the soil is heavy and damp. Among evergreen hedges *Yew* is both cheap to plant and easily kept in order. It is not suited for a boundary fence, because it is poisonous to sheep and cattle, but for an ornamental fence or division line in a garden it is very suitable, and may be used in a great number of ways. It is a kind of shelter for *Yew* hedges, cold winds never enter, and *Roses* and other flowers may be seen in the highest state of perfection. A garden without shelter is often in a dilapidated condition.

Fruit Garden.

Cut all late *Grapes* and bottle them in the *Wine*-room, which should be kept at an even temperature of about 45 degrees. Give a look round once or twice a week to remove decaying berries, if there are any, but *Grapes* will cut and wash so much in the *Wine*-room, if the conditions are suitable, as they will hang on. The *Vines*, especially if plants in pots are kept in the house. When the *Grapes* are all gathered in the *Vines* should be pruned, the base bark removed, and the rods washed with a strong lime-water. Every gardener has his favourite mixture; those who have used may use *Blind's Compound*, 1 lb. or 2 lb. to the gallon. Apply it once with a brush. The last of the *Vines* should either be painted, or the paint should be cleaned with soap and water, and the wall surface white-washed, and when the inside borders are laid-dressed the house will be ready for work again. This annual cleansing is very necessary in the case of all forcing-houses, and it is a great mistake to begrudge a little paint. Garden assistants, if they are worth their salt, can, if needed, do the inside painting. The trees in the orchard-house should be pruned and dressed soon, as the lady will very soon be on the move. Such a man who has been said and written against pulled trees, the demand for them is increasing, and I hope may continue to increase, for it is a most interesting way of growing them, especially for amateurs, who do not require to have large quantities of fruit at once. Keep a steady temperature of 50 to 55 degrees, in the early *Peach*-house. Eggs in pots will do with 50 to 55 degrees. *Vines* breaking into leaf should have 55 to 60 degrees. This refers to slight temperatures only. The rise in the *Peach* house, from 10 to 25 degrees, is a daily season very little air is required, and the sun has but little power.

Vegetable Garden.

If *Peas* and *Beans* have not been sown, the first favourable opportunity should be taken to get in a few rows of the early border. The first of the early peas should be sown, and neither mice or rats will touch them. Those who have no special favourite sowing *Peas* may try the American Wonder and William I. The Dwarf Lion *Peas* are very good for the small garden, and the Early Long-pod is better than the *Mazagan*. Where there is plenty of glass, *Peas* and *Beans* may be started in pots or in some other way. *Beans* transplant very well out of boxes. Sow *Chickpeas* in plant in *Wine*-houses. Get in the digging, trenching, and sowing, as soon as land becomes vacant. Get all early seed *Potatoes* sown by placing them in a light position. Those intended for pre-planting should be placed in heat. Make up hot-beds to meet all forcing needs, and they will be heavy now. *Mushroom*-beds also should be made up in succession. As soon as a bed is exhausted, cut with it, and fill the place with fresh material. Happy the gardener who has a good rainy *Mushroom*-house, as so much can be done with it. More *Sea-kale* and *Rhubarb* should be worked out in succession. The early roots also for salad. Late *Rubies* will soon launch in the genial temperature of the *Mushroom*-house. *Mint* and *Turrago* will soon be wanted in quantity now. See that stock enough is at hand for forcing. Sow a few seeds of *Sweet Marjoram* and *Basil*; it will come in profit. Have a good deal of *Parsley* where it can be easily sheltered. This has been a good sowing for early *Broccoli*. Those plants not so protected had better be lifted, a few of the bottom leaves removed, and then laid in somewhere where the weather can be given. E. HONEY.

Work in the Town Garden.

It is very seldom indeed that we get such a mild Christmas as the one just past, and, considering the high price of fuel of all kinds, it is extremely fortunate that it is so. But though the weather is more like that of spring than winter, this is not altogether favourable to plant the most delicate things, and it is very difficult to get on as trying to make things as well, and in order to prevent serious damage from this cause it is necessary to use a good deal of fire-heat—almost as much, indeed, as if the weather were moderately frosty. In *Wine*-houses and greenhouses the damp is extremely trying, and in order to keep *Geraniums* and others of this class in health it is necessary to keep the pipes almost always warm, opening the radiators twice at the same time on mild days, and closing a little on air on the cold days. On the night is warm and still. Under present circumstances, also, it is advisable to clean and set away the stock of bedding and other plants frequently, removing all dead or decaying leaves, and in the case of *Geraniums* even the stipules also ought to be taken off as soon as they turn red, as they are very apt to collect damp and mildew, and not infrequently cause the loss of a branch, if neglected. Such plants as *Chinese Primulas*, *Campanulas*, and *Cactaceae*, however, enjoy the damp mild atmosphere, and are now growing nicely. There will soon be a little more daylight again, and this reminds us that a fresh routine of work for the coming season will have to be begun. The effect of the lengthening days is not so quickly visible on indoor plants in large towns as in open country places, though a good deal depends upon the position of the house, and also upon the temperature. Except in the very unimpaired suburbs, and where there is plenty of heat available, I do not, however, advise any revivifying, or, to be more before, any lifting of the early; but several kinds will have to be sown very shortly. *Peas* should be placed in heat to supply cuttings, and so forth. January is the best month in which to sow *Turnip*-seed for an early summer crop, though except in very open and dry places the end of the month will be time enough, and in sunny places the middle of February is better than attempting to start too soon. Most of the *Tuberous Begonias* should also be got in from the middle to the end of the month, as the plants will do well, and will bear a great deal of frost. *Hollyhocks*, *Delphiniums*, *Lupines*, and *Thyris* sown now will also flower this season. B. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from January 6th to January 13th.

Finished laying *Peaches* in hot-house. Stirred up and watered the borders where dry. Cut all the *Crocus* *Chilman* and *Lady Down's* *Primes* for the *Wine*-room. Pruned the *Vines*. Should give all the air possible for some time. Sowed *Tomato* seeds of different kinds. I often wish there were a better variety of *Tomatoes*. This friend says you must grow this, and another bothers one about another. A 1 soil, and then we have our own favourites, which, having been found reliable, cannot be discarded; and so in the end we had ourselves in possession of more kinds than we care to have. The old bed, when well selected, comes very nearly smooth, and it is a very free sower. Then, again, a good true strain of *Carters* *Market* *Favourite*, such as I saw last year, wants a good variety to beat it. Many these *Tomatoes* I tried when it was first introduced, and still retain it, and perfection, of course, need to be grown for the main crop, though it is not suitable for early work. Sowed a few *Melons*, as I am still putting in cuttings, as they come ready, of *Chrysanthemums*. The worst feature of the *Chrysanthemum* craze is the necessity to grow so many varieties, as so not to leave out those which are really good, and at the same time to produce a few new varieties. When a person's mind becomes muddled in the matter of flowers, he is sure to be overstocked with varieties. There are certain best times for striking cuttings of the different varieties, and that best time is not the same everywhere; and this has to be found out, an referring, of course, only to exhibition sorts, and to find this out means that several plants of each sort must be grown, and the date when the cuttings are taken marked on the label. All this is of interest only to oneself or to others under like circumstances. Put in a lot of *Violets*, some *Russet* *Italy* *Variegated* and others. The best is *Primula* for planting *Peas*. The best of the present season is *Windsor*, and it will be strong enough to go out in June, and will fill a long row in the garden. Moved a lot of plants

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than those indicated, with equally good results.

from which cuttings are required into heat to warm them up; also moved to forcing-house a lot of Spruces and other things but cut flowers and to come on for the conservatory. Planted Potatoes on hot-bed, the variety being Sharpe's Victor. Filled a warm pit with Strawberries in pots to bring them on, as I want ripe fruit by the end of March. Sowed early Peas and Beans on south border; shall also sow some in pots to make sure of a crop. Shifted on young Fuchsias that were struck last August, and which have been growing on slugs. Made a new plantation of Raspberries, chiefly Superlatre, Home's, and other large sorts. This is a day of big things, and everybody likes big Raspberries. Planted a trellis with some of the best of the Lancashire Gooseberries. Those who neglect these lose a good deal. All they want is to be trained thinly on a trellis in the sunshine, so as to get them well ripened. Trained Heathus and other specimens of hard-wooded plants. I do not believe in filling the pots with sticks, but supports are necessary for specimen plants when they get large. Azaleas also have been gone through, and what tying is required has been done. Looked through the Fern-house; rearranged, picked dead and discoloured fronds. Some plants which have been used a good deal for cutting have been cut down.

5220. — Hot-bed. — The gardener is quite right; the Peat-Moss-litter from the stable is not

FRUIT.

STANDARD PEAR-TREES.

One of our very best Pears is Marie Louise, and so good a variety ought also to be included in quite limited collections of either bush, pyramid, or standard trees. It is the freely or naturally grown pyramids and standards that give the best results, and I need hardly add that the latter should be on the Pear-stock. On poor soils the growth is scarcely vigorous enough, a fairly strong loam best suiting the variety. Unless this can be given, the trees are apt to become stunted and flower far too freely to be productive, there being such a thing as having too much blossom. The season before last the trees generally flowered most abundantly, but the flowers being stronger than usual there were fewer failures to set owing to any inherent weakness, though severe frosts worked sad havoc among the trees. In the case of the tree

to the top of a good dressing of solid manure. There are various other manurial dressings that might be substituted, but I have most faith in manure obtained from mixed farmyards. Not unfrequently the best-flavoured fruit, if somewhat scrubby in appearance compared with that produced by wall-trees, is obtained from pyramids, standards, and espalier-trained trees, but this would be less often the case if the former were kept better attended to at the roots. Marie Louise keeps better than most varieties after it is ripe, the natural season extending from the middle of October to the second or third week in November. This can be improved upon or lengthened considerably by gathering the fruit at different or say at fortnightly intervals, ripening that first picked in heat, and keeping some on the trees as long as they will hang. Marie Louise d'Uccle, which also does well as a standard, is quite distinct from the variety under notice, and, though more productive, is inferior in point of quality. Other good kinds for standards are the following: Hesse, Williams' Bon Chrétien, Josephine de Malines, Swan's Egg, and Pitmaston Duchess. W.

5221. — Pears and Plums. — Six in not very large selection of Pears, but the following are all good, commencing with the well-known Williams' Bon Chrétien in August, Beurré d'Amanlis in September, Louise Bonne de Jersey, October; Marie Louise, October and November; Winter Nelis, November and December; Doyenné du Comice, December. The Plums are, for the most part, in season in September, but you may commence with Rivers' Early Prolific, the fruit of medium size, deep purple in colour, and juicy; Orleans, rich purple, very richly flavoured, August; Coe's Golden Drop, a well-known and delicious variety, end of September; Pond's Seedling, and the Green Gage-flavoured Reine Claude de Bayay, in September; also the popular and free-bearing Victoria, which, when fully ripe, is excellent for the dessert. You cannot do better as regards baking Pears than select Uveitale's St. Germain, a very large and solid fruit, useful only for baking. — C. T.

— Six good Pears for dessert for succession: Clapp's Favourite, Williams' Bon Chrétien, Beurré Superfin, Louise Bonne de Jersey, Marie Louise, Pitmaston Duchess, and Doyenné du Comice. Six good Plums: Green Gage, Coe's Golden Drop, Kirke's, Jefferson, Transparent Gage, and Belgian Russet. The Victoria, if not overcropped, is good enough for dessert. Catillac is a good stewing or baking Pear, and most of the dessert Pears will bake well when green. The Swan's Egg Pear, which makes a large orchard-tree, is a good baker. — R. H.

— The following Pears and Plums will be found to give a succession of fruit, ripening in the order here given: Jargonelle, August; Williams' Bon Chrétien, September; Louise Bonne de Jersey, September; Brown Beurré, October; Marie Louise, November; Doyenné du Comice, December. Plums: Green Gage, August; Early Prolific, August; Jefferson, September; Kirke's, September; Purple Gage, September; Coe's Golden Drop, October. — S. P.

5223. — Planting a Mulberry-branch.

— It depends on the size of the branch whether it will grow or not. If it is not more than 6 inches in circumference there is no doubt but what it will grow. I once knew a branch of the Mulberry to grow that was used as a stake to support another kind of tree, and it developed into a fine, handsome specimen. If such large branches will send out roots it is pretty safe to conclude that small ones would do so if they are taken off at once and 9 inches of the stem buried in the ground. — J. C. C.

— Trunk-lice cut from old Mulberry-trees, planted firmly in the ground in the shade of a wall, will form roots if well watered and mulched, and this is the only way of getting young trees that will bear early. Mulberry-trees are obtained from cuttings and layers. — R. H.

5225. — Destroying mealy-bug. — Cut the Tacsonia back to firm wood, and dress it with a strong solution of Gishurst Compound, 3 oz. to the gallon. It is not difficult to kill mealy-bug on the Tacsonia now, but other things in the house are probably infested, including the woodwork, the ericaceae in the walls, and even the soil in the border, and unless the work of cleansing the collection is thoroughly done there will be plenty of bugs next year. — R. H.

Standard Pear-tree "Marie Louise" in flower.

suitable alone for making a hot-bed, as it gives a great heat for a few days and as suddenly declines. Mixed with leaves at the rate of one third of Moss to the remainder of tree-leaves it will do very well, but if I had plenty of the later I should not use the Moss at all, as the leaves alone will give a longer and steadier heat without it. You may, however, use the Moss-litter from the stable as a manure for all garden crops, and the sooner it is dug in the ground the more good it will do. — J. C. C.

— Yes, a mixture of equal parts of Moss-litter-manure and tree-leaves will make a very good hot-bed. — H. C. R.

— Moss-litter-manure and leaves will make good hot-beds. They are more difficult to construct because neither the leaves or manure bind together well, but with patience it can be done. Cuttings of evergreens are often plentiful at this season, and a few of these may be worked on round the outside of the surface-roots, returning the soil on

figured there are no apparent signs of want of vigour, yet the blossom was most abundantly produced, the tree when photographed presenting a most beautiful sight, and that, too, in spite of the comparative smallness of the flowers of this variety. When standard Pear-trees are in the happy condition shown in the engraving something is necessary in most cases to be done towards sustaining their vigour. Where good loam is available, it pays well to add one half hundredweight of half-inch bones in every hampel up cartload of it, and to place this in a trench well within reach of the roots. Especially are such additions to the border necessary where it is desirable that the trees should continue to grow strongly without their productive powers being impaired. The next best thing is to dig the surface-roots, returning the soil on

FERNS.

TWO GOOD HARDY FERNS.

SCALE FERN (*Ceterach officinarum*).—In reply to "Fern-lover" and "Fili.ca," this is a distinct and beautiful little native Fern (see Fig. 1) admirably adapted for rock or alpine gardens, as it thrives best when planted between the clefts of rocks or stone walls. It is a Fern that, unlike most other varieties, dislikes a confined, damp position; hence it can be planted in the most exposed places with good effect, and, with a little careful attention to its simple requirements at the outset, with almost certain success. The clefts and crevices wherein it is proposed to plant this *Ceterach* should be filled with a mixture of sandy peat and pounded limestone. It might be associated in such positions with some of the little flowering Sedums, and various other plants for walls and stony places.

MALDEN-HAIR SPLEENWORT (*Asplenium Trichomanes*) (Fig. 2).—A perfect little gem is this evergreen among British Ferns, and one that should be grown in every collection. It grows naturally in the crevices of walls or rocks, I have never met with its two or three varieties wild, including incisum and cristatum, although I notice them sometimes offered for sale; this little species is well suited for Warlian-cases on account of its size, and, contrary to the usual rule, shade is not essential, although preferable. B.

The Bird's-nest Ferns.—These are markedly distinct Ferns, and when well grown are splendid ornaments either in the fernery or when seen amongst other plants. There are two distinct varieties of this Fern, one having comparatively narrow fronds with the growth more spreading. The other has much broader fronds and is of a more erect growth. The first-named is entituled as *Thamnopteris unistachasia*, the other as *T. nidus*, both being also found under the genus *Asplenium*, to which in all probability they belong, one being a form of the other, but markedly distinct. The last-named (*T. nidus*) is by far the better kind to grow. It is whilst still in a small state quite an ornamental plant with its broad, massive-looking fronds. I have grown it as an exhibition plant in from the small state until the fronds measured quite 6 feet in length. It does best in the warm-house, a stove being much safer in the winter than a greenhouse. Shade is also needed, whilst slugs and snails, as well as black thrips, must be very closely watched for and destroyed. A peaty soil and moderate potting suit it best. The soil should be rough (as used for Orchids), with some charcoal and broken crocks when it is not full of fibre; a liberal supply of water is also needed. —F.

Anthurium Andreanum.—This *Anthurium* has never attained the degree of popularity that was anticipated at the time of its introduction, but, for all this, it must by no means be passed over, for it is a wonderfully showy flower, and one that will remain bright and fresh for months. While its flowering season can scarcely be described as limited to any particular period of the year, where a few plants are grown some of them can be depended upon to flower during the winter, and just now I have several examples in bloom which will remain fresh till spring. The loose, somewhat scaunt habit no doubt detracts from the popularity of this *Anthurium*, but with regard to this feature, individuals vary greatly, some being far more tufted in growth than others; still, the finest flowers are as a rule borne by the strongest growing ferns. It ripens seed freely, from which young plants can be readily raised, while it has also been employed by the hybridist, and, in conjunction with the white-flowered *A. ornatum*, has given us a race of pinkish-throated ferns, which, though pretty and useful for their free-flowering qualities, are not nearly so showy as a good form of the typical *A. Andreanum*. One of the best coloured flowers of this *Anthurium* that has ever come under my eye was shown last spring from the grand collection

that Sir Trevor Lawrence has gathered together. It was awarded a first-class certificate by the Royal Horticultural Society under the name of *A. Andreanum sanguineum*. One of the first hybrids in which *A. Andreanum* played a part was *A. ferriereense*, which still remains among the best of its class. —P.

THE AURICULA—SHOW AND ALPINE.

This pretty spring flower begins to get very interesting soon after the new year comes in, especially if a good collection of the best show

Fig. 1.—Scale Fern (*Ceterach officinarum*).

varieties is grown, for if the plants are grown in a heated house the leaves slowly unfold soon after Christmas. There is considerable difference even amongst the best cultivators as to the treatment of these choice alpine plants. I was once talking to a good grower and successful exhibitor of Auriculas, their winter treatment being the theme, and my friend seemed quite surprised when I stated that I liked to expose the plants to a good hard frost. His treatment was the very reverse of this, for he hurried his plants into a heated house as soon as frosts set in, and did not like them to be exposed to a lower degree of cold than about 35 degs. Fahr., this overcareful treatment making them quite greenhouse plants. I find when the plants have been exposed in cold frames to a rigorous winter we have very little of the woolly aphid, seems rather tender, and cannot endure being frozen for a week or two at a time. I fancy if Auricula fanciers were to return to the old-fashioned way of frame culture entirely, never allowing the plants to go into a greenhouse, we might have less bother with this troublesome parasite. The great advantage of a heated house for Auriculas consists in the facility with which the plants can be protected when they are in blossom. The flowers of these garden

Fig. 2.—Malden-hair Spleenwort (*Asplenium Trichomanes*).

favourites are more fragile than one would suppose. They suffer sadly from damp, and frost is ruinous to them. From an ordinary garden frame frost may be kept out by duffle mats, but these encourage rather than defy damp; whereas in a heated house or pit the blossoms are not in the least injured either by the damp or the cold. About the middle of January, or at least not later than the first week in February, I place my plants in a pit heated sufficiently to keep the frost out, but I do not mind the temperature falling so low as the freezing point, as this I find does no injury to the plants

delicate flowers when the air is dry, for I am careful to see that the atmosphere is dry when a low temperature is expected. At this season of the year the plants require very little water indeed, and it is usually applied to them early in the day, so that the paths, &c., may be dried up before the house is shut up in the afternoon. Artificial heat should be applied very carefully and only to keep out frost. An important part of the cultivation of the show Auriculas need to be the surface-dressing, which was always considered an essential part of their culture, and no good grower would venture to leave this out of the year's work. I regularly surface-dressed my plants for years, and generally found that few or no roots were found in it at the time the flower-trusses were fully developed. I examined plants in other gardens near Manchester where very much richer dressings were used, and found the results the same; so it was gradually dropped, and the plants seemed to do just as well without it.

GREEN-FLY is the most troublesome parasite we have to deal with amongst Auriculas; it is more partial to the green-leaved varieties, not caring to attack those with the furina densely powdered upon the leaves, although they are not exempt from it. The fine grey-edged variety *George Lightbody* is most frequently attacked, but *Prince of Greens*, *Ber. F. D. Horner*, and other green-edged varieties are much injured unless the pest is destroyed on its first appearance. It is well to fumigate the plants in the house as soon as they have made a little growth, and this will destroy any that may yet be invisible to the naked eye. The trusses and leaves are apt to become drawn up in a heated house, therefore see that plenty of air is admitted, but care should be taken to shelter the plants from frost winds from whatever direction they may blow. The trusses must also be shaded from bright sunshine, which would soon curl up the petals, especially those of the selfs, which, curiously enough, are much more susceptible of injury from sunshine or cold winds than those of the grey, green, or white-edged varieties. In the early spring months the seedlings just pushing out of the ground demand attention. It is better to place the seed-pans in the house with the flowering varieties, as they come up more freely and grow more rapidly, but they do not make very much growth at first, and require some patience to prick out the tiny seedlings which may have just made their first leaves after the two seed leaves. A dozen of these minute plants may be put into a 3-inch pot. The soil must not be suffered to become dry, or the plants may disappear. The offsets put in last autumn will also require to be potted off; some of them are so small that they must be planted in 2½-inch pots, and it is well to repot the whole of them in February whether they be large or small, as they start away more freely in the new soil, which should be a little lighter than that used for the flowering plants.

ALPINE AURICULAS of the choicer named varieties do better in pots and treated very much the same as the show varieties, but the flowers are altogether less liable to injury from cold winds or from frosts. They are nearly all well adapted for planting in the rock garden or for the front lines in herbaceous borders; they like well-drained, good soils, moist in summer. The potting-soil for Auriculas is not quite so important as some fanciers would lead people to believe. I have tried them in the most approved composts of the old growers, and find that they were much in error in the use they made of rich, stimulating manure. The plants, if overfed, are generally short-lived. They thrive admirably in the same soil I use for *Penstemon*, *Pelargonium*, and plants of that kind, such as four parts of good loam, one of decayed cow or horse-mannure, one of leaf-mould, and a sufficient allowance of coarse white sand. The flower-pots should be well drained, and the plants may be repotted once a year during the summer months. Great attention should be paid to watering, taking care to keep free from drought. J 1

OUTDOOR PLANTS.

LEONOTIS LEONURUS.

This rare and curious plant is a native of South Africa, and although the precise date of its introduction to this country cannot be given, it is probably nearly two centuries ago; at any rate it was grown by Philip Miller in the Botanic Garden at Chelsea in 1712. Although when well grown it is a very handsome plant, it does not appear to have ever been much cultivated, and until Mr. Lynch re-introduced it from Ghent about twelve years ago and flowered it in the Botanic Garden at Cambridge, it was apparently entirely lost sight of in this country. Plants of it are now flowering in the large temperate-house at Kew. Until cultivation here it is of herbaceous growth, although very old plants would doubtless become woody at the base. The flowers are produced in whorls from the axils of the leaves towards, but not quite up to, the tips of the previous summer's shoots; they are very brightly coloured, being orange-scarlet. The Leonitis, like the Dead Nettle of our waysides, is a member of the Labiate family, and the flowers have the same two-lipped structure. In this instance they are given a singular appearance by being covered on the inside with short hairs. Each flower is about 2 inches in length, and about forty or fifty of them are borne in a single whorl. The mere growing of this plant is the simplest matter, but, in the neighbourhood of London at least, it is not always so easy to flower. Coming into bloom at a time when fogs become frequent, and being very susceptible to them, it is not unusual for a plant instead of being in flower to be denuded both of leaves and blossoms at this season. But in districts with a clearer atmosphere this danger has not to be feared, and there is no reason why this species should not become as generally known as its beauty and interest entitle it to be. Plants may be grown on from cuttings each year, or they may be kept for two years, but after that period the stock should be renewed. Plunged in a slight bottom-heat, cuttings taken in spring root as readily as Verbenas. They should be potted on as required until they fill 10-inch pots. It is quite necessary to place them out-of-doors in a sunny position during the summer if sturdy-flowering growth is to be obtained, housing them in a cool, light greenhouse towards the middle of September. Strong shoots 3 feet or 4 feet long should be sought after, these producing larger and more numerous flowers. There is, indeed, a danger, in endeavouring to secure bushy, well furnished plants, of stopping the shoots too often, and thus rendering the growth so weak as not to be able to flower at all. Like many of the sun-loving plants from the Cape of Good Hope and Australia, this species succeeds to perfection in the French Riviera, and it is also said to be quite a popular garden plant in Turkish gardens near Constantinople. Both the generic and specific names refer to the conspicuous hairiness of the flowers. B.

Christmas and cover the beds with litter to protect from frost, or else start the bulbs in small pots in cold frames in November, and plant in March or April. I may add that a rather dry position, such as at the foot of a wall where no stagnant water can accumulate, is the best place for this sort of plants, or else the beds should be raised well up above the ordinary level, so that it is impossible for water to lay on or about the bulbs. "F. S." should try a few both ways and compare the results.—J. Groom, *Guport*.

HERBACEOUS PEONIES.

In reply to several queries, to grow these well they must have plenty of room for the spread of their foliage, and a great depth of soil for their roots. A good, moist loam, particularly when enriched by the addition of cow-manure, is the soil best suited to them. They can be planted at almost any time from October to April; but, generally speaking, the best time is in the spring, just as the crocuses are sowing, when a division may be made by cutting them through, as they increase in the same way as Dahlias, the Peonies being very like them in the formation of tubers, which some of them produce in quantity, and grow to quite a large size. The most suitable situation for these herbaceous Peonies is at the back of flower-borders, or in front of shrubs, as there they get shelter

White Peony (*P. alba*).

and show off to the greatest advantage. They also look well as isolated plants on lawns; but wherever placed they must have support by being staked and tied, as their big blooms are a great weight, and bear the shoots down to the ground. Instead of cutting these off when the plants have finished flowering, as is often done, they should be left to ripen and die away naturally, the foliage being necessary, as long as it remains green, to feed and finish the crocuses. The common *P. officinalis* is the typical European kind, and from it the hybrid sorts have chiefly been obtained, and *albiflora*, *sinensis*, and *edulis*, Chinese species, the forms of the latter being particularly fine. The European varieties flower early and the Chinese late, so that the flowering season is considerably prolonged. Amongst the hybrid varieties there is an extensive variety of colours—white, pale-yellow, salmon-flesh-coloured, and a numerous intermediate series between pale-pink and the brightest purple. Among the oldest varieties the following are the most remarkable—viz., *grandiflora* (double white), *Louis Van Houtte*, *papaveriflora*, *rubra triumphans*, *sulphurea plurissima*, *rosea superba*, *Zoi*, *Mdme. Calot*, *Christa Patria*, and *Prince Troubetskoj*. Some of the most beautiful among those of a more recent date are: *Archimede atrorubra*, *Virgo Maria*, *Mdme. Lemoine*, *L'Espérance*, *Très belle de l'Exposition de Lille*, *Jeanne d'Arc*, *Madame Verdier*, and *Mdme. Lemoine*. Amongst others most worthy of notice may be named *Mdme. Lebon*, *Mdme. Lemoine*, *Henri*

Laurent, *Mdme. Jules Elic*, *multicolor*, *Stanley*, *Charlemagne*, *Mdme. Geissler*, *Bernard Palissy*, and *Van Dyck*. Besides these, there are many other commoner varieties—for example, the varieties of *P. officinalis* (such as *anemoneflora*, *rubra*, and *Sabina*), and the varieties of *P. albiflora*, *perogrina*, *paradoxa*, and especially the small-growing *tennifida*, with feathery foliage and large red blossoms. There is also a large double variety of this species; these, as well as the varieties, are perfectly hardy and need no care in winter to preserve them from frost, however severe. Y.

521.—**Daisies on a lawn.**—The surest way of getting rid of Daisies is to dig them out. Weed-killers are not suitable for lawns; they are intended for killing weeds on walks. Lawn-sand is sometimes recommended, but so far as I have seen it used, it acted more as a stimulant to the Grasses than to directly kill the Daisies. Poverty in the soil in many instances is the cause of the Daisies spreading so much, and in such cases a stimulant is beneficial.—E. H.

—Why, as I have frequently mentioned before, not spud out the Daisies, or use an old knife to remove them? The gets rid of them once for all, and no danger exists. But you will find various remedies advertised for killing Daisies on lawns. When spudded out a hole or patch may be left, which can be easily filled up with a new piece of turf.—C. T.

522.—**Plants in a small garden.**—All the plants, or rather shrubs, mentioned may be grown in a small garden—at least, in a garden of fair size. It all depends what you mean by a "small garden." The backyard of a "suburban residence," for instance, would not do for them, I admire your choice. The Japanese Maple and its forms are very beautiful dwarf shrubs, for the colour of their leafage, deep-crimson in particular, a glowing, effective shade, whilst they are quite hardy, much more so than is usually supposed. The Chinese Guedler Rose (*Viburnum plicatum*) is best when planted in a bold mass, the shrub being comparatively dwarf, and charming when wreathed with the ivory-white flowers that stand out conspicuously against the deep-green wrinkled leafage. *Spiraea Thunbergi* is a useful shrub, the leafage turning to a splendid crimson colour in the autumn, whilst the flowers are pure-white, and produced very freely.—C. T.

—If you live in a district free from smoke you could not plant anything prettier than the Japanese Maples; but they require to come immediately under the eye to enjoy the full extent of their beauty, and they should not be associated with any other plants or flowers that are remarkable for brilliant colours. For the front line of a well-kept shrubbery border they are exceeding pleasing. If you get the true *Spiraea Thunbergi* you cannot have a better plant for a small garden. There is, however, such a confusion of names amongst the *Spiraeas* in English nurseries that I do not know where to get the one you mention. To make sure of getting what I wanted, I have imported a lot this autumn from Holland, which I knew at once as being correct by its wiry, arching growth and long, narrow leaves. The Chinese Guedler Rose, if I remember rightly, is not a very choice subject, although the flowers are sweetly scented; the height, however—about 3 feet—would suit your purpose. The Spanish Gorse world, I am sure, please you, as it is dwarf in growth, and continues in flower a long time; and as would the various forms of *Perpetua*, which bears various-coloured fruits.—J. C. C.

—Certainly the shrubs named are suited for both small and large gardens.—E. H.

The Japanese Anemone, and its variety *Homirio Jobert*, or *Alba*, which bears white flowers, are amongst the most useful plants to grow to give flowers for cutting. They both attain a height of over 3 feet, but not near towns. If it is found that they succeed well plant more of them, the white variety in particular, as this will supply more than one hundred of flowers to fill the *epave*. Give them a wet soil and open position. It is essential not to starve the roots, and a mulch every winter will be advisable to maintain their vigour. In the summer copious supplies of water are required, and when the heat years for more of such precious treasures, it is a simple matter to divide the roots, every bit taking, in due course, a respectable plant. Away from the town this

5176.—**Gladiolus "The Bride."**—"F. S." is doubtful about taking my advice to plant bulbs of this *Gladiolus* at once. Let me assure him that his bulbs will certainly be greatly weakened, if not quite spoiled, as far as next season goes if he keeps them out of the soil until the danger of frost is past. My reason for planting in the autumn is from observing that my bulbs left in the soil all the summer start to grow above ground about November; mine are now six inches high, and that even if the tips of the leaves get browned by frost they continue to grow away on the return of milder weather, and flower much stronger than those planted in spring. "F. S." will doubtless have observed that this variety not only flowers much earlier in the open ground than *G. Brauchleyensis* or any of the hybrid kinds, but it also goes to rest much sooner, so that its season of active growth has fully come in November, and trying to "improve in Nature" by keeping the bulbs out of the soil for months after they ought to be growing is a very doubtful experiment. I do not wish to mislead growers in northern districts that they can grow the same things fully exposed that they can in the south coast, but I think they will get little success with *The Bride* out-of-doors if they do not plant by

Anemone will develop into finer proportions; the rose-coloured flowers of the type will deepen, and the white of the variety become clearer. *A. japonica* is one of the richest gems sent to us from the land of flowers. It is well to form, besides a clump in the beds, a distinct mass in another spot in the garden, in order to cut from, then leaving the specimen clump to bloom in its own way. I think so highly of this fine Anemone that it would come into my list of the best twelve hardy perennials.—AMATEUR.

VERBENAS.

OWING to a very destructive disease appearing among these old favourites some years ago, we very seldom see the gorgeous displays which used to be quite common. Like other diseases,

Flowers of hybrid Verbena.

this seems far less prevalent among seedling plants than those raised from cuttings, and as the seedlings will bloom quite as free when treated as tender annuals, I propose giving a brief outline of the method successfully practised by me. It is possible to get seed to produce flowers of various colours, and they come fairly true, so that we can plan for beds of scarlet, white, purple, and several intermediate shades. Should an interloper show among them it can be pulled out without any serious disarrangement of the bed, for the surrounding plants can be pegged down to cover the space at once. Sow the seed by the end of January, either in pans or boxes. Use a sandy compost of leaf-soil, sown thinly, and place in a warm greenhouse temperature. Prick the seedlings off into other boxes as soon as they can be handled nicely, and when settled in the new soil pinch out the points. A distance of 2½ inches between the seedlings will do very well. We shall now be well into March and soon have a spent hot-bed at liberty. Nothing better can be found for the Verbena. Place a little more rich loam upon the bed, and very slightly fork over a little of the manure so that a rich light mixture is obtained. The stopping of the seedlings will have formed them into little bushes, which may now be planted into the frame about 4 inches apart each way. Shut up warm for a few days after having settled the soil around them with water, and then keep them growing freely, but still affording a fair amount of air. Pinch them back once more, and, as the warm days of May approach, remove the lights entirely during fine weather. Healthy, sturdily grown will be the result of this treatment. Verbenas are not so tender as many bedding plants, and may be transferred to their quarters during the middle of June at the latest. Fifteen inches to 18 inches apart is a suitable distance, and if they are thoroughly watered a short time previous to being lifted from the frame, they will come out with splendid balls of roots, in much better condition for quick, healthy growth than if they had been confined to pots. There is also the great advantage of avoiding the most injurious check which neglect as regards water would cause, than which I know of nothing more detrimental to satisfactory growth in the Verbena. Planted in a deeply-moved and rich soil they are more certain to please than any other subject at the same cost and trouble. They will run all over the bed, and yet Digitized by Google

bounds, while the profusion of bloom from the end of June until frosts are prevalent is most pleasing. The chief enemy of Verbenas is green-fly, but these may be killed by fumigation while in the frame, and also by a little care in dusting the affected parts with Tobacco-powder. I quite believe that Verbenas enjoy Tobacco in comparison to other plants. Unchecked growth will almost invariably be clean and healthy, so that early measures are particularly advisable. Generous treatment, care that they do not suffer from want of water, and freedom from insect pests are all easily assured if a little attention is given them. When outside, they will need no more labour, except to water if an exceptionally dry season prevails. At such times, liquid-manure applied cautiously will be well repaid in the greater show of bloom. P. U.

5230.—An old neglected garden.—The first thing to do is to thoroughly work the soil, incorporating plenty of lime, road-scrappings, and similar substance with it to lighten it, and at the same time to enrich it. It is impossible to get good results unless the soil is in condition, and the frosts and rains of winter will sweeten it. Of vegetables you can get all the profitable kinds, Runner Beans, &c., and as you write that a gardener is kept, he will know what to get; besides, you have your own "fancies," so to say, in this respect. Infructuous plants of many kinds may be planted in the spring, and recently several lists have appeared in GARDENING, so no further mention of suitable plants is necessary. If you wish to go in for shrubs the following are good kinds, but will not do in a shady place: Hardy Azaleas, in many colours, which are, however, better for a rather shady position, screened from cold winds; Cotton-asters, *Cytisus praecox*, the White Spanish Broom, *Daphne mezereum*, *Dentzia gracilis*, very pleasing in a light soil; *Escallonia macrantha*, the flowers of which are reddish-erimson, and the leaves deep-green and glossy; Mahonia, Pearl Bush (*Exochorda grandiflora*), the shrub about 10 feet in height, and bearing a profusion of white flowers; *Garrya elliptica*, more often seen on a wall than as a bush, but welcome in the latter form; it flowers in winter when the weather is mild; *Hibiscus syriacus*, flowering in late summer and autumn; there are several varieties, but I care little for those with flowers of dull colours; *Hydrangea paniculata grandiflora*, which produces immense heads of white flowers, a very valuable dwarf shrub; *Leycesteria formosa*, *Magnolia mansipina*, flowering early in the year, the flowers white, cup-shaped, and borne in the leafless branches; *Olearia Haasti*, *Philadelphus microphyllus*, a beautiful dwarf "Mock Orange," producing a wealth of white fragrant flowers; Flowering Currants, the Rose Acania (*Rubus hispida*), *Spiraea arifolia*, the beautiful dwarf-growing *S. japonica* or *S. callosa*, and *S. Lindleyana*, Lilacs, the Gueddar Rose, and the Chinese form (*Vilfarum plantatum*), and Weigelas.—C. T.

I should regard such an undertaking as yours as one of the pleasures of a lifetime. Few things can be more interesting than the renovation of an old garden where fine trees already exist. You have the body of the picture, so to speak, already completed, and all you have to do is to fill in the foreground; and if you do this judiciously you will not have long to wait for results. If I had the work to do I should first take notice of the kinds of shrubs that had made the best growth in the soil previously, and for future planting confine the selection chiefly to the same, as it is only on such lines that you can hope to succeed. There is a good number of evergreens that do fairly well under trees, when the soil is of a friable character, but all will not thrive in a heavy clay garden such as you describe. The common Green Holly and English Yew are as reliable as any for your purpose, so is also the green-leaved *Enonymus* and *Malus Aquifolium*. The White and Yellow Broom will probably succeed if you attend to them well until they get established. Where the soil is the lightest you may try the Aucubas and Portugal Laurel. In any case you must be prepared to break up the old soil before planting to a depth of 8 inches, so that will not injure the roots of the large trees materially, and to incorporate with it some fresh earth, so as to give the new plants a fair start. With regard to flowers, only strong-rooting subjects will be

likely to thrive, and if you want Roses you had better select the dwarf standard form, as the Brier-stock is the best of any for a clay soil.—J. C. C.

— Give the old garden a good clear up, and trench up the borders and quarters 2 feet deep. Apply manure if necessary. Perhaps a dressing of lime will do good. When put into a proper state of cultivation old gardens will grow good crops of all kinds of vegetables. There are no better shrubs for planting under trees than Hollies, Yew-trees, Boxes, Aucubas, and the Oval-leaved Privet. Where the shade is dense St. John's Wort, Periwinkles, and Ivies will hide the bare ground. Hardy evergreen Ferns may be planted in the shady spots. Do something to deepen the soil before planting.—E. H.

— A few shrubs that would thrive best under the circumstances described are the Common, Caucasian, and Round-leaved Laurels (of these the last two are at once hardier and more handsome than the first), Aucubas, common Hollies, Box, Sweet Bays, common Rhododendrons, Lilacs, Privet, Syringas, common and Tree Ivies, and *Berberis Aquifolium*, and others. Among things of lower growth, the Rose of Sharon (*Hypericum*), Periwinkles of sorts, the small-leaved Ivy, Creeping Jenny (*Lysimachia*), Lilies of the Valley, the Yellow Fumitory, Hardy Ferns, &c., are extremely useful, especially among rockwork, &c. Such herbaceous plants as the Spiraea, Primroses of sorts, Anemones of many kinds, including the Japanese, *Aquilegia*, *Myosotis*, *Doronicum*, *Digitalis*, *Iris*, *Eurotheras*, *Funkia*, *Asters*, *Genus*, *Lychnis*, *Helianthus*, *Doronicum*, will also thrive. Of vegetables, Kale of sorts, Rhubarb, Seakale, Leeks, Lettuce, Endive, and Jerusalem Artichokes will succeed better than most others.—B. C. R.

Planting perennials.—For some plants, particularly such as flower in the early spring months, it will be obvious that to plant these the moment they are in flower, or expected to flower, is altogether wrong, as not only does it completely spoil the season's blooming, but it likewise overtakes the energies of the plant at a wrong season, while if the planting be done when growth and flowering are completed, the strength of the plant may be all directed to one important particular—namely, that of becoming established. Nor is this all, for invariably in the autumn there is time for such work to be done well, but in the springtime there is a greater demand upon one's time—so much so that the work is often done hurriedly and too often thoughtlessly, and has to be done over again. Just such an instance occurs to my

Dwarf Verbena for bedding. (See article "Verbena.")

mind. A newly-made border of herbaceous plants was planted last spring. It was about 150 feet long and 8 feet wide. Unfortunately the plants came to hand at a busy time, but as the border was ready, the plants were unpacked and planted in the course of an hour or so, or rather they were put in small holes and a little earth placed round them, and the owner boasted of the rapid way in which the work had been done. The result of all this was that this border was an eyesore all the summer, and only the strongest and most vigorous plants made any attempt to grow. Singularly enough I paid a visit to this very garden the other day, and found it all topay-turvy, and a couple of men digging up the 3-foot-high plants from near the Grass verge, and changing their places with those whose stature was only some 6 inches, and which on the hurry and bustle had been planted at the very back of the border.—E.

FLOWERS FOR PROFIT.

No doubt many readers of GARDENING grow flowers for the double purpose of pleasure and profit, and perhaps a few notes on kinds that do yield a profit may be acceptable to many. The unfortunates are such as grow entirely in the open air, or at the most do not need any special appliances or knowledge to bring them to perfection.

ASTER (CHINA) are most beautiful late summer flowers, and to have them in perfection the seed should be sown in pans or boxes in March, setting them in cold frames. They will need pricking off singly into boxes or frames, so that they may make fine sturdy plants by the end of April, when they should be planted out in beds about 1 foot apart. They may be lifted and sold either in pots or with a good ball of earth to the roots, or as cut flowers they sell readily.

CALIA ATROPICA.—This sells readily at all church festivals. Plants do best as single crowns, potted in 6-inch pots and grown in low houses, or pits close to the glass, and for flowering at Easter they require very little artificial heat, it being the natural time for their flowering.

CHRYSANTHEMUM (early and late).—The early varieties like Madame Desgrange sell readily as pot plants, or as cut flowers, there then being a dearth of good white flowers. About August or September they flower very freely planted in the open-air beds.

LATE VARIETIES that flower during December are more profitable than mid-season kinds. They must be kept very cool and freely ventilated, so as to get them at their best for Christmas markets. Kinds that naturally flower late are preferable to those cut down late in the season, as this weakens the plants very much. White, yellow, and the very dark crimson sell the best, decided colours being most effective in floral decorations.

CARNATIONS are very popular flowers, as they are much in request for button-hole bouquets. When the soil is naturally well-drained Carnations succeed admirably, and are longer lived than in heavy soil, but a good stock of young plants should be layered every year to make up for losses, old plants going off after severe winters, while young stock plants escape. Free Carnations for pot-plants to flower in winter and spring are profitable. A kind called Grenadier, that is readily increased from seed, is very useful.

LILY CANDIDUM.—The common White Lily is a good market flower, the long spikes, if cut before the blooms get fully expanded, selling readily to florists and flower hawkers. I transplant the roots about every fourth year, August is the best month for the operation, the roots being then dormant.

LILY OF THE VALLEY is such a universal favourite that even when the flowers are most plentiful a sale can be effected. The best way to make Lily of the Valley pay is to grow good large beds, and lift a portion every year, picking out all the flowering crowns for pots or boxes, and planting all the smaller crowns out in rows on rich soil, where they quickly develop fine crowns; the portion left undisturbed will give a good supply of bloom for gathering from the open air. They sell best tied up in bunches, with a few leaves mixed with about a dozen bloom spikes.

MARGUERITES.—Both white or yellow kinds have of late been very popular as cut flowers. They sell freely in the early months of the year. From old plants grown in cold-houses during winter, and in the open air good strong plants should be put out in May. The white varieties are the quickest coming into flower, but the yellow, which grow more strongly, make up for loss of time by producing an enormous quantity of fine blooms late in the season.

NARCISSUS of several varieties, such as Pheasant's-eye, Double White, and others, although imported in great quantity, are ever before home-grown ones become ready from the open air, and sometimes realise better prices than those forced under glass. Beds of bulbs succeed well planted between rows of fruit-trees, as the shelter is favourable to them in early spring.

ROSES in open-air beds are much grown as a market flower, but the aim of those who expect profit should be to grow varieties like the Gloire de Dijon that flower more or less the whole season, for during June there is sometimes such a glut

of Roses that very low prices are obtainable, but by the end of July or August very much higher prices prevail. A good lot of Souvenir de la Malmaison and other good autumnal bloomers pay as well as any under glass. Marechal Niel, Niphetos, William Allen Richardson, Gloire de Dijon, &c., are extensively grown. Great quantities are sold at Easter, and there is always a demand for button-hole Rose-buds.

SWEET PEAS tied in bunches are good things to grow. Deep cultivation and picking the blooms as fast as they expand, so that none go to seed, are the main items to make them profitable.

VIOLAS of the single kinds are a speciality with many market growers in the South of England. They require transplanting every year in April in to extra good deeply-cultivated soil, and plenty of water in dry seasons. Red-spider is their greatest enemy; it is easier to keep it away than to cure it if once established.

JAMES GIBSON, Glasgow.

USE OF OIL-JARS.

THE great handsome jars used for bringing the finest oil from Italy to London may be made good use of in the garden. We saw a pair in

Italian oil-jars used for half-hardy flowers.

Mrs. Earle's gardens at Woodlands, Cullinm, used with very good effect—one on each side of the garden door. The best things to put in them would be half-hardy plants, like Myrtles, large Heliotropes, or Oranges, which could be taken intant into the cool greenhouse or conservatory at the approach of frost. — *The Garden.*

INDIAN MALLOW AND THE AFRICAN HEMP.

THESE are two very useful greenhouse shrubs that are not sufficiently known to the amateur, although both are cheap, easily grown, and of considerable beauty; the Indian Mallow (Abutilon) having been grown in this country for upwards of fifty years, and the African Hemp (Sparmannia africana) coming from the Cape of Good Hope in 1700. Both need the same treatment, and will form one of the best winter-flowering subjects it is possible to have. In the Indian Mallows we have a vast range of colour: Emperor, Violet Queen, and purpurea, are three good purples of different shades, while good reds may be found in Chrysom Banner, Fire King, and Scarlet Gem. Some of the yellow ones are also showy and clear, Canary Bird, Queen of the Yellows, and Curlew being the best with me; whites need only consist of Boule de Neige, and with delicate

rose-florum, and Princess Marie from the rose-coloured section, we have a grand collection of varieties. The Sparmannia has a peculiarly distinct flower. The petals are white with a little maroon at the base, the stamens are also maroon-coloured, and the anthers heavily laden with showy golden pollen. Both of the plants now under notice are perpetual flowering, but as we value an extra show of bloom in the winter, I propose describing my method of culture with this object. Cuttings of young wood may be struck with other greenhouse subjects in the spring, and grown on in rich loamy soil until July, when they may be stood outside in the sun until the end of September. Pinch out the growths occasionally, or a lush habit will not be secured. They both commence flowering directly, and it needs determination for the amateur to remove the flowering points; but this will be fully repaid by the greater show during winter, when each shoot will carry immense numbers of blooms until spring. A temperature of 45 degs. to 50 degs. is sufficient, but if a greater flush of bloom is required it may be had by giving a slight increase and a little liquid-manure. In early spring withhold water somewhat, cut them back, repeat

the operation as before. By treating them thus you are certain to have a grand winter display, and as both are unique in character, they are a pleasing addition to our winter flowers. They are readily grown as standards of four to six feet. It only being necessary to confine them to one shoot until the required height is reached, and then head them to form a top. I have seen grand standards grown in a single season, and they look very well among late Chrysanthemums.

P. U.

5113.—Sun-dials.—To set a sun-dial so as to obtain from it accurate time is not difficult, but it requires some preliminary trouble and careful adjustment. First have the dial levelled carefully with a spirit-level, then see that the gnomon is properly angled—i.e., set at an angle to the plate proper to the latitude in which the dial is situated. This angle is the same as the latitude; for instance, in lat. 54°, the gnomon must have its upper edge at an angle of 54° to the plate. This is to be found by a protractor, and as a protractor is usually small, I advise that the angles be extended from it on a piece of card-board so as to obtain greater accuracy. Having angled the gnomon aright, the next thing to do is to orientate it, otherwise to point it due north; I did this with a magnetic compass, remembering that the needle at present points 2½° W. of N. When I had carefully arrived by this means at an orientation, I tested its accuracy by holding a perfectly straight-edged 4 foot piece of wood to the upper edge of the gnomon, and trying on a starry night if the straight-edge pointed at the North Star. All this being accurately done, the dial will tell solar time; but solar time differs from earth time, in a variation which alters daily, and the two times agree only four times a year. This difference between clock and sun can be found in "Whittaker's Almanac," and if a card be hung near the dial, with a table on it of these differences, "Quærit" will have an accurate means of setting his timepieces to the minute. His dial, after all has been done, may be 2" or 3" wrong, but he can find how much the error is, and keep a note of it. Of course the time it shows is local, not Greenwich time, and to obtain this latter, another little memorandum must be recorded on his card.—T. D. LAWSON.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for illustration. The drawings, which will be engraved in the best manner, and will appear in due course in our next issue.

THE KITCHEN GARDEN.

WINTER BROCCOLI.

Good Winter Broccoli are invaluable where a continuous supply of vegetables is required; for, although where efficient means of protection are at hand Cauliflowers or Snow's Broccoli may be had in good condition up to Christmas, there is still a long interval before the so-called early spring kinds can be relied on to come into use. Veitch's Autumn Broccoli is, as is now well known, a most useful early-winter vegetable, for if planted in succession it continues to produce heads from November onwards. I generally set out a large quarter of this and Snow's After Early Peas. I do not dig, but merely level the ground and draw deep drills 2 feet 6 inches apart, making the holes with a crow-bar 2 feet asunder in the rows; strong plants are then inserted with the roots a good depth in the ground, and one good soaking of water starts them into active growth. They do not suffer from drought in solid ground nearly so much as in loosely dug soil, as the evaporation is reduced to a minimum; the growth is also more solid and robust, and better calculated to withstand sudden variations of temperature. I also make later plantings in a similar manner, but in smaller quantities, as in mild autumns they continue to grow very late; in fact, Snow's Broccoli has often come in too soon than too late; but in cold weather Broccoli heads may be kept in good preservation by laying and covering with Fern fronds or litter, which I consider preferable to lifting and storing in pits or houses, as a confined atmosphere soon deteriorates the flavour. Walcheren Broccoli (here figured), when of a good stock, is one of the best winter vegetables in cultivation. There are now also several other good late kinds in cultivation. The names can be seen in any good vegetable catalogue. (1.)

FORCING POTATOES.

Futoku Potatoes are much appreciated by many, not that the quality can be considered so very good when secured very early, but they come in for a dish when the prefix early gives them the passport. Of course, anything like a regular or daily supply of very early Potatoes is seldom looked for, as if so, long lengths of heated pits would be needed. For producing these very earliest dishes I have now for some years relied exclusively upon those grown in pots. The pot culture of Potatoes is very simple, and they grow to a usable size, and if not earlier, at least quite as early as any planted out in heated pits, and the quality is generally better on account of their being enabled to be dried off at a time when this process is the most desirable—i.e., a week or so before being required for use. By also growing them in pots it sets the frames at liberty for later crops. If

THE SETS are not far advanced, or at least not sufficiently so to need immediate planting, the best course is to start them in boxes. The sets should be laid in a single layer on leaf-soil, with a little of the same material sprinkled amongst them, and if kept fairly moist and also placed in a warm structure the sets will not be long in making a strong and sturdy growth. For early pot work 9-inch or 10-inch pots are quite large enough. Free drainage is very essential, for if this should become at all choked the haulm will turn yellow and collapse before the tubers have barely formed. The soil also must be fairly rich, light, and open. I use three parts light loam, one part leaf-soil, and some old Mushroom-bed material with a little charcoal. When ready for the tubers the pots are taken to the structure it is intended to grow them in and there prepared. The pots are about half filled with soil, placing two sets in each pot, covering them with 2 inches of soil, which will allow

for a little top-dressing later on. If the soil is in a fit state no water will be needed until the tops are through the soil, and then only but very little. During the early stages it is much better to allow the soil to become fairly dry before giving water. The main essential for a free, healthy growth is keeping them well exposed to the light, with neither too high a temperature nor too moist. Ours are placed in the Peach-houses or vinerias which are being started, and where they remain until they become too warm or shaded, when they are shifted into another. Later on, as the haulm grows, it will be necessary to place two or three small sticks around the sides of the pot and tie with matting.

Broccoli "Walcheren." Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Norman Blake, Bedford.

THE BEST VARIETY I have tried for pot-work is Sharpe's Victor. Mona's Pride, when it can be had true, is also good, the quality of this being preferred by many. Sharpe's Victor, however, on account of its short top and early tuber-forming, is a reliable kind. Beds formed with fermenting material are liable to lose heat very quickly during cold weather—that is unless the temperature is well maintained with linings. The low brick frames or pits heated with a flow and return pipe are the best. Not that fermenting litter or leaves should be dispensed with in these cases, as a body of quite 18 inches or even 2 feet should be packed into the frame in order to cause a genial heat. Ten inches or a foot of light and fairly rich soil should also be provided for the Potatoes. Drills 4 inches in depth should be struck out a foot or 15 inches apart, in which place the tubers 6 inches asunder. In the meantime between the rows of Potatoes a few rows of Radishes may be sown, or rows of Lettuce planted. Early Paris Market Lettuce may be set out 6 inches apart, when the plants would grow and be fit for use before being smothered up with the tops of the Potatoes. A little ventilation more or less, according to the weather, is very essential to ensure a sturdy and healthy growth. Planted-out Potatoes may easily be kept too wet, and there is also the danger of keeping them too long without water. The soil must be kept fairly moist, and this anyone can easily gauge by greasing a handful of soil just beneath the surface. I have seen people keep the soil so dry that upon a spell of bright weather occurring in March the tops have collapsed when the tubers should have been swelling off. In the majority of instances, however, the forcing of Potatoes has to be carried out by the aid of hotbeds. In my own case I have plenty of deep brick frames for vegetable forcing, and by filling these with fermenting material there is not the likelihood of the heat being so quickly blown out during cold, windy weather. A.

5076.—An Indian vegetable. — The botanical name is *Hibiscus esculentus*, and if it is called Damia. More than I de

not know. I succeeded pretty well this summer in an unheated frame with that other admirable and (in England) undeservedly neglected Indian vegetable, the Dringal or Purple Egg-plant, so I would be glad to try "Lady's Fingers" next summer. I should, however, expect it will want fire-heat in the earlier part of summer, which I cannot give it. The Egg-plant, though a vigorous-growing plant, would have done better, and I completely failed with Capsicums for want of it.—D. S. S., Guernsey.

—Birdce, known as OKRA in West Indies. (1) Remove seed and boll like Peas, and serve with pepper and butter on buttered toast. (2) Boll whole, and serve as before. (3) Curry. The fruit may also be used to thicken soup. *Hibiscus esculentus* is the Latin name. If "R. N." should care to spare me a seed, will be say whether from India or West Indies?—SCROZOR-GENERAL CATTLELL, Sull-mount, Cork.

SOWING VEGETABLE SEED UNDER GLASS.

A GOOD deal may be done, by the aid of glass, to heaten various crops, even without artificial heat, for as soon as the new year arrives we invariably get brighter, even though it may be colder weather, but in closely glazed houses, or frames a good deal of solar heat may be enclosed, which is enough to excite vegetation in seeds, and by the time they are well above ground there is a great lengthening of the hours of sunlight, and careful cultivators who make the most of solar heat can manage, by the aid of external coverings, to keep the seedlings safe until they can be trusted in the open air. The following may be sown at once—

BROAD BEANS, sown in small pots or boxes, soon vegetate, and if carefully hardened off, may be planted out in sheltered borders about the end of March. The Early Longpod and Beck's Dwarf Green Gem are good sorts for the first sowing.

BRUSSELS SPROUTS.—One can hardly get the plants too early, for, unless they have time to make a strong growth, the Sprouts will not be so large, or ready soon enough to fetch the highest price in the market. A box of seed sown now, and pricked off into other boxes as soon as fit, will give plants enough for the first crop.

CAULIFLOWER.—When the supply of autumn-sown plants is deficient, no time should be lost in sowing a box of early Snowball, and pushing the plants on so as to get them put out in April. They will be fit for use very soon after the autumn-sown crop.

CELERY for the earliest crop should be sown at once, as it takes a good while to get plants fit for putting out, and they do not germinate so rapidly as some seeds; but as solar heat increases they will grow more rapidly, and as soon as large enough to handle must be pricked out singly in boxes, about 3 inches apart. Well prepared plants have a great effect on this crop.

CARROTS.—Young crisp Carrots are greatly prized early in the season, and to get a good supply a frame should be filled half full of fermenting manure, and trodden in tight to ensure gentle and lasting heat. On this place about 6 inches of fine rich soil, and sow the seed in drills 1 foot apart. They will soon germinate if kept close, but must have plenty of air on all favourable occasions until they are ready for use.

LETTUCE.—A box of Cos and Cabbage kinds should be sown at once, as they make a quick accession to the autumn-sown plants, and at no time of the year are Lettuces in greater demand than during the early spring and summer months.

MUSTARD AND CRESS are always welcome. A box of each sown about once a week keeps a good supply.

PEAS, if sown in small pots or on pieces of turf, will be considerably advanced. They grow rapidly, but require full exposure on all fine days to harden them well before planting.

RADISHES come on splendidly if sown in a cold frame, and are then beautifully crisp and tender, with or without bottom-heat. The French Breakfast is a capital sort, also Wood Scarlet Frame Radish.

TOMATOES should be sown early, for unless the plants are strong when put out, they will not be in time to perfect a crop before the early frost stops their growth. Sow early, and grow the plants on in cool quarters to get sturdy plants. They will do far better when planted out than those rushed up in strong heat later on.

J. GROOM, Gosport.

INDOOR PLANTS.

BLUE LOBELIA.

This plant is indispensable where bedding-out in the usual form is pursued, for it is so dwarf, and such a continuous bloomer, and of the most intense blue, that no substitute is likely to be found for it; and to have a good supply of strong plants in spring is the aim of all gardeners, and many are the plans adopted for attaining that end. As Lobelias are easily raised in any quantity from seed sown in heat quite early in spring, and grown on in pots or boxes until the time for planting out arrives, this plan is very largely followed; but as the plants must get more heat to push them on to planting-out size than what is necessary for plants grown from division of the old plants, or cuttings struck in the autumn, it hardly needs any argument to prove that the cooler plan will produce the strongest plants, and is the one I always adopt in preference to that of raising seedlings. The way I like to get a stock is to put in boxes off a good lot of the latest struck plants after bedding-out is finished in June; these are set out-of-doors, and allowed to grow freely until August, when their tops are clipped closely off, about 1 inch above ground. They are kept moderately dry until they start to grow again, but by the end of September they will be covered with healthy young shoots, and may then be shaken out of the old soil, divided, and divided into boxes of fresh soil. They may be left out-of-doors until the middle of October, when they should be placed in a cool-house or frame—in fact, the cooler they are kept, the healthier and sturdier they will be—and in February they may be divided again. Every little piece will make a good plant, for as soon as they get rooted and start to grow the points of the shoots should be pinched out to induce dwarf, bushy plants. If this be repeated two or three times a stock of dwarf, bushy plants will be assured.

J. GIBSON, Gosport.

THE TUBEROSE.

The December importations of this bulb should no longer be lost sight of. If the first batch has not yet been potted attention should be given to the work, for it is those which will prove very useful when in flower as a change to the earliest Gardenias and Rose-hinds for cool flowers and sprays as well as for bouquet work. For the Tuberose I have a liking myself for the tall pots as used by some Hyacinth growers; these pots give depth, which in the case of this bulb is of importance. In potting, I prefer to keep the bulbs nearly covered, as in the case of Hyacinths, making the soil fairly firm. This latter may very well consist of good turfy loam and leaf-mould, or, failing this, some spent Mushroom-manure worked through a coarse sieve; road-scrappings can also take the place of silver sand if this latter commodity is scarce or troublesome to obtain in quantity. A moderate warmth may at once be given, but no undue excitement until the roots be well advanced, otherwise the foliage is drawn up weakly and the bulbs in a measure weakened also before the spikes appear. After one good watering to settle the soil no more is needed for some little time, the surface being meanwhile covered with a light dressing of Cocoa-nut-fibre to save watering. A dry place wherein to stand the pots should be avoided; a gentle bottom-heat, as from leaves only, in a pit devoted to the early forcing of shrubs, &c., would, on the contrary, be a suitable plan, but then even too much moisture from the syringe should be guarded against. By potting up a fair number a succession can be had later on, for it seldom happens that they all come into flower at one time. As the spikes appear these plants can be drafted to a house or put with additional warmth. Those not potted up at once should not be left in too cold a place, nor be exposed to a drying atmosphere. The better way to keep them is either in Cocoa-nut-fibre or sand where a temperature less than 45 degs. is not the rule. Rather than expose the bulbs I would put all up at once and regulate the succession afterwards. For pots of the size named above one bulb is sufficient, but if ordinary 8-inch pots are used instead three bulbs can be placed therein. Should the bulbs on arrival be found to be

shrivelled, not handling plump, they may with advantage be soaked in warm water for an hour or two; this will be far better than watering freely before roots are formed. When well rooted plenty of water is required, with frequent doses of liquid-manure, or soot-water will answer in its place. A weak solution of this latter will also greatly help to check any development of the red-spider, an insect to which the Tuberose is very subject. For this reason it is never advisable to have it in vineries, or amongst Canniblers or Melons even. The free use of the syringe is for this insect on the Tuberose the best deterrent.

H.

DATURA (BRUGMANSIA).

Amongst flowering greenhouse plants that grow to a large size the Brugmansias stand conspicuous. Strong and vigorous in habit, they require a considerable amount of root-room unless the object is to restrict their size, a course of treatment to which they submit better than most plants that grow large naturally. They produce large funnel-shaped flowers, varying in colour from the white B. Knighti, the double-flowered form of which is here figured, to B. bicolor, the flowers of which are sanguine-red. They can be grown so as to bloom well in pots or tubs, but they are seen to advantage when planted out so as to form a standard, or, still better, where there is room for the growth to extend, as at the end of a large greenhouse or conservatory, where the light they get through the glass, to which the shoots are in close contact, matures the wood and induces the freest disposition to bloom. If in such a position provision can be made to plant them in an outside border as Vines are usually planted, taking the stems inside, but down, and there is enough room for the head to extend, the effect they produce when covered with their large flowers is very fine. Brugmansias increase freely from cuttings made of the joints of the shoots, about 3 inches or 4 inches long, taken off in spring. They should be

4 feet 5 feet in height; the first season the growth should be directed so as to form this erect stem, and to get them up to a handsome size without loss of time. In the autumn when growth has ceased give less water, using no more through the winter than is sufficient to keep the soil from getting quite dry; during this time warmth such as is kept up in an ordinary greenhouse will suffice. About the beginning of March turn them out, remove all the soil, and put them in 12-inch or 14-inch pots, cutting the point of the stem back to induce their breaking several shoots so as to form a head. When they push into growth remove such shoots as are not well placed. Keep the plants in a greenhouse through the spring and summer with plenty of light and air, syringing overhead daily; they may be expected to flower about the beginning of August and September, when they can be placed in a conservatory, where they will be attractive for some weeks. Brugmansias are gross feeders, and must have plenty of water whilst growing, and during the time they are in flower. Through the winter treat as before; each spring turn them out of the pots, remove as much of the ball as can be done without disturbing the roots, replace it with new, and give larger pots or tubs as the plants increase in size. Every spring before growth begins the branches should be well cut in so as to keep the heads within a size proportionate to the place they are to occupy. When they are to be planted out it is better to grow them for the first year in pots, turning them out the following spring before growth begins, and cutting back the stem to induce the formation of shoots. These latter must subsequently be stopped and trained as required to furnish the space destined to be covered. Red-spider, aphides, and most of the other leaf parasites that prey on plants, will thrive on Brugmansias; much will be done to keep red-spider and aphides down by the regular syringing already advised. If merely bog or scale make their appearance, sponge and wash with insect-

OUR READERS' ILLUSTRATIONS: Double Lobelia (Brugmansia) Knighti. Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Armstrong, 5, Clifton Terrace, Moseley, Birm.

put singly in small pots filled with sand and loam, and placed in heat, where they make roots in a few weeks. Then they should be moved into pots two or three sizes larger, with good ordinary loamy soil, to which a moderate quantity of rotten manure is added. After the plants get in growing freely treat in every way as for ordinary greenhouse stock, giving a moderate amount of air in the day with plenty of water and a free use of the syringe daily through the growing season. By the end of June they should have made enough progress to require moving into 8-inch or 10-inch pots. The usual way of having them is in the

forms. The undermentioned are all fine kinds: B. bicolor, flowers red; a large grower; Peru. B. floribunda, orange-coloured flowers; South America. B. Knighti, a very handsome white-flowered kind. B. surcouleana, has immense, drooping, white, trumpet-shaped flowers, which it produces freely; a native of Peru. B. Waymanni, a dwarf-growing, white, and purple-flowered kind; from South America. B.

223.—Herbaceous Calceolarias, &c. —Now and then even a healthy plant will develop a slight variegation in the foliage, but when the leaves of an entire batch become

thing wrong at the root. Either the soil is of an unsuitable character or too much or unwholesome water has been given to the plants. I should advise you to keep the plants rather dry (but not so much so as to cause any of the roots to perish) for a time, and then to dissolve just enough soot in the water to give it a blackish tinge to, say, every other application, and a very little lime also would probably not be amiss. If anything will cure them it is this. The quality of the water supplied to pot-plants has a much greater influence on their health and vigour than many would credit, and accounts for numerous failures. This is one reason why growers in and near London and other cities are able to secure such good results—the water from the mains, though generally a little hard, is always pure and of the same quality. Chinese Primulas are very robust and vigorous subjects, but it is strange that the Cinerarias are not similarly affected, these being of a decidedly sensitive, if not exactly delicate, character.—B. C. R.

RAISING TUBEROUS BEGONIAS FROM SEED.

AMATEURS very often fail in raising plants of this section of Begonia from seed, because they sow too early in the season before they have sufficient heat to bring along the young seedlings. It is not difficult to get the seed to vegetate in a propagator or on a hot-bed even in January, but it is useless at that time to get the young plants up, unless there is a suitable warm structure to place them in as soon as they want more room. Anything less than 70 degs. of heat is not enough at any part of the season, and it is more necessary early in the year than later. If the seed is sown and placed in less warmth than I have stated it will rot before it has time to vegetate. Anyone having a stove or forcing-house may sow at once. But where there is not this convenience they had better wait until the middle of March or early in April. Another source of failure is leaving the seedlings too long before they are pricked off. Waiting until they are large enough to handle is time wasted, as the seedlings make but slow progress when left in the soil in which the seed was sown. The fact is, the surface soil gets sodden and caked over that the plants cannot grow. A stranger to the work no doubt would think that they are not fit to move as soon as you can see them. That, however, is just the right time to move them, and if the handling is done with a pointed stick and the little things gently pressed into some fine warm soil, they will grow away rapidly. Bottom-heat is not necessary after they are pricked off, but they must have a close warm-house, and be shaded from bright sun. I do not, however, advise anyone who is not well up in their treatment to sow the seed before the beginning of March, even if they have the most suitable appliances, as the dry air of a forcing-house is not quite the thing for these Begonias when so young. Plants obtained from seed sown early in March and pricked out in a cold frame about the middle of June will make handsome little specimens by the autumn, and give a good quantity of flowers. J. C. C.

5238. — Cutting down greenhouse plants.—If it is intended to strike cuttings from the new wood the plants named should be cut down at once, and placed at the warmest end of the house. Another way would be to leave the cutting down till March, and then use the ends of the shoots as cuttings. If the Passion-flower is cut back to where the wood is firm will be sufficient. Loam and leaf-mould will grow Passion-flowers. They need not be repotted every year. Use stimulants when the plants are growing.—E. H.

— If the greenhouse is well heated you may cut down all the plants mentioned towards the end of this month (January), and if you keep them as warm as possible subsequently, and frequently syringing overhead, they will soon break into new growth all over, and the young shoots so obtained will make the best of cuttings. In a cool temperature a month later would be better. The Begonias, however (supposing the winter-flowering or evergreen kinds are referred to), need slightly different treatment. Of these cuttings formed of the growth

made during the autumn and winter should be taken in February or the beginning of March, and inserted in a brick hot-bed, the old plants being thrown away. As regards the Passion-flower, if you cut it down, you will lose one or two seasons' bloom; the best plan would be to retain and train up a few of the strongest shoots, and thin out the weaker ones altogether. Plant it in good but not rich sandy loam, with good drainage, but not before the beginning of May. The plants will do far better turned out into a border of soil than in a pot, but if this cannot be done, plant it in a large box. Any pruning or cutting back may be done in March.—B. C. R.

5239. — Hoya carnea.—This plant may be grown well in a good-sized box, or even in a pot, as it requires comparatively little room, and with plenty of warmth and moisture during the season of growth will grow freely in a very small quantity of soil. But there is no need to place it over hot-water pipes, and, indeed, I should prefer to stand the box or pot on the solid ground in any out-of-the-way corner. A light porous mixture of loam, leaf-mould, peat, sand, and brick or mortar rubbish in nearly equal parts suits this plant best. Keep it almost dry during the winter, and give plenty of water and weak liquid-manure during the growing season.—B. C. R.

5240. — Cutting back Hydrangeas.—February is perhaps the best month in which to head back the growth of these plants, the treatment being similar for both the varieties mentioned. Cut back the strong shoots that have flowered back to a plump eye near the base of each, and remove any weak growths altogether. Growth should afterwards be encouraged by means of a genial temperature and frequent overhead syringing.—B. C. R.

5241. — Tuberosus Begonias.—Marquis of Stafford is a fine crimson-flowered variety, of a capital dwarf and erect habit of growth. Virginialis (white) and Mme. Comesse (salmon) are old sorts now hardly worth growing, and Mme. Arnould (rosy-pink), though a good kind, with a fine erect habit, is also by no means new. The others I do not know, but should doubt their being first rate. If you have a well-heated house or pit, or a hot-bed, you may pot and start the tubers early next month (February), if only an ordinary greenhouse, a month later will do nicely. In the meantime keep them safe from frost and moderately dry in Cocoa-nut-fibre.—B. C. R.

5242. — Propagating-pit.—At a sufficient depth below the sash to allow of 3 inches of Cocoa-nut-fibre being placed in it, in which to plunge the pots or pans of seeds or cuttings, &c., you must fix a piece of finely-perforated tin, galvanised iron, or zinc, duly supported by cross-bearers. Below this must be a chamber 6 inches or 8 inches deep, containing a metal pan 3 inches or 4 inches deep, and 10 inches or 12 inches smaller than the interior of the pit each way, supported on pieces of thick tile, or the like, 2 inches from the bottom. In the centre of this bottom, which may be of either wood or iron, and solid, a hole rather larger than the top of chimney of lamp must be cut, and this project through about half an inch. Fill the lamp and the tank (nearly), and regulate the wick by means of the button, and in a few hours there will be a nice bottom-heat. Keep the fibre always moist.—B. C. R.

— If I knew whether the light which covers the pit is in the form of a span or flat, I could answer your question much easier. In the first place, the more space there is above the hot-water pan, the more costly it will be to heat it. The most economical way of working a propagator is to have the glass-light only just high enough to receive a pot of cuttings. A space of 9 inches is the most I should allow above for this, as the more air there is to heat in this space the more oil you must burn to keep up the temperature. To convert your pit into a propagator is not difficult. You must have a zinc tray the exact size of the inside of the pit. This tray must be 1 inch deep, and covered with a perforated sheet of the same material. Bearings for the tray will have to be provided by fixing strips of wood on to the brickwork with one or two cross-pieces to support it, and fixed on to the wall already suggested, so as to allow of a space of 9 inches between the top of the tray and the covering of glass. This done you must

take out three or four bricks from one side to enable you to place the lamp under the tray, and over the hole so made in the brickwork a door or slide must be provided to confine the warmth. Half an inch of water in the tray is quite enough, and a covering of Cocoa-nut-fibre of the same depth on the perforated zinc completes the arrangements. I may mention that the glass covering should incline a little to one side, so that the condensation moisture can drain away. If at any time you get too much moisture in the frame you may take the water out of the tray for a day or two. You will gain nothing by commencing propagating or raising seedlings before the beginning of March, unless you heat your house up to 60 degs.—J. C. C.

5237. — A span-roofed greenhouse.—For your purpose some of the older varieties will be just as good as, if not better than, the newer introductions, and naturally less expensive as well. What you want is free-flowering varieties of a robust habit of growth, and for the majority the Japanese kinds will be most suitable, such as Elaine, Mille Læraix, Avalanche, Mme. Louise Leroy, and late flowering Fair Maid of Guernsey (all white), Sunflower, Mr. Garner, Thunberg, W. H. Lincoln, and Fulton (shades of yellow); Sarah Owen, Mrs. L. Jamson, and Boule d'Or (orange); Etiole de Lyon, Comdor, and Viviani Morel (mauve and lilac); K. M. Mlynaux, Cesare Costa, and Garnet (red); Ed. J. Laing, Mme. Baco, and Bonnet Fuit (pink); Mme. de Sevin (rosy-purple), and J. Delaux, Wm. Sewall, and J. Shrimpton (deep-crimson, the last two being new); J. S. Dibben (bright-yellow, new), Boule d'Or (golden orange), and a few more will also be found very useful. In the incurved section the most desirable for ordinary decorative purposes are: Mrs. G. Rundle (white), Mr. G. Benny (pale rose), Mrs. Dixon (golden-yellow), aureum multiflorum (rich-yellow), Miss Haggas (light), Lady Dorothy (brown-apricot), and Princess of Teck (pale-white), and Mrs. N. Davis (rich-gold), for late flowering. Several of the reflexed section would also be desirable, notably Cullingfordi, Hetty Dean, R. Smith, Elric, A. J. Banks, Chev. Damage, La Vierge, and Wm. Holmes.—B. C. R.

5243. — Andromeda floribunda grows best from layers in a bed of peat.—E. H.

5244. — Humea elegans should be pricked off either in single pots or in pans or boxes, and potted singly by and by, and shifted up into larger pots as more space is required. Harden off, and plant out end of May or beginning of June. The Humea makes good centres for beds in the flower garden, or looks well planted singly in the borders.—E. H.

Begonia "Winter Gem."—This is one of the most brilliant of all winter flowers. The extremely dwarf habit of the plant, with its bright-green habit and spikes of bloom sufficiently raised above the leaves to be seen to good advantage, are excellent features. In the stove—not the warm one where such as *Xorax* and *Nepenthes* thrive, but that where the ordinary run of winter-flowering plants, as other *Begonias*, *Pansettias*, and the like, are grown in a satisfactory manner—this choice *Begonia* will find a congenial home. It has, in common with these hybrids which have preceded it from Messrs. Veitch and Sons' establishment, that highly important and noteworthy feature of retaining its flowers in good condition for several weeks. From three to six weeks these flowers will last in good order. This lasting property makes them all the more valuable for cutting from, whilst they may also be grown very successfully within the fog and smoke radius, as I have myself proved. The other two alluded to above are John Inal and Adonis. This trio should be taken more note of by those who are seeking for further and valuable accession to winter-flowering plants.—H.

"Gardening Illustrated" Monthly Parts.—Price 1d. post free, 8d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 8d. Complete set of volumes of THE GARDEN from the commencement to the end of 1892, forty-two vols., price, cloth, £30 10s.

"Farm and Home" Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 8d.

HOUSE & WINDOW GARDENING.

WINDOW HAIRBELLS (CAMPANULA).
No more beautiful window plants can be grown than these. They are easy of culture and, flowering with the greatest profusion, the wonder is that they are not more often seen than is generally the case. Plants placed in pots or baskets in a good ordinary loamy compost are almost sure to thrive well if provided with ample drainage, as when in active growth they require an abundance of water to the roots. When grown in a window these plants greatly enjoy a washing from a warm and gentle shower of rain, and when such occurs they should be set outside to enjoy it. One of the best window Campanulas is figured below.

FLOWERS FOR A ROOM ABOUT CHRISTMAS-TIME.

EACH year brings an enlarged list of flowers which may be had about Christmas-time, and many of these are easy to grow, even for an amateur, if properly managed.

ROMAN HYACINTHS, for instance, need only to be potted early, and taken in the shelter of a sunny window when they begin to grow, to

no check in the way of cold draughts or want of water to do well.

LILIES OF THE VALLEY, too, can be had by Christmas, but require thoroughly good management if they are to have leaves as well as flowers by that time.

SCILLA SIBIRICA brings its lovely little blue flowers to add to our store, and blue is rare at this time of year. These lulls are quite hardy, but will bear slight forcing to bring them on for Christmas without injury.

SALVIA SPLENDENS, with masses of brilliant scarlet blossoms, can easily be brought on in gentle heat to flower by the end of the year, and these with the bright-crimson blooms of *S. rutilans* (the Pine-apple-scented Sage) are very useful for cutting now. Small neat plants of both these Salvias are preferable to large old specimens, for their flowers are out of proportion to a large plant, though they make pretty decorative specimens when about 18 inches high. It is, however, a good plan to keep a few old plants of Scarlet Salvias to utilize for cutting from, so that plenty of flowers can be had for the table. Large plants, potted up from the borders in October, of

MARGUERITES, both white and yellow, if placed in a box or pot of good soil, in a warmed

are very useful to mix with the white flowers which are most common at this time of the year, F. V. Raspail being one of the best for winter blooming. Cuttings taken in spring, and grown on through the summer without being allowed to blossom, give the best results in winter. They should be placed in September in a warmed greenhouse, however (or the sunny window of a sitting-room with a daily fire), to open their lustrous satisfactorily during the cold weather. There are, of course, a large number of other flowers which can be induced to bloom in the depth of winter with the aid of a hot-house; but the above list is compiled for those who have not more than the ordinary warmed greenhouse or conservatory, which is now so general. Even in a cold greenhouse late Chrysanthemums (such as Snowflake) can be had now, and also plenty of Violets in pots or boxes for cutting. Early bulbs, too, such as those mentioned at the beginning of this article, will blossom here without heat from November to January, with Auriculas, Tulips, Hyacinths, and Jaffoils to follow on earlier or later, according to the amount of sunshine which the greenhouse attracts. L. R.

Campanula garganica. Engraved from a photograph sent by Miss Wolley Dool, Edge Hall, Malpas.

flower from the end of November, if desired, those potted in the second batch—i.e., about the first week in September—being in bloom at Christmas. One of the great secrets in getting lulls to flower early is to utilize in the full the sunshine of autumn, which starts them far better than any fire-heat can do.

ROMAN NARCISSI, too, double, and very richly coloured, should be grown by all. They and also the Paper-white Narcissus are easily to be had from November onwards, if potted in relays from the end of August each fortnight for six weeks. The variety grandiflorus is by far the handsomest kind of this Narcissus, the flowers being much larger than the ordinary Paper-white, although these last are very delicate, and extremely suitable for cutting for Christmas table decoration.

VAN THOI TULIPS, too, can be grown to flower by Christmas if potted early, and brought on after the first three weeks in moderate warmth, with an abundance of tepid water. The best plan to grow these is to place them in light sandy soil in a well-drained box, about 8 inches deep, lifting the Tulips just as the flower-bud shows colour (and not before), and placing them in pots or bowls, with as much of the soil as possible adhering to their roots, and keeping them warm and damp until the blooms are open. In this way, the Tulips which happen to open first are utilised together, while those which are later make succeeding groups; they can be poked into china bowls, with wet Moss, if preferred to potting for Christmas

greenhouse, will supply a quantity of blossom for cutting throughout the winter, most useful for vases at all times. One of the best table plants for bright colour at this time of year is

LIBANIA FLORIBUNDA, which is now a mass of red and yellow flowers, which, with its pretty neat foliage, make it a highly decorative plant. The Libania must never be short of water, or it will shed its leaves. It should stand out-of-doors in the sunshine from June to October to ripen its wood, and be potted on both in the spring and autumn, for it needs plenty of nourishment. Libanias are not very delicate, and will stand a few degrees of frost if well hardened; but for early blooming they should be put into a warmed conservatory in September.

ARUM LILIES are not difficult to get by Christmas if they are not only started early in September, but also allowed to go to rest at the end of May. Many growers keep them in bloom till the beginning of July, and plants which are treated thus will not bloom early. They should be turned out of their pots into good garden soil before June begins, where they can rest till the end of August. Potted up then, and well supplied with tepid water, they can easily be brought on, even in a sunny window, to bloom by the end of the year. Those who grow flowers for winter should include

ZONAL PELARGONIUMS, especially those with double or semi-double flowers, which stand much better than the single blooms, both in the room and when cut. Their light and sunny

Pelargonium "Rollisson's Unique."

—These plants years ago were generally cultivated, but are now seldom seen. The beautifully ent foliage of the various forms with their pleasing fragrance caused them to be necessary adjuncts to the old-fashioned posy, but the superseding of this by the modern bouquet has done much to destroy interest in many good old-fashioned plants. Among the scented-leaved Pelargoniums the Unique class form a group by themselves, the members of which are characterised by less-divided foliage than many of the others, a loose, rambling style of growth, and above all by their beautiful brightly coloured blossoms. The finest of this class is that known as Rollisson's, with rich purple-coloured flowers, while besides that we have also the Lilac and the Scarlet Unique. The long clear stems of these Pelargoniums serve them in good stead when used for cutting. They are very beautiful basket plants, and for furnishing a pillar also well suited, while secured to a trellis or supported by a few sticks they form very effective specimens. Like the Zonal section, they are rarely without blossoms, but to flower them well at this season the plants should be thoroughly exposed during the summer and the buds removed. The result will be good, sturdy, well-ripened wood, which will produce an ample supply of blossoms if the plants are kept in a warm greenhouse throughout the winter.—L.

Streptocarpus hybrida (The Cape Primrose).

The order Gesneraceae is a very large one, and is extended over the greater part of the globe. There are no less than seventy-one genera and over seven hundred species. When we remember that these include the Gesnerias, Gloxinias, and Streptocarpaceae we see what an extensive and important order this is. The genus I am now treating upon has been wonderfully improved during the last few years, and the many grand hybrids, as well as their ready cultivation, has made them one of the most popular flowers we have where once they have been grown. As the flowers last a long time, both upon the plant and as cut thorn, and also from the fact that they flower with exceeding freedom for quite four months, they can safely be recommended as one of the most satisfactory plants it is possible to grow. The leaves are handsome in themselves, while the grand variety of colours borne by the Gloxinia-like blossoms make a show that is difficult to beat. Where a briek heat can be commanded they are easily raised from seed. Amateurs had better purchase a few small plants, and grow them on as I will now endeavour to describe. The same compost which suits Primulas and Gloxinias will suit the Streptocarpus. Like the above, they do not care for large pots. A warm greenhouse temperature will suit them admirably, it being only in the seedling stage when they need a stove heat. As they go out of bloom do not afford quite so much water, but never dry them off so hard as the Gloxinia. Nearly every shade of colour is represented among the seedling hybrids from pure-white to deep-purple and magenta, and there are many and various

TREES AND SHRUBS.

HEDGES—ORNAMENTAL AND USEFUL.
 All owners of gardens who live within a short distance of the sea-coast know what an important thing shelter is from the rough blasts that seem to check and even destroy vegetation much more than actual frost, and a garden without a thick screen of evergreens is a hopeless task, as far as getting anything to thrive, for the incessant buffeting to which they are subjected bruises and blights the tops, and the roots suffer proportionally as they get strained and broken by the action of the tops. Amongst the many plants used for hedges the following are the most popular in this locality—viz.,

CYPRESSUS LAWSONIANA AND MACROCARPA.—Two of the best Conifers for making hedges, as they may be removed with safety up to a good size, so as to form a hedge 4 feet or 5 feet high at once, and they do not need much clipping or cutting to keep them thick from base to summit, neither do they present such a stiff, formal look as Yew-hedges do.

EUONYMUS, both green and variegated, is very much used here, as it succeeds admirably by the seaside, seeming to enjoy the saline breezes. It looks beautiful in winter after a drizzling rain.

LAURUSTINUS in several varieties is one of the very best of hedges, and flourishes splendidly by the sea during mild weather. It is covered with snow-white heads of bloom, or the rosy buds that are very pretty. It should be cut back directly the bloom gets shabby, so as to give a good long season for making its new growth. The Laurustinus strikes root freely from cuttings, but requires considerable care in removing after the bushes get large; in fact, they should be transplanted every year to ensure plenty of fibrous roots close to the stem.

HOLLY, variegated and green-leaved, makes a thick, impenetrable screen, and very ornamental. It is not of such rapid growth as the preceding shrubs mentioned, but is very lasting and efficient. It thrives well by the coast.

LAVINIA, both common and Portugal, quickly makes a good hedge, and the bright, shining leaves are highly ornamental. If cut with a knife, instead of shears, it is far less stiff and formal in outline.

IFENBERGUS VIRGINIANA makes excellent hedges, and stands removal well; makes one of the most feathery and light-looking screens, with varied silvery tints.

PRIVET AVALANCHIUM (the large-leaved evergreen Privet) is one of the most rapid growing of all hedge shrubs; grows freely in any soil or situation, and for a wind screen, or to hide any objectionable objects, there is nothing more suitable.

SWEET BAY flourishes well by the coast, and makes splendid evergreen hedges. It keeps green and luxuriant through the fiercest gales.

MIXED HEDGES are favoured by a good many, and certainly are less formal than when all of one kind of shrub is used. A great variety of subjects, both evergreen and deciduous, can be employed in mixed hedges, such as Lilacs, Berberis, Roses, Myrtles, &c., and in small gardens a much greater number of favourites can be included if the wind screen is made to find a place for many that would otherwise have to be left out altogether.

JAMES GROOM, Gardener.

5224.—**Ailanthus glandulosa, &c.**—If it is wanted to keep the Ailanthus dwarf and bushy you may cut it down in February, but the tree-like character of its growth does not indicate that it requires such treatment. If you want to see it assume its natural characteristics you had better allow it to grow its own way. Of course, you are aware it is not quite hardy in all parts of the country. **Dioscorea** is a hardy shrub, which I advise you to plant without cutting it about in any way until you see how its long leaves fits in with the position you give it.—J. C. C.

Put them over in March to obtain the tropical effect produced by abundance of fresh young foliage.—E. H.

The best time to cut these plants down is in the spring, just before the new growth commences.—H. C. H.

5224.—**Grafting a Holly.**—Various styles are usually grafted on the common European Holly, and it is usually grafted and planted in a cold frame in the effects. The grafting may be done any time before growth begins.—E. H.

CLIMBING SHRUBS.

VINES (VITIS).

In reply to several queries: An ornamental climbing shrub some of the Vines are useful in the garden, especially for trailing over trellises, arbours, pergolas, and pillars. There is a similarity in the foliage of most of them, and, therefore, it is unnecessary to describe them in detail. The Isabella Grape (*V. Labrusca*), known also in gardens as *V. Thunbergi*, has

The Charet-colored Vine.

large bold leaves, rusty-coloured beneath, and turning to brilliant shades of crimson in autumn. *V. cordifolia* (also called *V. riparia*) is a North American Vine of rapid growth and very hardy. Other North American kinds are *V. rotundifolia* (the Summer Grape), and *V. vulpina* (The Fox Grape), while from the Himalayas we have *V. humilis*, whose foliage dies off in autumn with brilliant shades of red and crimson; and from China and Japan comes the beautiful little *V. heterophylla humulifolia* (the Hop-leaved Vine), with small Hop-like leaves and berries about the size of Peas, and of a lovely turquoise-blue colour. *V. h. humilifolia* is one of the most valuable of hardy ornamental Vines and is easily procurable. The Common Grape (*V. vinifera*) is, of course, ornamental, but being less vigorous and less rapid in growth than those above mentioned, is not so desirable. Some of the more robust kinds, as the Fox Grape and the Isabella Grape, will climb and ramble over trees to a great height, and, in autumn, will light them up with the fiery lines of their glowing foliage. In planting Vines under trees they should be placed a few feet from the stem, where the soil is less dry and poor. The Charet-colored Vine does well trained to a single stake, as shown in our cut. This Vine, or one very like it, is very commonly grown in the fields in Touraine and other parts of France for colouring wine, and therefore cannot be difficult to obtain in quantity if nurserymen so wish it. It should be planted occasionally in groups on dry banks, as well as against the house and trellises. B.

TRANSPLANTING LARGE TREES.

PLANTING for immediate effect has of late years become a common practice, and in so doing the larger the tree that can be successfully moved the greater the profit to the planter. For several reasons that will be explained hereafter it is unwise in the extreme to remove trees of too large size from one situation to another, specimens of from 12 feet to 15 feet in

height being, unless under unusual circumstances, quite big enough. In some cases, however, as in the embellishing of a new property, the getting up quickly of shelter and screen is the first consideration, and in such cases the quicker the growth and the larger the trees used are much the better. So much depends on the site of the house, and whether this is open to severe winds and to the nature of the soil that the planter will have to be careful in his choice of trees, the sites they are to occupy, and the way in which the work is carried out. It is, of course, unnecessary to say that in the dips of the ground and where natural shelter is afforded the largest trees may be used; whereas on mounds or exposed positions smaller, more sturdily growing and better rooted subjects must be chosen. First of all, after having arranged as to the sites of the various clumps, belts, or standard specimens,

THE HOLES OR PITS should be formed of about sufficient size, or larger is still better, for the roots and balls of earth that it may be intended to insert. In some cases, however, and I have found the arrangement to work well, it is advisable not to make the pit until the specimen has been brought on the ground, and then by taking into consideration its size and shape, the placing of the trees to advantage can be readily done. Another equally good way is to examine the tree that it is intended to remove, and by taking into account its size and branch-spread, the place for its final planting can be readily decided and arrangements made for opening up the ground for its reception. These methods of planting large trees can, however, only be successfully practised where the specimens are one's own or being brought from one part of the estate to another for the purpose of quick embellishment. Where the trees have to be bought from the nurseryman the case will be entirely different, for then the specimens will generally be of about equal size, and forming the pits for their reception will be fraught with no great skill or amount of designing. It is needless to say, perhaps, that the work of planting for immediate effect can be much more satisfactorily accomplished where the trees can be lifted from one's own grounds as then a specimen of any particular size and shape can be chosen. About the making of the holes for the reception of the specimen trees little need be said, the size of the ball of earth and roots being a safe guide as to the depth and width of the opening. But it is much better to have the hole larger than is necessary, and the sides and bottom well picked up and loosened, for the free spread of the roots afterwards. Should the soil be stiff or of inferior quality, the addition of a little good loam or leaf-soil, as the case may be, will be found of great benefit for the newly-planted tree. In lifting the tree a

GOOD DEEP TRENCH should be opened just outside the root-spread, and to the depth that the roots are likely to penetrate, and the soil from this gently picked away and inwards towards the stems of the tree, until the main portion of the rooted mass is arrived at. Then by undermining the mass of roots and working either planks or mats beneath the ball, the whole can be successfully shifted from one position to another. When the ball is not too weighty, a new bass mat sewn, as it were, beneath the ball and the ends gathered up firmly and tied to the stem, will be found an excellent method of conveying trees from one place to another. In any case matting the roots and ball is an excellent plan, and greatly minimises the risk of breaking up the mass when being conveyed to the place of planting. I have found the junker on wheels the best mode of transit where heavy specimens have to be dealt with, but the size, weight, and distance to be conveyed have much to do with the method of removal. A small stout truck placed on wheels about 18 inches high, and which do not come above the level of the body of the truck, has done good work in the removing of heavy trees from one place to another. This truck is 4 feet long, 3 feet wide, and built of stout timber, the wheels being solid and double tyred, and about 7 inches wide. They are placed so as not to come above the level of the truck—a point of great moment, as should necessarily require it, the ball of earth or framework on which it is placed can protrude over the sides of the body without coming in

contact with the wheels. Being very low from the ground is another advantage in lifting the specimens on to the truck. But there are many ways and means of transferring large trees which will occur to the intelligent planter. Having conveyed it to the destined position for planting, the tree should be slid gently from the truck and into the hole prepared for its reception, which can have been arranged as to depth and diameter while the tree is still on the carriage. The soil is then filled in and firmly tramped and the tree staked, this completing the operation of planting. D.

HARDY BAMBOOS.

IN reply to "J. B.," "R. S.," and others, there are many more hardy kinds of Bamboos than people suppose. There are certainly not less than a dozen quite hardy and distinct. The two great essentials to successful bamboo-culture are shelter from cutting winds and plenty of moisture during the growing season. Bamboos are unaltered by the severity of frost, which often intensifies the rich-green colour; but a few days of sharp east wind often suffice to brown all the foliage and sadly disfigure them. There are, however, especially in large gardens, many sheltered spots where Bamboos will thrive, but generally it is by the water-side that they attain to their greatest stature and display their fullest grace. In all situations Bamboos are ornamental, whilst, being evergreen, they are especially valuable, for we can enjoy their beauty the whole year round. There are giants which also grow into trees, and also lowlier kinds which form huge spreading shrubs. In the minds of many, Bamboos are associated with the tropics and a tropical heat; but the tropics do not contain one-half the members of this beautiful family. North China and Japan have given us the best kinds now available for the garden, and these are perfectly hardy. With these we may have all the luxuriance and grace of tropical vegetation in summer and winter. The French have paid much more attention to the Bamboos than the English. Many of the Bamboos made shoots 10 feet long in about a month in summer, and some strong shoots upon *B. Mitis* grow as much as 4 inches and 6 inches in twenty-four hours, as proved by actual measurement upon several successive mornings. The following are the best hardy Bamboos that have as yet come under my notice:—

B. METAKE.—This (here figured) is the commonest, hardiest, and most accumulating of all the Bamboos. It is a strange-growing, large-leaved kind, attaining a height of from 4 feet to 8 feet. Its foliage is the largest of all the tall kinds, the leaves being each about 10 inches long and 2 inches broad. Its stems are very erect, and the branches cluster round them in thick tufts. It is a native of Japan.

B. RAGAMOWSKI is a dwarf species. It might almost be called a dwarf Metake, as it much resembles that species, but is even handsomer, the leaves growing a foot or more in length, and attaining a breadth of as much as 3 inches. So far as I have seen it does not grow more than 2 feet high, but sneaks freely, spreading out into wide tufts of ample and rich foliage. Used as a groundwork to taller kinds or in broad masses in front of them, it would be very effective. It is a native of China and Japan.

B. SIMONI, also from China and Japan, is a distinct and handsome kind, forming huge tufts about 10 feet high. In a young state its habit much resembles that of *B. Metake*, but it is readily distinguished from that species by its narrow leaves, which rarely exceed 1 inch in breadth, but are about 10 inches in length. Its habit is very erect, and the clusters of branches upon the canes are very dense. Under the name of *B. Simoni variegata* is sold a form with narrower leaves, which are striped with white, but so far as I have seen the whole tuft has a half dead appearance, and I should not recommend it, especially as there are one or two really fine variegated kinds.

B. VIRIDE-GLAUCESCENS is the most graceful of all the hardy Bamboos. It is vigorous in growth, perfectly hardy, and surpassed by none for elegance or beauty. In the "Dictionary of Gardening" it is made a synonym of *B. nana*, which is said to be "a rather tender species, requiring to be grown in the stove or green-

house." This cannot apply to *B. viride-glaucescens*, for there is no nana about it, and it certainly is not tender. Moreover, it is said *B. nana* grows from 6 feet to 8 feet high, but *viride-glaucescens* grows 12 feet high, and spreads over a lot of ground. The young shoots are of a purplish-green, but with age become yellow. The branches are inserted at right angles, and arch gracefully, the leaves being about 3 inches long and about three-quarters of an inch broad. Young tufts of this bamboo are exceedingly light and elegant in appearance, and the old canes have such feathery clusters of foliage that they have been compared, and not inaptly, to a group of finely cut Chamaedoreas. This kind should be included in the smallest collection, and if it were only possible to grow one kind, I would have this one in preference to all others.

B. MITIS is the giant of hardy kinds. It is a native of China and Japan, where it is said to attain the height of from 40 feet to 60 feet; but, of course, it will not attain anything like that height in England, although it will grow 16 feet high. It does not spread much, but the canes spring up in close proximity to one another. They are large, and gradually taper to their tips. The branches, which form a slight angle with the stem, are clothed with an abundance of leaves, which are each about 2 inches long and 1-inch broad. It is one of the smallest-leaved Bamboos.

B. AUREA grows both in Japan and China. It somewhat resembles *B. Mitis*, but is of a more erect and rigid habit, and the leaves are rather larger. The canes are yellow, as the name implies, but this colour is only taken on with age. It is a very ornamental species, and somewhat variable. What is known as *B. sulphurea* is probably only a variety of *aurea*, and there may be many other slightly varying forms of it which have given rise to the somewhat confused nomenclature of the genus.

B. QUILLON is a magnificent Bamboo. It is said to be one of the hardiest, growing 12 feet high. The canes are like those of *B. aurea*, but the leaves are altogether larger, especially in a young state, when they are as much as

leaves, which are of a light-green colour. It is not thoroughly hardy.

B. GRACILIS is made a synonym of the above, but it can hardly be so, as it is still more tender; at least, the shoots, being made late in autumn, are usually cut down by frost. But if treated as an ordinary perennial plant, and cut down to the ground each spring, other shoots soon appear, and form graceful tufts of grassy foliage, which looks fresh and beautiful all the summer.

B. HIRONIS, or *B. Hachiku*, is a Japanese kind, which came from M. Latour-Mariac, and it is destined to become popular when well known. It is vigorous and hardy; in fact, last spring it looked as well as any other. It is an exceedingly graceful kind, as the slender canes, arching upwards, branch freely, and the branches are densely clothed with rich-green leaves, which vary in length from 1 inch to 3 inches, and are about half an inch broad. It is well known that several seasons must elapse before a Bamboo reveals its true character; therefore *B. Hironis*, although already exhibiting high qualities of vigour, hardness, and grace, may yet become still more beautiful. Certainly it is a valuable addition to hardy kinds.

B. NIGRA is a graceful species and a native of Japan. In a mature or full-grown state the canes are of a shining jet black hue, but in a young state they are green, and ultimately change to brown. Those fine black canes obtained from this species for umbrella and other handles will hardly be made in England, but, nevertheless, it is a free and graceful variety, with arching shoots and an abundance of small, rich dark-green foliage.

B. VIRESCENS is so called from the violet-black tint of the young canes. It is a Chinese kind and a vigorous grower, attaining to the height of *B. viride-glaucescens* and proving quite as hardy. The canes are freely branched and well clothed with rich foliage. In a young state the leaves are each 5 inches to 6 inches long and 1½ inches broad, but upon the mature or older canes they are shorter and narrower. The clusters of black hairs around the leaf-sheath are very conspicuous in this species.

B. FORTUNEI is a Japanese species which never grows more than 2 feet high and has a slender stem. It might almost be taken for a vigorous native Grass, but it is a valuable plant, nevertheless, and useful for associating with the taller kinds. It is only found in gardens in two variegated forms, which are named respectively *B. Fortunei argentea* and *B. aurea*. These are the only variegated Bamboos worth growing that I have seen. The first-named kind has long narrow leaves, which are striped with white, and the variegation is effective, constant, and very enduring. The variety *aurea* has broader yellow-striped leaves, and the colour is apt to fade towards the end of the season, but in spite of this it is a handsome foliage plant and well worth cultivating. The following somewhat new hardy kinds are highly spoken of: *B. Boryana*, *B. Marliacea*, and *B. Castillonii*. The last-named kind is especially interesting, as it is one of the curious square-stemmed varieties, two sides of the stem being green and the other two sides yellow, whilst the leaves are striped with yellow, the variegation proving both regular and constant. It is a vigorous grower, and should soon become common in gardens. H.

A hardy Bamboo (*Bambusa Metake*).

5 inches long and 1 inch broad, whilst the clusters of hairs beside the leaf-sheath are larger and more conspicuous in this kind than in any other of what may be called the *aurea* type.

B. FALCATA.—This is often called *Arundinaria falcata*. It is an Indian species, and probably, next to *B. Metake*, the commonest Bamboo in gardens. It grows from 3 feet to 6 feet high in gardens generally, but in favourable situations it often attains to double or treble that height. The canes are slender, but freely branched, and densely clothed with a profusion of

vigorous growth, and should soon become common in gardens.

SHU.—**Yew from cuttings.**—The common Yew may be propagated from cuttings. Make up a bed of sandy soil in a shady place. Place a frame on it—a handlight will do and only a few cuttings are put in. The best time is the end of August or beginning of September, and the further we get away from that time the fewer the cuttings that will root.—E. H.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS ABOUT CHRISTMAS-TIME.

A SUPPLY of Chrysanthemum blooms about this time is perhaps more appreciated than at any other period of the year. Apart from the value of the flowers in the conservatory, they are almost indispensable in a cut state for church ornamentation. No flower will withstand the change of temperature with impunity so well as the Chrysanthemum, and for that reason they are doubly valuable in a cut state for Christmas decoration. Now is a good time to make a selection of suitable varieties; given this and a structure to flower them in that is damp-proof, and there need be no difficulty in having a quantity of flowers when Christmas in 1894 comes round. It is perhaps less easy to cultivate the plants on the large-bloom method, and retard the expansion of the blooms so as to have this class of flower in at the time named, but if the plants are managed on what is known as the "bush" system, there need be no difficulty at all to have flowers in quantity. The cuttings should be inserted without delay, so as to afford the plants a long season of steady growth, so that the stems may become thoroughly matured. Pinch out the point of each plant when about 4 inches high, repeating this operation when 5 inches more growth has been made. Afterwards allow the plants to have undisputed sway, encourage them to grow freely by maintaining the roots in a proper state, never allowing them to suffer for want of moisture; neither should they have too much repeatedly. Freedom from insect pests is decidedly in favour of success. It is impossible for a free growth to be made if green and black fly hold sway over the points of the leading shoots. Mildew also must not be permitted to obtain a foothold upon the foliage. It is the flowering of the plants from what are known as terminal buds that retards their development as compared with the plants managed to give large blooms. These "bush" grown plants supply flowers not only in greater profusion, but they can be cut with long spikes, each having a cluster of flowers at the end, and which is so much more convenient for arranging in vases. If a few blooms are required of larger size for any special purpose these can be had by thinning the flower-buds that cluster around the central one, thus giving additional opportunities for the single bud on each shoot to swell to a greater size, and finally to develop larger blooms. The following sorts I can recommend to provide blooms and colour in variety as circumstances require by individuals. White flowers are perhaps more sought after than any other kind, therefore I give these the premier notice. Mme. Mezzani (swirl-like petals, free blooms, free flowering), Lily Lawrence (creamy-white, slightly incurving florets), Plean (long florets, pure white), Potter Palmer (snow-white, very free, long florets), Florence Davis (opens with green centre, which passes away with age), Beauty of Exmouth (recurving florets, ivory white), Ethel (stout erect petals, pure-white), Fair Maid of Guernsey (long florets, stiff habit of growth), Stanstead White (incurving petals, pure-white). All the above belong to the Japanese section, the following also are white flowered are of the incurved type: Princess Teck (opens pink, passing with age to white), Lord Eversley (a sport from the preceding, pure-white), Miss Marehau (a loosely incurved flower), W. H. Lincoln (one of the best of yellow flowering varieties, dwarf and free), Peter the Great (pale-lemon), grandiflorum (incurving florets, orange-yellow), Mrs. A. F. Spaulding (bronze-yellow, free and effective), Boule d'Or (yellow, tipped bronze), Beauty of Castle Hill (long wiry petals, pale yellow), E. G. Hill (quite one of the best, orange-yellow), Leon Frache (bluish-white), M. E. A. Carrière (pale-pink), Mrs. E. Beckett (rose-pink), Louis Boehmer (silver-pink, hirsute florets), Étoile de Lyon (as a bush the flowers are pale-lilac, very free, one of the best), W. W. Coles (bronzy-red), Comte F. Lurani (silvery-pink). All the above coloured varieties are of the Japanese section, the following, free flowering apricot-yellow, Gablem Gem, is more a reflexed variety. E. M.

5134.—Outdoor Chrysanthemums.—You can take cuttings off now if an open

during the next two months. The suckers which come up through the ground some distance from the stem make first-rate cuttings. After they are struck and growing on in pots or boxes they may be pinched once or twice, which will make them dwarf and bushy, but they will not require to be pinched after being planted out about the end of April, instead of transplanting them, the best plan would be to take cuttings every year. The following will be suitable: Alice Butcher (red, shaded orange), Blushing Bride (bright rosy-lilac), Flora (deep golden-yellow), Frederick Pelé (deep-crimson, tipped gold), George Wernig (primrose-yellow), Lyon (deep rosy-purple), Mme. Desgrange (white), Mrs. Hawkins (golden-yellow), Mrs. J. R. Pitcher (bluish-white), Pierce's Seedling (orange-yellow), Prémicé (golden-yellow), Mr. Wm. Pierce (red, changing to bronze-brown).—F.F.F.

GOOD LATE CHRYSANTHEMUMS.

MANY kinds are grown for late blooming, but the following are specially adapted for that purpose: Mrs. Marchant, a pure white, very fine incurved flower, very much like the much-praised Mrs. Alpheus Harly, but of a much better constitution, flowers very freely, and fine for exhibition. Ethel White, a splendid large flower, borne on long, strong foot-stalks, very free flowering, and very late; the only defect is that it shows the centre of the flower rather prominently. Snowflake, a very pure white, with quilled petals, of dwarf habit, and exceptionally late, at its best under ordinary treatment about Christmas. Snowdrop, a pure-white Pompon; its little bunches of pure-white little button flowers are very useful in decorations, very easily retarded until Christmas. Gloriosum, a lemon-coloured variety with quilled petals, extremely floriferous; a rather dwarf variety that makes splendid pot-plants, and excellent for cutting. Mrs. Jones, or Yellow Ethel, is the exact counterpart of White Ethel, except in colour; one of the best for long-stalked yellow flowers. Mrs. Hill, a fine, bronzy-yellow, very strong growing; makes splendid specimens for the conservatory. Cullingfordi, one of the best dark-crimsons in cultivation; a reflexed flower of great merit, very hardy, and lasts a long time when in flower. Mariano Lacroix, a beautiful pure-white fringed Japanese flower. It is not naturally so late as the preceding, but by the plan of cutting down in June, it is made to flower very late; in fact, it is one of the sorts most extensively grown for Christmas bloom by many market growers. Belle Paul, a tall-growing Japanese kind; a good late variety, with a pale-pink flower. Lily Lawrence, a broad-petalled, waxy flower, of great substance, pure-white; a naturally very late sort.

JAMES GROOM, Gosport.

CHRYSANTHEMUMS AFTER FLOWERING.

ALTHOUGH Chrysanthemums may be called hardy plants, a great percentage die off during the winter if left in the open ground. I do not think it is from actual frost, for here, in the South of England, they appear to suffer more than in places where they get very much more frost, and I always as a precaution keep a few plants under cover (even of the hardiest kinds) that I wish to preserve. Some kinds of Chrysanthemums throw up a great quantity of root suckers much earlier in the season than others, and these are comparatively safe; but it is these that are late in sending up young growth that require great care, for if left in the open ground, or if grown in pots, set out exposed to all weathers, there is considerable doubt as to whether they will throw up at all, for in mild open winters slugs are very active, and if they eat off two or three of these suckers, even before they appear above ground, there is a great chance of the plant going off altogether, and these sorts should be kept in a little warmth until some young growth is visible. When some cold frames are available, the put plants as soon as cut down should be set closely together in them, for even if only required for planting in the open ground they will repay the shelter of glass until the end of March, for when a stock of cuttings is secured many pitch the old plants away; but for outdoor flowering old stools are much the best if planted out with a good head of

growth on them, and allowed to grow right away without stopping, they make fine bushes, and flower earlier than plants grown from cuttings and pinched to induce a well furnished head of shoots. J. G., Gosport.

NOTES ON CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT EXHIBITIONS.—It is interesting to notice how greatly Chrysanthemum shows are changing. At one time every flower was either shown in the usual way on boards without leafage of any kind, and in a group, cramped together in a very solid way. Now we see a different style, and one that it is to be hoped will be further developed. The flowers are arranged in vases, one kind to each vase, and in one case, set off with the foliage of the Mahonia, the best of all for the Chrysanthemum, especially if of orange or bronzy shades. Twigs of leafy Beech or Elm are full of beauty when used with the flowers, and by no means less than when such orthodox foliage as that of the Maiden-hair is chosen. One danger noticed is to go too far, and crowd the flowers together in lumpy bunches. This is not what is wanted. Every flower should tell. Let it be seen, so that its individual beauty may give pleasure.

SINGLE VARIETY JANE.—This is one of the most beautiful of all Chrysanthemums, and if the cuttings are struck late, flowers are produced far into the winter. It requires very little disbudding and the objectionable plan one sees at shows of getting the single varieties very large deprives them of all characteristic beauty. They are far prettier when seen in graceful racemes on the shoots, and are of the purest white with numerous narrow florets.

CLASSES FOR JAPANESE KINDS.—The aspect of the Chrysanthemum, as far as shows are concerned, is gradually changing. We now get incurved and reflexed Japanese, in which the charming narrow and elegant florets are lost. Positively some of the newer kinds, like Lord Brooke, are as much incurved as Japanese, and the reflexed type is objectionable—the florets lumped together, short, and utterly devoid of grace and beauty. Then, again, not a few are very coarse-petalled, broad, ugly florets, fit neither for decoration nor to look at on the plant.

CHRYSANTHEMUM MR. JAS. CARTER.—Those who wish for a pretty little flower for table decoration or filling small vases should make a note of this. The flowers are composed of very narrow florets, and are not unlike a Centaurea. The colour very soft primrose-yellow. It is free, and when used with graceful Grasses or Fern is very pleasing. Writing of Chrysanthemums reminds me of the beauty of Lilian Bird, which may be described as one of the Catherine-wheel class, the florets narrow and shrimp-pink in colour. It is not necessary to disbud—at least, very little—as the disiro is to get sprays. The peculiar form of the flowers lends itself to decorations. F. P.

5241.—"Bush" Chrysanthemums.—Avalanche, Mlle. Lacroix, and Kynsford White are three of the best varieties to grow on the bush principle, where but one bud is left to each shoot. They are all white-flowered and fairly dwarf in growth. The first two are especially so. In addition to those already in stock the following six coloured sorts are suitable: Cul. W. B. Smith (oh! gold yellow, shaded terra-cotta), Excelsior (bright orange cerise), Ghiro du Roher (bright orange-amber, flushed crimson), Miss Watson (a lovely high bright yellow), Vivian Morel (deep-mauve), and Edwin Molyneux (crimson, gold reverse). Of the new sorts and those already in stock the following four will do in 7-inch pots: Avalanche, Source d'Or, Vivian Morel, and Bouquet Fait.—E. M.

5138.—Chrysanthemums in the open ground.—The following varieties will be found suitable for flowering in the open ground: Alice Butcher (red, shaded orange), Frederick Pelé (deep-crimson, tipped rose), George Wernig (primrose-yellow), Mrs. Hawkins (golden-yellow), Flora (deep golden-yellow), Mr. Wm. Pierce (red, changing to bronze-brown), Pierce's Seedling (orange-yellow), Prémicé (golden-yellow). Cuttings may be put in now and up to end of February; after they are struck grow them on in pots or boxes, and plant them out about the end of April. There are other varie-

ties, such as Roi de Précoce (rich dark-crimson), &c., which do very well in the south; but, as a rule, they will not flower here in one of the midland counties of Scotland. They are later than the ones mentioned above, and generally get destroyed by frosts ere they come into flower.—**FIFE.**

5227. — Propagating Chrysanthemums.—If no cuttings push from the old stool or root "T. D. L." must procure some from another source. Sometimes varieties are stalked about sending up suckers from the base. The only thing that can be done is to cut the stem down to within 2 feet of the soil, place the pot in a gentle heat, and syringe the stem twice daily, withholding water from the roots otherwise than simply giving sufficient to keep the soil moist.—**R. M.**

—The fault of stem cuttings is that they do not make growth free enough. They are so much disposed to make buds in their initial stage, which is a check to freedom of contract. Rather than depend entirely upon these for the stock of any particular variety, I should advise "Anxious Enquirer" to obtain some fresh cuttings from elsewhere, so as to make sure of having some healthy plants. At times stem cuttings do grow out of the frequency to bud, but they are not to be depended upon. If the old roots could be placed in a little warmth, and have their stems syringed twice daily, keeping the soil rather on the dry side, growth would be all the quicker in starting from the base.—**E. M.**

—Some varieties are naturally later than others, and all that can be done is to give them a little heat, and syringe the pots overhead frequently. If the cuttings do not appear in time, better purchase a few young plants. The stem-roots of some varieties make good cuttings and plants, but as a rule they form too many flower-buds, and do not grow freely. See also reply to 5227.—**H. C. R.**

—If the plants are healthy and well-grown very little difficulty ought to be experienced in obtaining cuttings, more or less, though some varieties are naturally much shyer than others. I have always found *K. Molieux* to produce plenty of cuttings, though they are often later than many other kinds. All you can do is to put the plants into a gentle heat, top-dress with rich soil, and syringe them overhead on fine days, and cuttings are almost sure to appear, sooner or later.—**H. C. R.**

—There is nothing for it but to wait patiently. Give the old plants a little heat. To get good cuttings early be content with fewer flowers. When a plant has exhausted its flowering freely, the cuttings of *E. Molieux* and some others start very slowly, and not infrequently come weak.—**K. H.**

5171.—Chrysanthemums for bush culture.—Presuming they are wanted for general purposes, the following twelve will suit. They will furnish blooms from October until January. Roi de Précoce (rich bright-crimson), Alexandre Dufour (rosy-purple), G. J. Quintus (pink-mauve), Mons. Wm. Holmes (rich-crimson, golden reverse), Margot (rose-chaumon), Lady Selborne (white), James Satter (blue-mauve), Sirene d'Or (bright-orange, shaded gold), President Hyde (bright-yellow), Mons. Bernard (bright purple-violet), L'Adorabile (dark canopy-yellow, shaded violet), Florence Frey (waxy-white).—**FIFE.**

IXORAS AND THEIR CULTURE.

For some reason or other ixoras are not cultivated nearly so much as they deserve to be. There is, I think, a popular notion that they are far more difficult to manage than they really are. If it is thought that bottom-heat is essential, that may be dispensed with, for I have grown them here very well without it, and seen others do the same. Bottom-heat is, I am aware, an accessory, but not indispensable. If the idea exists that growing ixoras means increased trouble with the mealy-bug, that also should be cast to the winds, for there are worse plants than the ixoras for this pest, the *Diphidania* to wit. As regards other insects, there is no extraordinary trouble, nor need any fears be apprehended from either the one or the other if a determined set be made against their increase. The best time to commence the culture of ixoras is in the spring, with small plants well furnished in nothing larger than 8-inch or 7-inch pots. The best season for propagating is from now onwards to the end of March—at least, I find this to be the time when I can succeed best. The additional warmth all through the winter in the pipes gives a reliable bottom-heat for striking. I prefer to take cuttings of the current year's growth, and when it is semi-hardened being preferable to that fully

matured. The cuttings should be placed firmly and singly in 2½-inch pots. If the room be short, the cuttings will be found to strike very well in water, being potted when rooted. The former plan is, however, preferable, as another small shift can be given without any check at all.

THE CUTTINGS should not be allowed to droop by exposure; this they will not do in a close pit with warmth. For the first year the aim should be to secure a good well-furnished base rather than attempting to lower the young plants. By a few stoppings a good groundwork will be formed; the shoots should also be drawn outwards in a semi-horizontal manner. This will encourage back breaks. For whatever purpose the plants are intended, the foregoing plan is a good one, as bushy plants are in any case the best. After potting from the 3-inch pots must be regulated according to the progress that is being made. When this is satisfactory, the plants should be good bushy ones in 6-inch pots in twelve months from the time of striking. If struck in the autumn or winter and kept growing, they would be fit for 4½-inch pots by April and for 6-inch pots by July, in which pots I would prefer to winter them, giving the next shift about February. The following summer they would give a good crop of flower—a dozen heads or trusses to a plant. They may be grown very well as decorative plants in smaller pots. I have had them thus in 4½-inch and 6-inch pots with six and eight or more trusses, thus making very attractive plants whilst in flower. An excellent plan is to continue striking a few plants fresh every year, so that a successive supply is always on hand. If it is wished to grow on the plants to half or

SPECIMEN SIZE, I would not let them flower the two first seasons at all, making the chief object that of growth entirely. As to soil, there is a difference of opinion. For my own part, I prefer the best peat I can get, full of fibre and of lasting character, such as one would choose for New Holland plants or Cape Heath. To this I would only add silver sand in a liberal manner. If the peat is not first-rate, then a good addition is some nutty charcoal or cracks broken up finely. Good leaf-soil from the Beech or Oak is very good, but if used to any extent is not easily made so firm in the pots as peat; with this I would mix good fibrous yellow loam; with this I would make a very good mixture with sand. I have seen *I. coccinea superba* thriving very well in nearly all loam, but the foliage is not usually so deep in colour as when in peat, nor do I think the plants would last so long in good condition. Firm potting I firmly believe in; I consider it one of the essentials to success, for if a plant is to last well it must be potted well. When loosely potted, the stem in time will become loose and the soil far too porous. Overpotting is not desirable. When the plants are pot-bound and showing for flower, some weak liquid-manure will assist them not, however, too frequently. In order to flower plants at any given future time, the treatment must be regulated accordingly. If they are needed in bloom in May or earlier, the growth must in a large measure have been made the previous summer and autumn; then after a short spring growth they will thus set for flower. If I remember rightly, Mr. Baines kept his plants of *I. coccinea* growing in a brisk temperature all the winter, showing them grandly in May. For

LATER FLOWERING, early spring pruning followed by fresh breaks will be the best plan to pursue. In some cases, as when growing on young specimens, merely topping the shoots would be all that is necessary. The other plants that would flower in May would, as far as any pruning is concerned, have to receive attention the previous summer rather late. If plants are needed in flower in August or September for any given purpose, they should on an average, taking one sort with another, be stopped all over at one time about sixteen weeks before they are wanted in bloom. Thus if stopped at the middle of May, they would flower about the middle of September, and so on. In any case the stopping is a safe plan to adopt if autumn flowering is the main object desired. As regards

TEMPERATURES, I find that so long as 50 degs. is the minimum at night during the winter,

preferring, however, that it should be nearer 65 degs. than 60 degs., I can grow them most satisfactorily. By the end of February I would aim at 70 degs. at night in fair weather; less when severely cold, say 65 degs. By the end of March or the early part of April, 70 degs. at night ought to be maintained. The day temperatures should range from 10 degs. to 15 degs. higher according to the weather. Higher than this even will do no harm; even 90 degs. and 95 degs. at closing time in the summer is only congenial to them, especially the Japanese section, under which most of them are included. The higher temperatures cannot always be maintained in a mixed house of plants without some detriment to other plants. Where, however, all are calculated to do well under it, rapid progress can be made. In my own case I am growing them in a pit formerly used for Pines with a fair command of heat, to maintain 60 degs. or 65 degs. being comparatively easy in the winter, whilst in the growing season the day temperature would more often than not touch 80 degs. at closing time with about 70 degs. at night. I have already alluded to bottom-heat. In the spring when starting the plants into fresh growth it accelerates root-action, and thus assists the top growth.

YOUNG PLANTS also can be grown in more speedily when plunged in a brisk heat or temperature of 80 degs. or 85 degs., which is high enough in any case. But rather than have the plants plunged in any material which has a tendency to become soddened, I would infinitely prefer to let them stand over rather than in fermenting material. I have grown them in bottom-heat and out of it, and have been satisfied with the results in both instances. In the former, however, the plants will not take nearly so much water; in fact, as the season progresses it must be given with some considerable caution. In the latter manner more water can be given at the roots with safety. Taken all ways, I think bottom-heat for starting into growth and hastening on young stock is the best, but as growth becomes well advanced I would prefer to dispense with it. The syringe should be freely plied at all times; this, whilst it assists the joints greatly in making their growth (a humid atmosphere being most congenial), at the same time softens the jarring material. By a free use of the syringe also the insects to which they are subject can be better kept in subjection.

CLEANLINESS from all insects is most essential, mealy-bug, thrips, scale, and fly all coming within the category. We can control all the three last-named by the syringe, the sponge, and occasional fumigations. The *Ixoras*, being evergreen plants, should not be kept too dry during the winter, even if no growth is in progress; sufficient water must be given to keep the foliage fresh. I well remember an old plant grower who was fond of *Ixoras*, but who erred in keeping the plants too dry in the winter; hence thrips were troublesome, whilst some of the wood would die and the plants be considerably weakened, fresh growth coming away weakly in the spring. Specimens do not, of course, suffer so soon as smaller plants, by reason of the larger amount of soil, unless they happen to be pot-bound. As to names, if I were limited to half-a-dozen kinds, I would grow *I. coccinea superba*, *I. Fraseri*, *I. Prince of Orange*, *I. Westi*, *I. Williamsi*, and *I. Pilgrimi*, with *I. macrophylla* as a special variety for specimens. **H.**

Nurses for plantations.—The use of nurses in plantations is a subject deserving of notice. How seldom do we find these planted sufficiently thick or of adequate strength to give the necessary shelter to the main crop! The extent to which they should be used must depend upon the exposure. Where this is great they may be filled into within from 30 inches to 50 inches of the standards and of each other. Upon more sheltered sites they may be from 4 feet to 5 feet apart, and when thinned out, they will have attained useful sizes. The Mountain Ash is second only to the Larch for use in bleak situations, and the Spruce will afford a better shelter upon a less space than the Scotch Pine. The Scotch Spruce, Norway Maple, Pinaster, and the Elder are very serviceable near the standards. **A. I.**

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 21, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by adopting, as far as their knowledge and observation permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that general answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5213.—Potatoes for show.—Will someone kindly name the best two Potatoes, Round and Kidney, for show?—CRIBBO.

5211.—Showy Hibiscus.—Will someone give me five names of two or three of the most showy Hibiscus, "Althea frutescens"?—PAGES.

5215.—Treatment of a Hydrangea.—I have a plant of this, which flourished well. How shall I prune it, as I am told it should be cut down?—P. J.

5212.—Veronica in pots.—I wish to grow plants of Veronica in pots. Will someone please describe their culture, and to they require more than the ordinary greenhouse temperature?—F. J.

5217.—Rock plants.—I am just now building a rough wall of large stones at the end of a lawn, and shall feel greatly obliged if anyone would give me the names of a variety of rock plants suitable for planting between the stones?—H. S.

5238.—Pea and Bean for show.—Which is the best variety of Pea and the best variety of Bean for exhibition, and when should they be planted, and how should they be grown, to have them ready for showing in August?—H. S.

5240.—Growing Cucumbers and Melons.—I should like to know if a large area in large pots as well as by putting the soil loose on the slugs in a small stove, as I think it would take less room?—A CORSTANT MELON, Birmingham.

5252.—Hydrangeas in pots.—Will someone kindly tell me the proper treatment for Hydrangea-plants in pots? I have some that have been at rest, and all their leaves are off. I would like to have them in flower in August or September next.—JANE.

5251.—Open-air Chrysanthemums.—Will someone kindly recommend the best Chrysanthemums, of various colours, most suitable for cultivation in the open ground, six for each of the autumn months of September, November, and December?—HEAT.

5253.—Kidney Potato for show.—I shall be very thankful if someone will give me the name of the best Kidney Potato for show, also the name of the best round variety for the same purpose, and how ought they to be grown to get them in condition for showing by the last week in July?—H. S.

5255.—Pruning Vines.—Will someone kindly tell me the best mode of pruning Vines, having several in a house, but have not pruned any before now? Should they be cut close in, or one or two of the spurs left off? Full information as to cutting, and when is the proper time, will be obliged?—DANIEL OF GRAPES.

5254.—Cutting back a Magnolia.—I should be pleased to know how much, and when, I may cut a Magnolia back? It is nearly 30 feet high, and 3 feet in width, and grows very strongly, and is getting too large for the space. Can I strike cuttings, or how is it best increased, as I wish to get a small plant or two?—A READER, Hoveley.

5257.—Auriculas in a garden.—I have just taken charge of a garden where there are a lot of Auriculas. They were nearly covered with leaves that the wind had blown among them. I have cleared them all off. They now have a very queer look, with long legs and very small tops. They had slumped off a great deal. Can I do anything more to help them now, or must I wait till winter is over?—FANNY.

5256.—Mistletoe.—I had very much pleasure reading the article recently in HANDBOOK on Mistletoe. This is a plant very little known in this country except when it comes to the Christmas markets (very abroad). I should like to grow some, and would be very much obliged to any of your Liverpool-shire readers who would supply me with some ripe berries in their season? H. GIBSON, Ballyvaughan, Belfast.

5257.—Cabbage for show.—Will someone kindly tell me which is the best variety of Cabbage (both red and white) for show purposes, and when should the seed be sown, and how should they be treated to have them ready for exhibiting in August? Also which is the best variety of Cauliflower for the same purpose, and when should the seed be sown, and how ought they to be grown to have them fit for getting at the same time?—H. H.

5258.—Solanan capitestrum.—Last spring I sowed some seedlings of these in my greenhouse. When the plants were large enough I planted them outside in a prepared bed. They grew strong and flowered freely, but did not set any berries, although they were well watered. I have now cut them down to within 4 inches or 5 inches in the pots, and they are starting again. How shall I treat them in order to have them well fruited next season?—T. J.

5259.—Poplars.—Will someone kindly let me know if Poplar-trees can be topped without injuring them, and if it does not increase their root-growth, and consequently take still more goodness out of the soil; also as to the best time for the operation? The trees are about 40 feet high, and about 10 feet apart, and are pressing against the garden fence. I have been told that topping would increase this, and at the same time make them more bushy.—POPULUS.

5262.—Best Carnations.—On page 535 (December 21st) there is given a list of about three dozen of the best Border Carnations. I should be much obliged if P. H., or anyone else who has grown them, would kindly say which of these they have proved to be "non-bursters," as so many of the border Carnations here the fatal characteristic of splitting the petals, rendering them almost useless? Even a small list of non-bursters would be of great service.—E. C. PARKS.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

BEEES.

SEASONABLE NOTES.

About this time Bees require but little attention beyond seeing that the floor-boards and entrances of hives are kept clear, to ensure ventilation, and carefully guarding against dampness within the hive.

PACKING HIVES FOR TRAVELLING.—Excepting during a hard frost colonies of Bees may now be moved long distances with safety. Care is, however, necessary in packing, so as to avoid the breaking away and falling of the combs, such a calamity being almost a certain restriction to the Bees. The secret of success in moving colonies of Bees is the admission of plenty of air into the hives. The excitement and emigration of Bees on being removed greatly increases the internal heat of the hive. In preparing straw hives for travelling, they should be inverted, and placed in cheese-boxes, having a nut lay at the bottom to prevent jarring. Before inverting the hive a little smoke should be blown into the entrance to drive the Bees up amongst the combs. The hives should then be turned up, and coarse sack or canvas tied over to confine the Bees; they thus get abundance of air, and in that respect travel safely. To prevent the combs breaking down, a sharp-pointed stick should be passed through the sides of the hive, so as to pierce each comb. This should be done a few days before removal. The Bees will fasten the combs to the stick, and so greatly increase their firmness. Another way to keep the combs steady and firm is to push wedges of crumpled paper between the combs. These paper wedges, being elastic, prevent the jarring of the combs. In cool weather there is not so much risk of combs falling, and the inverting of the hive is not so necessary. Hives of all, tough comb, with sticks passed through them, may be safely moved by first nailing them to their floor boards, covering the entrance and crown-hole with perforated zinc, and tying them with cord to their boards. In moving frame hives the frames should be fixed quite firmly by notched strips of wood nailed to the floor boards, and placed at each end of the frames. The Bees should be confined to the hive by perforated zinc nailed over the entrance, and also over the tops of the frames, in place of the quilt, the perforated zinc being so placed as to allow the Bees to pass freely between it and the tops of the frames. In this way they get more air than they can if the zinc be fixed close to the tops of the frames, and some of the weight of the Bees is thus taken off the combs. As soon as the hives arrive at their destination they should be placed where they are to stand, the zinc on their tops removed, the quilts and rafts put on, and the entrances opened.

BEE'S ENEMIES.—The chief enemies to guard against at this season are mice and birds. The following quaint remarks on the subject were made nearly two hundred years ago: "The

good Bee, as other good people, hath many bad enemies, which she herself cannot overcome without the assistance of man, for whom she labours, and, therefore, the wise Bee-man will take care to destroy the enemies of his friend, the Bee, whose enemies are: The mouse (whether he be of the field or house) is a dangerous enemy, for if he gets into the hive he pulls down the combs, makes havoc of the honey, and so starves the Bees. Some gnaw a hole through the top of the hive; some keep their old homes, and come to the hive only for food; and some make their abode between the huckle and the hive. To prevent this take care that your hives be well and closely wrought, for if the straw be loose and soft they will the easier make their way through the hive. The Woodpecker and Sparrow are both enemies to the Bees; the Woodpecker with his long, round tongue draweth out the honey, but he does more mischief to wood Bees than to those of the garden; the Sparrow doth devour the Bee from the time of the first heading till the Wheat be kernel. The Titmouse is another enemy, of which there are three sorts. The Great Titmouse, from his black head and breast, is the worst enemy of the Bees. He always watches at the hive for the coming and going out of the Bees. He will stand at the door, and there never leave knocking till one cometh to see who is there, and then, suddenly catching her, away he lies with her; and when he hath eaten her he lies back for more. Eight or nine will scarce serve his turn at once. If the door be shut that none can come out, he labours to remove the bar. If that be too heavy, he falls to undermining the door for a new way; and when these devices cannot get them out, some have the skill to break the slatted walls of the hives above over against the place where they lie, and there they are sure to have their purpose. The little Russet Titmouse in the winter feedeth only on dead Bees, but in the spring he will take part with the great ones. The little Green Titmouse can only be accused of eating some few dead Bees, and that only in some hungry time." G.

5261.—Management of Bees.—Having casually bought four hives of Bees this week at a sale, will some kind friend tell me what I am to do with them through the winter as to the management, &c.? I may mention two of the hives are somewhat heavier than the others. Do they want feeding, and what, and how to give? What is the best position? Should I be due south? I may mention the hives are straw, with a small aperture on top with a movable cap to allow another hive to be placed over if necessary. Any information as to the above, and also what are the best hives for use, will greatly oblige?—YOUNG BUNNEN.

POULTRY AND RABBITS.

REARING DUCKS.

If young Ducks get their liberty they will wander far and wide in search of slugs, worms, &c., and cause no slight anxiety to their owner; or, if they once obtain access to water, which it is desirable to keep beyond their reach, they will never rest satisfied unless they can enter the pool or stream whenever they choose. It is this wandering propensity on the part of Ducklings which causes so many of them to fall victims to rats and other enemies. Many a promising brood has been entirely swept away by rats. I have known the latter to enter a coop at night and kill the whole hatch. They will also lie in wait on the sides of a ditch and swoop down upon the ducklings as they are revelling in the mud below. Some years since, out of a lot of seventy Ducklings, I did not get forty fit for market, nearly the whole of the remainder being captured by the rats in the manner just described. The reader, then, will understand that there are situations, such as near the banks of a stream, or in the neighbourhood of old barns and rick-yards, where the Duck-raiser must be very careful or his profitable success will be few and far between. It is not enough to hatch good broods—they must be reared. I, therefore, advise anyone who contemplates Duck-breeding to take a good look round before he commences operations, and, if the visits of rats are feared, let him adopt chicken-rearing instead. As Ducks consume

A LARGE QUANTITY OF FOOD, it is necessary, if profit be the end aimed at, to hatch the Ducklings as early in the season as possible, so that the full benefit of the high prices which prevail in the spring may be obtained. The birds, too,

must be kept improving from the time they are hatched until they are ready for the spit. Large numbers of Ducklings are, I know, hatched during the summer and remain about the yards for some months, and then are fastened up for two or three weeks to be fattened. It is impossible for much profit to be got out of such birds, and too often, I fear, they are reared at a loss. As in the time required for getting Ducklings ready for market I may describe a case which occurred several years since in a southern county. Early in the spring a brood of Ducklings was hatched at a farmhouse. Among the servants employed there was a young fellow who was himself the son of a farmer. When the Ducklings were taken from the nest he offered to take charge of them, and pledged himself, on condition that he could use as much meal as he wanted, to get the birds ready for market at eight weeks old. His offer was accepted. He at once placed the hen in a coop near a small pool, and there the Ducklings remained until they were sold. Bread-crumbs, hard-boiled eggs, and curds were used for a few days, after which nothing but Barley-meal was given, and on this the Ducklings were made fit for the table by the time stated. Such cases are perhaps exceptional, especially with Ducks kept by ordinary farmers. Still, it is surprising what can be done in a short time if constant attention be given. It is in something the same way that fowl keepers to go to work. Supposing the eggs used for sitting are laid about the same time, and are fresh, the whole should hatch on the twenty-eighth day within a few hours of each other. If the Ducklings are hatched by a hen, as is probably the case, I should remove them from the nest when they are about twelve hours old. Nothing will be gained by delay unless some of the Ducklings are not thoroughly dry. Their first meal should consist of hard-boiled egg and bread-crumbs. Very little will be eaten for a few days, but as soon as the Ducklings begin to pick, oatmeal may be given; and this may be followed by Barley-meal and sharps mixed together. The whole of the meals should be mixed into a stiff dough, which will break when thrown in the ground. As regards water, use as little as possible. According to my experience, the more water the Ducklings have the longer they are in getting fit for the market. They thrive best when kept on a dry grass run. No special fattening is necessary if the birds are well fed throughout, but scraps of meat, liver, Potatoes, &c., may be mixed with the meal, and are all good foods when this used. The Aylesbury breeders, who send an enormous number of early Ducklings to London every year, use boiled meat and greaves in addition to the meal. Their birds are speedily made fit, and fetch very high prices. After the Green Peas are done with Ducklings decline in price, and, in my opinion, pay but little, if anything, for rearing.

Seasonable notes.—The last month of 1893 having run its course, it is time for the poultry breeder to look forward, and begin to make arrangements for the next hatching season. If fresh blood be wanted, cocks or cockerels should be purchased without delay, so that the breeding-pens may be at once made up. This is particularly necessary where very early chickens are required for exhibition purposes. Even among ordinary stock kept to supply eggs and fowls for home consumption the same foresight is needful, for if eggs are to be forthcoming next November and December pullets must be hatched in March and April. The birds which are now laying should be well fed, and kept warm at night; attention should, therefore, be given to the fowl-house. All birds not wanted, whether cockerels or pullets, should be killed or sold at once, so as to get the chicken-runs in good condition for the spring broods. If the cockerels run with the ordinary stock there is the more reason for parting with them, for they worry the pullets, and lose flesh themselves.—D.

5262.—**Poultry keeping.**—Will someone kindly tell me whether it is injurious for hens to be kept in the dark when sitting, and also which is the best food for laying hens at this season of the year? My fowls are left to go where they like in a field, but at night one of the hens refuses to come back to the poultry-house. What is the remedy for this, as the hen in question is then exposed to the cold night air?—KIRRY DENNIS.

EVERYONE WHO HAS A GARDEN GREENHOUSE, OR WINDOW HURDLE SHOULD READ A PAMPHLET, POST FREE.
HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. WITTE, F.R.S., F.C.S. Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. W. M. COOPER'S SEVENTH ANNUAL CLEARANCE SALE

RELIABLE BARAINS.

NOT SECOND-HAND GOODS.

Office: 755, OLD KENT ROAD, LONDON, S.E.

Works (the Largest Steam Horticultural): 747 to 755, OLD KENT ROAD, LONDON, S.E.

Show Ground: DEVONSHIRE GROVE (Adjoining).

Being the end of the Season, I am again induced to offer my stock on hand at ridiculously Low Prices, to make room for my SPRING STOCK, for SIX WEEKS ONLY, COMMENCING DECEMBER 4th. **LAST DAY OF SALE, SATURDAY, JANUARY 13th, 1894.**

CONDITIONS OF SALE.—Goods are offered subject to being on hand on receipt of reply. Cash to accompany all orders, and prices to be strictly net. All orders will be executed in rotation, and carefully packed and put on rail, except those otherwise stated. P.O.O. payable at 794, Old Kent Road; Cheques crossed "L. and S. W. Bank."

SPECIAL NOTICE.

I respectfully beg to inform all readers of this paper that my Revised Price List, elegantly bound in cloth, gold lettered front, consisting of 400 pages with about 1,200 illustrations, is Now Ready. I shall have much pleasure in forwarding, upon receipt of One Shilling, a Copy, post free, of one of the most Complete and Descriptive Lists of Horticultural and Garden Requisites, and also Poultry Appliances, extant.

GREENHOUSE DEPARTMENT.

THE AMATEUR FORGING HOUSE. TENANT'S FIXTURE (SPAN-ROOF).

These Houses are offered at an exceedingly low rate, and should be readily approved by both amateur and professional gardeners, as brick work, which is very expensive to a small house, is entirely dispensed with.

The utility of such a house for forcing or cultivating cucumbers, tomatoes, melons, &c., will be perceived at a glance, it being a structure constantly in request but almost hitherto unknown.

Sp. of Glass.—Framework substantially constructed of red deal in the whole of sills, and 2 ft. 6 in. of end, boarded with well-seasoned tongued and grooved matchboards. Half-glass door, complete with rim lock and brass fittings, in one end; glass 15 in. throughout, English cut. Ventilators supplied according to size of house, and sashes raised for opening same; stages for plants each side of house, all woodwork painted one coat of good oil paint, and the whole structure securely packed and placed on rail.

Lot.	Length.	Width.	Height.	Usual Price.	Sale Price.
1 to 7	7 ft.	5 ft.	7 ft.	£2 10 0	£2 0 0
8 to 10	8 ft.	5 ft.	7 ft.	3 0 0	2 5 0
11 to 13	9 ft.	6 ft.	7 ft.	4 0 0	3 10 0
13 to 23	10 ft.	7 ft.	7 ft. 6 in.	4 10 0	3 10 0
23 to 29	12 ft.	8 ft.	8 ft.	5 10 0	3 15 0
30 to 41	15 ft.	10 ft.	8 ft. 6 in.	7 15 0	5 10 0
42 to 49	20 ft.	10 ft.	9 ft.	10 15 0	7 10 0

52 to 54	30 ft.	10 ft.	9 ft.	27 0 0	20 0 0
55 to 56	100 ft.	10 ft.	9 ft.	45 0 0	25 0 0

SPAN-ROOF VILLA CONSERVATORIES.

Adaptable for the lawn of a villa residence, being well and substantially built, constructed of the best materials, and artistically finished with diagonal panes and large boards.

The framework is composed of 2 in. by 3 in. red deal, the lower part doubly-lined, with tongued and grooved matchboards, and the roof properly fitted with sashes, which facilitates raising or removing of same without disturbing glass.

The houses are fitted with a half-glass door, complete with rim lock, brass fittings and key, and is supplied with lattice staging for each side, footpath the entire length; gutters, downpipes, suitable ventilators, and necessary ironwork for opening same.

All woodwork painted two coats of good oil paint, glass cut to sizes, and all parts securely packed on rail. Prices.

21 oz. for Roof 5 per cent. extra.

"AMATEUR" SPAN-ROOF AND LEAN-TO GREENHOUSES. TENANT'S FIXTURES.

Made especially for Amateurs at a nominal figure, thereby enabling within reach of those who require a strong but inexpensive structure, and being constructed in complete sections, are erectible by any handy man or gardener in a few hours. Framework is substantially constructed of red deal, the lower part being fitted in with well-seasoned tongued and grooved matchboards. The house is fitted with door complete, with rim lock and brass furniture, painted one coat of good oil colour, supplied with all necessary ironwork and sashes for each side and good 15 oz. glass through out. All parts securely packed and put on rail. Prices:

GREENHOUSE PLANTS FROM SEEDS.

There are several very useful greenhouse and half-hardy plants which do not come to perfection during the first season unless sown early in the year. The following may be named among others: Begonias, Streptocarpuses, Lobelias, Petunias, Gloxinias, Tarenias, Verbenas, and Amryllids. Unless sown early we do not get these in their full beauty until the season is waning. Too much stress cannot be laid upon the benefits arising from the use of a good strain, whatever the subject may be which we are wishing to propagate. Nor can I call too much attention to the value of thin sowings. When sown thickly the resulting seedlings crowd one another and often damp off a short time before getting sufficiently large to handle. It is a good plan to make more than one sowing, or, at any rate, to divide the seed and notice how the first lot germinates. If you cannot afford to pay the price of good seeds from the choicer strains, try and persuade a friend to go halves with you, and so secure a small quantity of the best. A very little seed will produce a large quantity of plants if treated carefully. Inferior strains need quite as much attention and labour, and do not give nearly so much satisfaction as the results from a small number raised from a choice and carefully-selected stock. Most of the subjects I have named have very minute seeds, and much care will be needed when sowing them. Go over your ground more than once, scattering the seeds very thinly indeed. You will thus secure a far more even sowing. Lobelia, Gloxinias, Begonias, Petunias, and seeds of similar minuteness will be better if not covered with soil. Others, like Verbenas, Mignonette, &c., will need a very slight covering, more or less, according to size. It is a fairly good rule to cover them to a depth of about twice the diameter of the seeds. Those not covered must be kept dark until germinated. This is a great aid, is safer, and avoids the sudden and fatal drying up of the very young plant when a few minutes' sun or a little neglect in watering occurs. In short, even the larger seeds are benefited by being covered over with some darkening material, and then gradually exposed to light after germination is complete. I always place a sheet of glass over such fine seeds as Begonias and Gloxinias, and then darken this. Very gentle bottom-heat will aid, and is necessary for these when sowing early. You cannot supply too much light to the young plants as soon as roots are penetrating into the soil freely, and it is a good plan to place them close to the glass, thus ensuring a sturdy growth. Half of the failures with seedlings really occur in their early stages; either from being crowded, or drawn up too quickly. Amateurs are also too prone to supply a rich compost. The tender little seedlings cannot assimilate strong food; we must wait until they are a trifle larger before affording them rich composts. Almost all seeds like the following mixture: Sand, loam, and leaf-mould in about equal proportions. See that good drainage is provided, and pay considerable attention to the

the pots or pans are filled. We must remember that it will be necessary to lift the seedlings directly they can be handled with facility; therefore, coarse and uneven soil will not be suitable. My own plan is to use a couple of different sized sieves or riddles. The roughest one are placed in the bottom of the pans, and the roughest from the smaller sieve placed upon that, finishing off with a well-mixed and uniform compost. When lifting the seedlings and we have no fear of breaking the roots—in fact, they come away with little balls, and move without much appreciable check, I have had greenhouse subjects more particularly in mind while penning these notes, but it will pay well to follow the list of them when sowing Asters, Stocks, or any other seeds. P. U.

CHRYSANTHEMUMS.

Naturally-grown Chrysanthemums.—No doubt there are different ways of defining a naturally-grown Chrysanthemum plant, but what I especially allude to now are those plants which are allowed to grow unchecked without topping the shoots or in any way limiting their number. Such plants as these are seen at the shows in Belgium, and very effective they are, being as suitable for the home decoration of the conservatory as they are for forming groups at an exhibition. The height of such plants varies according to the variety, ranging from 3 feet to 6 feet. I do not remember to have ever seen plants of this class at an English show, where I am sure they would be welcome if of the same quality as those grown in Belgium. The only point about these that interferes with their strict natural growth is that the flowers are limited to one on a shoot, the number of blooms to each plant varying from thirty to sixty. Varieties like Elaine, Val d'Audorré, or, indeed, any of the reflexed Japanese, are the most suitable for this form of culture, they being, as a rule, of dwarf and medium height, generally with stout stems. The blooms are also self-supporting, having stout peduncles. Pots 9 inches and 10 inches in diameter are large enough for any variety. Cuttings should be rooted early in the year, the plants shifted into larger pots as required, and given abundance of room for a full development of the foliage and shoots. When the plants make their first natural break in April or May, according to the variety, instead of restricting their number to three, as in the orthodox method, where three large blooms are required, the whole of the shoots except the very weakest at the bottom are allowed to grow. Again, in August, when the second break takes place, the number is again increased. Each shoot is then allowed to carry one bloom, which will be a terminal one, or if more are required, the buds need not be removed, as many will cluster at the tips of the shoots. If fairly large blooms are wished for, one on each will be quite enough. One stout stake to each plant will suffice as a support for all the stems if these be loosely secured, it being possible to tie them that the heads will not

have a formal appearance. It is most essential that the foliage be preserved in good condition, as upon this much of the appearance of such plants depends.—E.

25th. — Open Air Chrysanthemums.—I have recently dealt with this subject, but give again a brief selection. For September six good varieties would be, first of all, Mme. Desgrange and its sports (but commence with the type, a very free and beautiful flower), M. Gustavo Gruenerwald (delicate pink, passing to almost white, a new and very charming kind, which has not been inaptly called a pink Mme. Desgrange), La Vierge (pure white, dwarf, and very free, the plants quite a mound of bloom), Alice Butcher (red, shaded orange), Golden Shah (yellow, a hybrid Pompon kind), Lyon (deep rose-purple), Mme. la Comtesse Foncher de Carcil (orange-red, a very free and pleasing variety), and Wm. Holmes (crimson). These I have seen all succeeding well in the open, as I have made special note of kinds for this purpose during recent years. November and December may be grouped together, as few kinds bloom naturally in December, and these are really November varieties. Select, first of all, Cottage Pink, a kind one sees largely grown in cottage gardens, the flowers light-purplish in colour, and produced with great freedom, a sturdy, vigorous kind, resisting well rains and fogs even; Jardin des Plantes (yellow, a bright and showy flower), Jules Lagrevire (deep purple-rose), Mrs. Rundle, the old Triomphe du Nord, and Golden Beverley are of note. Not many kinds really succeed well late in the year, and then the plants must be grown always in the open. The highly-fet plants in greenhouses soon suffer when exposed to the weather.—C. T.

— Without some protection Chrysanthemums cannot be depended upon to flower outdoors during the months of November and December. Last season proved this fact very conclusively, the severe frost which occurred on the night of November 17th just about crippled the flowers for the year. During some seasons the plants go on flowering quite up to the second week in December; but, of course, these are exceptions. Undoubtedly a wall with a southern aspect affords the greatest security from frost for plants wholly grown without glass. Where nothing but the open border is depended upon, the best plan is to select early-flowering varieties, and obtain from these a full crop of flowers. It is almost useless to attempt to grow the incurved section, the natural formation of their florets is all against their withstanding adverse weather. The incurved petals are natural receptacles for the collecting of moisture, and in this state the blooms are more easily injured by frost than when they are comparatively dry. Varieties belonging to this Reflexed section are the most suitable, the natural imbricated form of their petals prevents moisture collecting amongst them. The following varieties are suitable for the purpose indicated: Mme. C. Desgrange (white, with cream centre when opening), G. Wernig (primrose-yellow), Mrs. Hawkins (bright yellow), Leon Lassali (white, primrose centre while expanding), Blushing Bride (bright rose-like, fading to blush), Alice

Butcher (red, shaded orange), Flora (deep golden yellow), Lady FitzWygram (white, dwarf habit), Mrs. Cullingford (white), President (maroon), Empress of China (silvery pink), Gullien Christine (golden buff), Temple of Solomon (yellow), La Vierge (creamy white), Elsie (canary yellow), M. E. Pynaert Van Geert (deep yellow, flushed red), Pierce's Seedling (bronze, passing to yellow), Procoëtis (yellow), Wm. Holmes (red, tipped gold), Alexander Dufour (rosy purple), M. Gustave Grunewald (soft pink, passing to bluish white).—E. M.

GARDEN WORK.

Conservatory.

It is a very great advantage, both for the welfare of the plants and also for effective arrangement, to change the position of all the plants occasionally, and as far as possible group the various families together. A Cyclamen or a Dendrobium is not much alone, but a group of other of the plants named, set off with appropriate foliage, attracts attention at once, and graceful foliage is as necessary as flowers. Most of the Acacias have pretty foliage; Camellias have good foliage, though there is no grace or elegance in *Hamamelis-leucoc.* There is something striking about healthy, well-grown Camellias; but they are under a cloud at present; they will come back in favour in the future. The places of the Camellias and Oranges have been taken by Palms and Tree-Ferns. How very pretty and fragrant a good-sized group of *Freesia* are now mixed with a few Maiden-hair Ferns in 5-inch pots! *Camellias* have flowered well, both trained on the wall and also as bushes in the border, and a good-sized plant makes a grand show for several weeks. I have been cutting a few Tea-Roses, including an old *Marshall Niel* or two, the flowers being much deeper in colour than is seen in spring. Tea-Roses planted in a large, lofty house, where there is room to strike out, are never altogether without flowers; and I have noticed they grow and flower freely in the beds prepared for Camellias, in which a good deal of peat and leaf-mould has been mixed with the loam, the latter being very fertile—in fact, only the best admitted from the conservatory for this special purpose. In making new beds in conservatory, if leaf-mould is used it is necessary to pick out all fragments of stick; the best way is to pass the leaf-mould through an 1/2-inch sieve to take out sticks and stones, if it contains any. Stones may be harmless, but bits of wood frequently introduce a fungus among the roots which often does serious harm. It takes some time to work plants round in condition again after having the roots attacked by fungus in the border. To get rid of fungus in a border, thoroughly saturate the soil with weak root-water. More than one or two waterings will be necessary.

Forcing-house.

It is a mistake to use too much heat, especially at night, during the very short days; 65 degs. at night will be high enough for all kinds of forcing. Berries should be plunged in the hot bed as soon as the buds have made some roots; without the bottom-heat the flowers will not be so fine or quite so fragrant, propagating may begin as soon as cuttings of the various plants required can be had. Cuttings of the young shoots of Tree Carnations will not now in almost sheer sand be kept quite moist, but must be potted off as soon as rooted. Keep young Chrysanthemums, Melons, and Tomatoes steadily moving on. The bunches of Grapes on the Vines must be reduced in number, leaving about six bunches on a strong Vine. Thin the berries as soon as it can be seen which are taking the lead. Vines in bloom must have a little assistance in setting; shaking the rod or drawing the hand gently down the bunches will disperse the pollen. Do not give stimulants till the berries are set and swelling; liquid may be given to Roses in pots as soon as the blossom-buds are visible. If the syringe is used freely there will not be much trouble with insects. Dust the first sprouts of milk with black sulphur. Cut down *Bursera*, which have done blooming, and keep rather dry till the buds break. Young shoots make good cuttings.

Tomato-house.

Everything in the house must be perfectly sweet and clean. If Tomatoes have been grown in the house before, sulphur fumes, raised by heating a plate of iron red-hot and scattering a handful of sulphur over it, will destroy all fungus spores; but the house should contain no plants when sulphur is burnt, as the fumes will destroy every green leaf and shoot. If the house is intended to be forced, the border should be trenched up and got ready for planting. All Tomato-houses should be heated; the crop will pay for it, as when the season advances the price soon drops. Tomatoes have been grown several years in the same beds without changing the soil, but after the third year some of the soil should be changed, if possible, though a good dressing of soot, lime, and salt has a purifying and invigorating effect. When boxes are used to set the plants the soil will be changed annually.

Orchard-house.

If not already done, the trees in pots should all be returned to the house and have the necessary pruning and re-heating. Any trees in small pots may be shifted into larger ones, but such work should be done in autumn. More trees may be started in the house than there will be room for; it is always some of the late Plums may be plunged outside to ripen fruit end of June.

Mushroom-house.

Continue to make up new beds to replace those which are exhausted. Very often an apparently exhausted bed may be revived by a good soaking of warm liquid-manure. In which a little salt has been dissolved. On cold nights now, if the temperature falls below 50 degs., fires must be lighted; up to the present very little fire has been required. Bring on fresh batches of *Seakale* and *Rhubarb* roots as required. Chloery will also be required now.

Cold Frames.

Calciclarla-cuttings will be quite safe covered with mats or a little loose litter scattered over the frame. Frames containing bulbs plunged in ashes should be sheltered from severe frost, so also must Auricula and Carnation-frames. Remove all decaying leaves or other matter from Auriculas. In damp frames a few dry, sifted ashes scattered about will be useful. The plants will not require much water now; whatever is done in watering should be done on a mild morning when the lights can be left open for some hours. To winter frost plants in a frame, unless the weather is very severe, it is not so safe to cover them, but the average person fails. Damp is more to be dreaded than frost; it is comparatively easy to keep out frost by increasing the weight of covering, but damp is an insidious thing, and destroys the tissues without any warning.

Window Gardening.

Cleanliness is always important, but more especially so just now. Moss or weeds in pots are evidences of neglect; dust on the foliage tells a similar tale. The more pain one takes with window plants the more they seem to enter into and form a part of our lives, and it is here where the pleasure and interest of plants in rooms and windows come in. Very little water is required now, and none should be given during severe frost.

Outdoor Garden.

Sparrows, where numerous, often do a good deal of mischief, especially to Carnations. Sometimes it is necessary to net the Carnation-beds, or run cotton threads over them, to keep off the sparrows. White Flies, both *Mrs. Stinks* and others, may be pulled to pieces and replanted any time during open weather; but the sooner the work is done now the better. In planting the slips or pieces cover all the old stems, and press the soil firmly around them. Old stools of Carnations may be treated in the same way. The important matter is to make firm and cover all the old stems. A mulch of old leaf-mould, or old *Mindroom*-beds broken up fine, will be a great help; this mulch will be very useful to many things, such as Rose-cuttings that were planted early in autumn, and which are now getting callused, and will soon be forming roots. Cuttings of *Hesperis*, *Deloselinis*, *Flowery Currants*, *Aspidinths*, and most deciduous shrubs will strike now if planted truly in a shaded border. If it is not convenient to plant finally yet, prepare the cuttings and lay them in till they can be planted, the wounds will be healing. This is a slow process, and cannot be hurried. This is the reason why late cuttings often fail, the March winds blow before the cuttings are callused, and the cuttings die. Notice in one of the seed lists that to hand that seeds of the *Potulana* Roses are offered. There is a future before these little Roses, not for exhibition, but for growing in the garden. They are always in blossom, and a best thing enough to cover the ground would be always interesting.

Fruit Garden.

A good deal of pruning still remains to be done, but I see many are making efforts to fetch an arrears. One of the greatest mistakes the pruner can make is to cut away, as I see some are doing, all the young wood. If ground Apples and Pears stamped right back to the old wood annually cannot bear good fruit year after year. They produce blossoms, but the blossoms or young fruit always fall, and I perceive one or two fruits hang on till the end of the season, there is no flavour; one ought to see well as *Tartan*. How can it be otherwise? It is not the wood that is cut away, it is the fruit, the man with the knife or shears? This is no fancy picture; in spite of all that has been written of the folly of over-pruning, it is still done to a very great extent, especially in villa gardens. In dressing Vines and cherries, in which there ought to have been a little mildew present last spring or summer, it would be advisable to burn a little sulphur in the house, if there are no plants in the house. Of course, the fumes of the burning sulphur will kill any green thing, though it will not injure the Vines if the canes are well ripened. If the sulphur cannot be applied by burning, paint the house inside or clean the plant with soap and water, and apply hot lime-water, in which half-a-pound of sulphur has been mixed, to the walls, and then paint the roofs with the following mixture: Sulphur, half-a-pound, one pound each of lime and soot, and sufficient clay to make it stick. Make it into a thin paint with soft soap and water, or Sunlight-soup will do as well.

Vegetable Garden.

No time should be lost now in sowing early Peas and Beans. If the weather and the soil are both suitable, select the warmest site available—the south side of a wall or building is the best place. Where there are borders in front of lean-to forcing-houses, they are excellent positions for bringing on early crops of vegetables, such as Peas, Potatoes, Horn Carrots, Radishes, Cauliflowers, Lettuces, &c., and if there is a garden anywhere without its early border, set about making one without delay. Shelter is a great deal, but it is not everything. There must be depth of soil, and the soil, the whole of its depth, must be rich. Bright sunshine may not be a good thing if the roots are starved, and it should be the cultivator's object to see that the roots have all the food they require. We are well on in the new year, and *Tomatoes* and *Melon* plants will soon be required for the warm-houses, and pits, and frames. *Lockie's Perfection* is one of the best *Tomatoes* to grow for a private garden and also for market. The *Telegraph* is undoubtedly of first-class flavour, and bears freely, but it will not continue to bear so well all through the season as *Lockie's Perfection*. The *Telegraph* will be showing signs of exhaustion before *Lockie's* has half run through its energy. Sow *Tomatoes* for planting in warm-houses, or strike cuttings from plants in bearing, though I am not much in favour of cuttings at this season. There is never too much vigour in a *Tomato*, unless too much manure has been used. Sow a few *Lettuce* seeds under glass. E. HOBDAY.

Work in the Town Garden.

The advent of the New Year has been marked by a change to severer weather, which, if it continues, will put a stop to all outdoor work, and render the most important part of the indoor routine that of keeping up a genial temperature. It is not so much a matter of skill as it is necessary to be able to hit the right man in the matters of heat and moisture. It does not do to allow the thermometer to fall

too low frequently, even though frost be excluded, for town-grown plants do not possess the vitality of those reared in the country; while, on the other hand, any excess of heat excites an undue amount of growth in comparatively hardy subjects, which weakens them considerably. In the town greenhouse—average temperature 45 degs. to 50 degs. will be found most suitable for the majority of greenhouse and bedding plants at this season. As regards watering, the best rule to go by is to keep things comparatively dry in cold weather, and more especially so in a low temperature; but when much fire-heat is used evaporation is almost as active in some houses as if the sun shone, and unless a fair amount of moisture is supplied many plants will soon suffer. It is almost too soon yet to begin propagating where there is Heliotropes, Anemones, and others should be placed in heat to furnish cuttings. Prune them lightly into shape beforehand, and keep them rather dry at the root until fairly started, but syringe them frequently overhead in fine weather. *Tomatoes* that flowered early and have had several weeks' rest in a temperature since may be similarly treated with a view to secure some early cuttings; but any that may have been kept in heat to bloom until Christmas must not be so treated, as they will not strike. The cuttings of *Lobelia* as fast as they can be obtained, for if left too long the plants frequently die away altogether at this season. Even if the stock of old plants is lost it is an easy matter to raise a fresh one from seed, and Sutton's dark-fine *Lobelia* comes as even, true, and good from seed as any named kind. This is a good time, where there is a nice bottom-land bed, to take root cuttings of the graceful and useful *Ornangus*, of which the green-leaved varieties, such as *D. Julia*, *D. australis*, &c., are excellent town plants, and will stand almost as much smoke, dust, and neglect as the notoriously hardy *Aspidistra*. Fern spores sown this month or next usually succeed better than if left till later, and such seeds as those of the *Indian Feather*, *Pteridium*, *Centaurea*, and *Mintulus* ought also to be started in good time. R. C. B.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from January 13th to January 20th.

Made up hot-beds for Potatoes and other things. I generally make these up in blocks, a block being wide enough to carry two lines of frames. Cucumbers, Melons, and propagating may be done in the frames at the back where the bed is highest, and the frames in the front can be used for Potatoes, Carrots, Radishes, Lettuces, &c. This economises the heat, and the beds are more lasting. Finished laying out the seed Potatoes to sprout. A few rows of *Sharp's Victoria*, a white early kidney, have been started on early border in front of a forcing-house. Where some warmth is borrowed from the house the Potatoes will be protected when they come up. I have generally dug early Potatoes from this border before the frame Potatoes are all finished. The autumn-sown Peas have protuberated by the mild weather, and have come up, and at present look strong. Other Peas have been planted for succession, and I have generally sown some best to make sure. Re-potted a number of *Gloxinas*, which are just starting into growth, and placed on a shelf at the back of the house. They always start away well on this shelf, the warmth just sitting them. Put in more *Chrysanthemum* cuttings. The earliest cuttings are now rooted, and are taken out of the propagating frame and placed on a stage in a light position. Very fine enough is used in the *Chrysanthemum*-house to keep out frost, as I want the plants to be sturdily and hardy. Shredded soil among the spring-sown plants in the beds. The frost does not lay hold of the soil surface in the same way it does a hard-baked crust, and has not the same lifting power, consequently, does not do so much harm. I have still plenty of *Vetch's* self-protecting Autumn Broccoli sowed away safe from frost. Filled in beds in the summer-house with warm manure; the plants are ready, and as the soil is warmed through the plants are set out. *Lockie's Perfection* alone will be planted in the house, and *Telegraph* and *Tomatoes* sown last August. Cleared out plants from the conservatory, and filled up with plants from the forcing-house. Many things are coming on now, including a large batch of *Freesia* and other bulbs, *Stauved* and ridged ground for *Melons*, and trenched up a piece of ground for early Potatoes, to be followed by Strawberries. The latter will be planted early in August. Trenched a piece of ground to be laid out as a strawberry, and planted with some nice bedding. Re-laid Box-edging and turned over gravel paths. Cut down and removed several *Sycamore* and other trees which are injuring plants and other better trees growing near, and thus involved a rearrangement of the undergrowth. Instead of planting in mixtures, the *Laurels*, *Yews*, *Boccs*, *Aucubas*, *Berberries*, *Hollies*, &c., will be grouped together. This will, I think, make a desirable change. Potted more *Tuberose*.

Day Lilies in pots.—Where a greenhouse or conservatory has to be kept gay at all seasons as much variety as possible consistent with a good display of bloom is generally the object aimed at, and among plants that give very little trouble and at the same time afford a pleasing variety to the usual occupants of the greenhouse may be named the different forms of *Hemerocallis* or Day Lilies, more especially the clear golden-yellow *H. flava*, which is such a general favourite. Good flowering tufts of this reach a height of about a yard, and though the individual blooms only last a short time, a succession is kept up for a considerable period. The dwarf-growing *H. dumortieri*, whose flowers are of a deep-orange hue, tinged on the exterior with bronze, is also well suited for this treatment, and so is *H. thunbergii*, the blossoms of which are of a light yellow, more than those of *H. flava*.

In cold or northern districts the operations referred to under "Garden Work" may be done in tendency to a fortnight later than the hints indicated, with equally good results.

The stronger-growing kinds, such as *H. fulva* and *H. Kwanso*, with their double-flowered forms, are not so useful for flowering under glass. The variegated-leaved variety, when in good form, is, however, wonderfully pretty, and with a little protection the variegation is very clear and decided. For flowering these Day Lilies under glass very little preparation is necessary, for where there are clumps established in the open ground they may be lifted, potted into suitable sized pots, and placed in a cold frame, all that is needed being to water when necessary. As the roots get active a little liquid-manure will be beneficial.—H.

INDOOR PLANTS.

ZONAL PELARGONIUMS FOR WINTER FLOWERING.

It is very easy to strike cuttings too soon in the case of these "*Ceraniums*" (a name which I must

struck in 2½-inch pots, which are quite large enough, the first shift should be into 3-inch pots, which will give ample room for a good start. As soon as these are filled (not pot-bound) with roots, 4½-inch pots should be the next shift, and thence into 6-inch pots, and the largest into 7-inch pots later on if desirable. In any case, however, the pots should be thoroughly well filled with roots by the end of August, leaving September for the ripening of the wood in an exposed position. By the end of the latter month the plants should be brought under cover into a dry house or pit where ventilation can be given as freely as possible by night as well as day. When there is the slightest suspicion of damping, or the atmosphere appears to be moisture-laden, some warmth should be applied to keep it dry and buoyant. This warmth will also assist in the development of the flower trusses, and is really necessary to obtain the best results. A night temperature at that time of from 45 degs. to

three will be better. This should give from ten to twelve good blooming shoots by the time they are required. In any case, rather than have to pick out the first flower trusses when formed too early, it is much better to stop once more, provided there is time, than thus to waste the energies of the plants to no real purpose. Any assistance in the way of manure should be deferred until the plants are showing for flower. In this there is one essential object to be aimed at which oftentimes is lost sight of by cultivators; it is that of keeping in check a too rank development of leaf growth, which serves no actual good. There is such a host of varieties in cultivation that it is a difficult matter to really select just a few as the very best of each colour. *Niphetos*, the white variety now illustrated, stands out, however, as one of the very best of the pure-whites. The growth is dwarf and compact, the leaves never large under careful treatment, whilst it is a profuse-flowering kind. It is also well suited for bedding out-of-doors in dry positions. *Swanley Single White* is also a good variety of dwarf branching habit. Of the crimson Lord Rosebery and *H. Cannell Junior* are two of the best; *Lord Chesterfield*, a soft magenta, is a grand variety. In the salmon shades, *Mrs. Robert Cannell* and *Lady R. Churchill* can be strongly recommended. As a dark pink *Maud of Wales* should be noted, as should *Mrs. Wildsmith* of the rose-pinks. Of the bluish-coloured kinds, *Lady Brooke* and *Bridesmaid* are two capital kinds. Another good one to complete a dozen is *Marquis of Dufferin*, a crimson-magenta, also a free-flowering variety. *Niphetos* (here figured), belongs to the *Nosegay* section. As its name implies, the flowers are pure-white, never becoming tinted under the strongest sun. It is the freest and most persistent bloomer of the whole family. I have had plants in bloom continuously for two years in 6-inch pots, with an occasional top-dressing of some plant food. G.

White Zonal Pelargonium "*Niphetos*."

confess I still prefer to that given as the heading) in more ways than one. Firstly, when propagated early, the growth is much under less favourable conditions and is no real gain in point of time; secondly, in striking them early there is every possibility (in private establishments at least) of the young plants being crowded together through want of room by reason of the bedding plants taking up so much space. In this way all receive similar treatment, whereas those now under notice should have as favourable a position as can be accorded them, even from the time of striking the cuttings. In striking the cuttings, it is better to insert each singly in a small pot to prevent the earliest growth from becoming drawn, as well as to avoid a check in the first potting off. A frame or pit with a moderate warmth, and not any excess of moisture, will do well for propagating, or they may be struck in houses on shelves where a little shaded. When safely rooted, a lower temperature will be better in every way. Supposing the cuttings have been

50 degs. will give a good return in flowers, allowing, of course, a corresponding rise during the day. "*Ceraniums*," it should be borne in mind, do best in a dry atmosphere. They are also found to do in chalky soils out-of-doors. This should point to the fact that some lime-rubble broken up finely and mixed with the soil is good for them. Failing this useful article, some bone-meal will do almost as well, being easily assimilated by the plants, although it does not keep the soil quite so open. As to soil, nothing can surpass good silicious-loam and the best of leaf-mould, one-fourth of the latter to three-fourths of the former being good proportions. Firm potting is decidedly the best, as it keeps in check any tendency to rank growth, which ought to be avoided. In the early summer, as soon as all danger of frosts is over, the plants should stand out-of-doors in a sunny spot upon a bed of ashes at a fair distance apart, as in the case of forced Strawberries in growth. Two stoppings at least will be useful if the plants have progressed in the best manner,

5250.—**Hydrangeas in pots.**—There will be no difficulty in flowering these by the dates you mention. They are naturally deciduous, so, of course, you lose the leaf, as you describe. Cut them back to the sound eyes near the base. Some will be more prominent than others, and it is these which will carry the finest heads of flower. Feed them well when growth is active, but do not repot, unless in very small sizes now. Plenty of water, light, and an ordinary greenhouse temperature will grow them very well.—P. U.

— These should be pruned rather severely (see reply to 5245). After pruning keep them rather dry at the root for a time, but place them in a genial warmth, and syringe frequently overhead. When well in growth repot them, and push them on with plenty of water and liquid-manure. They require free ventilation and abundance of light.—B. C. R.

5245 and 5250.—**Treatment of Hydrangeas.**—These plants make their growths and the flower-shoots the year previous to flowering; if they are weak no flower-heads will be produced. Although the flower-heads are produced from the growths of the current year, they will not flower if the wood is not vigorous and well ripened. Some persons have an idea that the pruning-knife is essential in the culture of all kinds of plants and trees, taking much pleasure in cutting and slashing. A well-grown *Hydrangea* makes stout, short-jointed young wood, and if it is too crowded cut out the weak growths in summer, but do not use the knife at all in winter.—J. D. E.

— Supposing the plant to be in a pot, and of large or moderate size, all the weak shoots or spray should be cut out altogether, and the strong shoots (of last year) be cut back to within two or three strong eyes of their base. If a very large specimen is wanted do not prune quite so hard, leaving the principal shoots about a third of their present length. Plants in the open ground may be treated somewhat in the same way, but as a rule they do not require nearly so much pruning as pot plants.—B. C. R.

— Your plant will need no more cutting than the frost will effect. Simply trim back to the sound wood in March. We should not get the grand specimens found in the southern counties if they were cut down to the ground annually.—P. U.

— *Hydrangeas* form flower-buds on the ends of the shoots, and if the plants are cut down there will be no flower. Plants of trailing, upright habit may be pruned, but not others.—E. H.

CLEMATISES IN POTS.

We do not often see these grown in pots now. Why, I cannot say. I remember some grand collections at the Royal Botanic Society's exhibitions, held some years back in Regent's-park, but for the last six or seven years an occasional well-grown plant is all I have seen in private collections. It is difficult to account for this when we bear in mind how easily the Clematis is grown, and how certain a bloomer it is. If the individual flowers do not last long in the open air, and show signs of being weather-beaten when wind and rain prevail, we can remedy this by growing them under glass. The double varieties will keep fresh for weeks, and are very useful as cut flowers during early spring. Some of the varieties found among the Patens and Lanuginosa classes are grand in size, form, and colour, while more than one of them are exquisitely scented. I think we may safely say that few plants will give more show for the same amount of trouble; nor can the amateur with an unheated or barely frost-proof house find a genus more suitable for spring and summer blooming. I am dealing with plants in pots only, so their grand qualities as climbers, both inside and out, must be left for a future note. One most

IMPORTANT ITEM when cultivating the Clematis is knowing to which class or section a variety belongs. Until we understand the characteristics of each section, we shall not be certain of success; therefore, we will look into this point at once. Clematises are divided into several classes, but the four most suited for pots are the Patens (see cut), Jackmani, Florida, and Lanuginosa groups, and I propose giving a note upon each. The Patens and Florida groups flower upon the matured wood of the previous season, and this must be borne in mind when pruning. Both of them produce huge growths from the base after having flowered. In order to increase the strength of these shoots it is well to cut away the two-year-old wood as soon as the blooms have been secured. It is a good plan to train the two or three long growths up the roof of the house. I tie them to a piece of string stretching from the pots to a parlin running through my house. There would be a considerable amount of attention needed to train the growths over a wire globe or trellis work as they grew, and I find the above plan much easier, besides affording more light to mature the wood. At any convenient time during the winter the plants are repotted and the wood trained around globes or not as desired, this being cut away after it has bloomed, and more young growths trained up the strings as before. If the room should be needed for other purposes, the Clematises may be stood out-of-doors after the middle of June, where they will finish their growth equally well. Do not stand them against a hedge and allow the growth to rambles among it, or you will probably have much difficulty in clearing the wood later on without injury.

A FEW GRAND VARIETIES among the Patens class are Albert Victor (deep-lavender), The Queen (delicate-lavender), Miss Bateman (white, with deep-rose centre), Fair Rosamund (bluish-white), and Lord Londesborough (a deep-mauve). These are all single and very large blooms. On the other hand, we find all doubles in the Florida class, and although we have Beauty of Worcester, from the Lanuginosa section, producing both double and single blossoms of a bluish-violet shade, the best double are Belle of Woking (silvery-gray), Conatess of Laverack (silken), and Duchess of Edinburgh (pure-white). The last named is particularly sweet-scented and pure. In the Jackmani section we have a group which flower from the wood made early in the spring. The growths are long, like the Patens and Florida sections, but are produced earlier, and when their length is attained they commence blooming from the point backwards, giving flowers from almost every joint. When this growth has become it is of no further use, and may be cut down. In the meantime the plants may stand in any odd corner until their next lot of growth commences from the base, when they should be grown on as before. An enormous lot of bloom is produced by this class, and an 8-inch pot will carry enough wood to completely clothe a globe 3 feet or 4 feet in diameter. Jackmani superba (dark-purple), Jackmani alba (white), Jackmani "Smith's Snow White" is a grand addition sent by Messrs. R. S. & Co.

and Co., Worcester; Alexandra (pale-reddish violet), Gipsy Queen (velvety-purple), and Star of India (deep-reddish-pink) are only a few of the gems in this section. Treat this class as herbaceous perennial climbers.

THE LANUGINOSA SECTION make growth not quite so strong as the Patens and Florida varieties, but instead of flowering like them they bloom in succession upon short laterals from the long growths. We see that the Patens and Florida classes bloom on the wood made the previous season, after which it is useless. The

Flowering spray of Clematis patens.

wood of the Jackmani class carries a crop of bloom the same year, and may thus be cut down; but that of the Lanuginosa merely needs a few of the weakest growths to be cut away each spring, the stronger growths being left permanent. Otto Probel is a sweet-scented white of immense size; Henryl is also large, perhaps the largest blossom in the whole genus. Alba magna (pure white), the Gem (deep-lavender), Blue Gem (a sweet curulean blue), and Beauty of Surrey (soft greyish-blue) are but a few of the numerous grand varieties to be found in this section. Grand new Clematises are being introduced yearly, and it is quite impossible to name more than a few in each of the above sections. I hope these few notes will have shown the immense importance of correct pruning when cultivating the Clematis, so I will close with a general hint or two on the whole genus. If small plants are purchased from the trade growers they may be shifted into 6-inch pots at once, using good dressings and a rich, loamy compost, having a fair sprinkling of 3-inch bones and soot. Clematises are very voracious feeders, and will benefit from liquid-manures when growing. They also like plenty of moisture from the time new growth commences until their wood is matured. The pots soon become crammed with roots, and unless a heavy mulching can be applied it is a good plan to repot them each other year. When this is being done pick out as much of the soil from the mat of roots as possible; nor need we hesitate to cut a good deal of their roots away where matted so extra thickly, as we often find them. The temperature of a cool greenhouse will suit them admirably, but they are also at home in almost a stove-heat. Few insects attack them, the chief pest being aphids, and these only when surrounding subjects are also troubled with them.

I. U.

5246. — **Veronicas in pots.** — These plants, when grown in pots, do not require more than a cool greenhouse temperature. In fact, some of them are hardy enough to stand through the winter in the open air in England. Their culture is very easy, as they are free-growing plants, making masses of fibrous roots when growing, and they must be shifted from one

flower-pot into another before they become what gardeners term pot-bound—that is, the roots matted round the inner surface of the flower-pot. The best soil for them is a compost of two parts good fibrous yellow loam to one of peat; a little decayed manure and sand should be added; not much, as the plants are likely to grow too rampant. Leaf-mould may also be used in the place of peat, if the latter cannot be obtained, as the Veronicas are not over particular as regards the compost used to grow them in.—J. D. E.

— These do not require more than a greenhouse temperature, and are excellent plants for the amateur to grow, as they are not difficult to cultivate, whilst they bloom freely through the autumn and early winter months. It is a pity that more interest is not taken in this class, as there is no lack of variety, many with flowers of beautiful colour. One of the best is V. Andersoni, which has dark-green leaves and blue and white flowers in dense spikes, whilst the variegated form is quite a foliage plant, the leaves green, variegated with creamy-white, a very distinct and handsome variety. Blue Gem is dwarf, free, and the flowers bright-blue. Celestial (sky-blue), Impératrice (rich-blue), Marie Antoinette (pink), Evoline (rose-lilac, the habit of the plant in every way good), Diamant (deep-red), and Reine des Blanches (pure-white). In the more southerly districts of England, in Devonshire and sheltered parts along the Cornish coast, the plants are quite hardy, but otherwise must have the protection of a greenhouse. The best results are got from plants planted out during the summer months, and lifted when frost approaches and transferred to pots, keeping up a gay display in the greenhouse until Chrysanthemums are in full bloom. Suppose one is going to commence with cuttings, get these from half-ripened wood in the late spring or earlier. They will strike readily with a little artificial heat, and flower moderately well the first year, but really well the second season. If you have no opportunity of planting them out during the summer, they must, of course, be kept in the 5-inch or 6-inch pots in which they were placed at the final shift, but very careful attention will be necessary to keep the soil moist. If possible, plant them out in early June, loosen the soil a little round the ball, and plant out in rich, light soil, the best way of promoting a vigorous growth, and plenty of fibrous roots. One or two stoppings of the chief shoots may be given, but not after the first few days in July. At the latter end of August or early September, take up the plants and put them into as small pots as possible without unduly cramping in the roots. Six-inch, or even 5-inch, will, as a rule, be sufficient size for amateurs with small greenhouses.—C. T.

— These pretty plants (the shrubby varieties) are of the easiest possible culture, and succeed admirably with a minimum of heat, or even in a cold house, in either country or town gardens. Cuttings of the half-ripened shoots will strike readily in sandy soil in a very gentle warmth, or even under a close cloth frame or haultlight, at any time during the summer, or when a little harrier they may be inserted in the autumn, and will mostly form roots if only frost is kept away. The following spring they should be potted singly into 3-inch sizes, using good fibrous or sandy loam, with half the quantity of leaf-mould or peat; grow them on for a time under glass, but with plenty of air, pinch out the points once, shift into 5-inch pots when broken into growth again, stand them out of doors in August, and they will bloom beautifully in September, October, or later. I have some beautifully in bloom now (January 2) in a house from which frost is only just excluded. They thrive best with firm potting and free drainage, watering abundantly in hot weather, and not allowing them to become very dry even in the winter, as they are of an evergreen nature, and nearly always in either growth or bloom, more or less. Old plants should be moderately pruned in the spring, and repotted when they break into growth again.—B. C. R.

— These are easily propagated from cuttings, and grown into flowering plants in 5-inch pots in one season, if the cuttings are taken early in spring. The New Zealand Veronicas are fairly hardy in sheltered places, and the other species, of which Andersoni may be taken as the type, may be grown in a cool greenhouse.

In a mild season they will live through the winter outside. The same soil and treatment that will grow a "Geranium" or Fuchsia will grow the greenhouse Veronicas. Old plants may be cut back in spring and repotted when the buds break. These will make large bushes and flower to the end of summer and autumn, whilst the cuttings root in spring will flower in smaller pots.—F. H.

—A cool greenhouse temperature is very suitable for them, as they are not quite hardy, unless in a very warm and sheltered locality. Veronica Traversi is about the hardiest. A rich, loamy, compost will do them well. Keep them frequently syringed while not in bloom, and avoid too much heat with close atmospheres. Treat like other half-hardy shrubs.—F. H.

5278.—**Solanum Capsicastrum.**—The shrubs must be well thinned out, for if much crowded they will be too weak to fruit freely. Stop the growth in May to make them bushy, and in June either plant them out again or shift them into 6-inch or 7-inch pots, and when a little established stand them on ashes in the open air. They make the best plants in this way, as the lifting checks them sadly. Give them plenty of water and liquid-manure in hot weather, and in September prick out the point of each strong shoot. Seedling plants never berry to any extent until the second or third year.—B. C. R.

5214.—**Carnation Souvenir de la Malmaison.**—The delicate petals of this beautiful flower are easily scalded by the sun when under glass, especially so when the flowers are rendered soft by the use of strong manures. Water will also cause this if allowed to get on the petals from drip or from springing.—F. B., *Witchester*.

MIGNONETTE IN POTS.

MIGNONETTE for early spring flowering may now soon be sown. Where only a limited quantity is required, a shelf close to the glass in a house where just sufficient heat is given to keep out frost will be the best position, or a mild hot-bed in a pit will bring the seed up quickly. In the neighbourhood of London or any place where fogs prevail, it requires some care to keep the early sown Mignonette from getting spindly and weak, and it is liable to dump off while in the seed-leaf. During bright weather a little warmth with plenty of air will be beneficial, but in dull, foggy weather it should be kept as cool as possible. Although the early-sown Mignonette requires a little extra care, it will well repay the trouble, for it will come into flower at a time when it is most appreciated, and last better than that which comes into bloom after the weather is warmer. Any plants that get too thin or straggling for flowering in pots will be useful for planting out. In growing Mignonette in pots it is essential that the pots should be filled firmly with a good, loamy compost, with which may be mixed a good proportion of well-rotted manure.

Soot should be mixed with the manure before adding it to the other compost; this will kill any worms or other insects. Old lime rubbish is also a valuable addition, especially for the early sowings, as it helps to keep the soil sweet. The seed should be sown fairly thick, and as soon as the plants are large enough they may be thinned out, but not too much at first. From six to nine plants in a 5-inch pot will be sufficient after the final thinning. Plenty of light and air is essential, but cold east winds are very damaging, and it will be better not to give air than to expose the plants to a direct east wind. As soon as the plants are large enough to require it they should have water round, and when they are an inch or from that to 2 inches high liquid-manure may be used, commencing with it well diluted and gradually increasing the strength. Great care should be taken that it is used in a clear state. I find a great difficulty in making young men understand that all liquid-manures should be allowed to settle down and never be used except in a clear state. Thick, muddy manure not only stains the foliage, but it forms a coating over the surface of the soil and effectually prevents capriciation and absorption. There are some

VERY DISTINCT VARIETIES OF MIGNONETTE, but names are rather misleading. The varieties may be divided into three distinct forms—viz., red, white, and yellow. In the red varieties the colour is given by the numerous anthers, the petals being of a greenish-white and inconspicuous; in the yellow the anthers are yellow,

and in the white varieties the petals are much enlarged, and the anthers are very small and sometimes entirely absent. Parson's White was the first distinct white variety, and although there are now many different names, I have not met with anything better than the original. The best and most distinct red variety is Vilmorin's grandiflora. I do not know the history of the yellow variety, Golden Queen. All the above may be obtained under various pet names. I may mention Macliet as another distinct form; this has very thick spikes of bloom of a greenish-white. This and Vilmorin's are the most popular for market work. While speaking of varieties I may allude to the curious double variety shown by Messrs. Bolehin and Sons a few years ago. In this variety the seed-vessels were superseded by lateral spikes of bloom, the lower ones running out to some length, the original petals much enlarged and white. A most interesting variety, but it can only be propagated from cuttings. H.

ORCHIDS.

CATLEYA AMETHYSTOGLOSSA.

The first plant which I ever saw of this was in the garden of H. P. Reichmheim, in the Tein garden outside Berlin. This was thirty years ago, and I afterwards saw it as a unique specimen in England in Mr. Warner's collection. Soon after this the Messrs. Low and Co., of Clapton, received a fine lot of it; but not many, I think, equalled Mr. Warner's plant. The Messrs. Low have every now and then large consignments of this Orchid, which keep it well before the public, for the beauty of its flowers commands it to everyone, and it appears to exist in very great quantities in its native place, so much so that I do not think this a variety of *C. guttata*, as some authors call it var. *Prunzi*. I rather here adopt the name given it, I believe, by Linden. The plant certainly has some resemblance to *C. guttata*, yet I think it is quite distinct. It has somewhat slender, erect, stem-

Cattleya Amethystoglossa.

like pseudo-bulbs, which usually attain a length of 2½ feet, and I have seen the bulbs reach 3 feet and more. These bear upon the points a pair of large leathery leaves, and from between these the scape appears, bearing many flowers, which vary much in size and colour in different plants. This might be expected from a plant that seeds freely and evidently grows in a spot well suited to the development of the young seedlings. The flowers each measure 5 inches or more across, the sepals and petals being nearly equal, thick and waxy in texture, creamy white, suffused with a tinge of rose and spotted, more especially near the margins, with

numerous spots (not blotches) of rich rosy-purple.

THE SIDE LOBES of the lip are erect, in colour about the same as the ground of the sepals and petals, the tips reflexed and of a rich amethyst-purple. The middle lobe is of a rich and bright amethyst-purple. The flowers last in full beauty for a month, and they do not injure the plant if allowed to remain on for that period. I like to allow the plants to remain in the house in which the flowers open far better than to remove them to another, which is sure to be moister or drier, and to have some variation in temperature, either of which affects the duration of the flowers to a surprising extent. Its usual time of flowering is the spring months, but I have seen its flowers at all seasons. Last season I noted a very distinct and handsome variety flowering with Mr. Sander, of St. Albans, and this was not a recently imported plant either. It would be a desirable acquisition if we could ensure its flowering regularly at this dull time of the season. To grow this plant so that it will continue to make bulbs strong enough to bloom annually has somewhat puzzled the majority of growers. I usually find that it becomes smaller after about two or three seasons, and I am of opinion that it does not like such cool treatment as most of the Cattleyas are subjected to. I think the best place to winter this is with plants of *Laelia clegans* in a house that does not at any time fall below 60 degs. If at any time the plant appears to be inclined to move too soon, it should be set where more air can play upon it, and it should be kept a little drier; but I am totally opposed to the roasting system which used to be applied to this family. G.

A good amateur's Orchid.—A really good Orchid for an amateur to grow in his collection is *Odontoglossum Rossi majus*, which will succeed well in either a pot or a basket. It is easily grown in the cool-house, and the flowers last in beauty for many weeks during the winter. They vary considerably in colour, but the variety *majus* is as good as any, the flowers borne in pairs, with white petals and sepals spotted with purplish-brown, whilst the lip is large and white, the crest yellow. It is an excellent Orchid for cutting, one of these richly-marked blooms making a good flower for the coat. In the smallest collection this should be grown for its beauty and easy culture.—C. T.

GARDEN REFUSE.

THE above term includes all that is supposed to be of little value in the garden, but which often gives the grower of choice vegetables and fruit just the materials required to mix with unsuitable soils. At no season of the year than now is there a better opportunity to secure these aids to enrich the soil, at the same time doing a vast amount of good by the removal of useless, often unsightly material. One of the best manures we have is wood-ashes, which most plants in a vigorous state like. At this period the quarters occupied by last year's crops will require to be got in readiness for the next season's crop, and in gardens of any age with plentiful supplies of manure failures often occur by clubbing, wireworm, and other insect pests. There is no better remedy than stepping the supply of animal manure and treating the soil to liberal dressings of wood-ashes, lime, or burnt garden refuse. In case any doubt exists as to the richness of the soil, wood-ashes may be used, adding a liberal quantity of guano, or the latter may with advantage be applied as a top-dressing. There is always from this date till late in the spring a wealth of material that may be converted into charred refuse, as all prunings, useless growth, stalks of Cabbages, Cauliflowers, or any of the Brassica tribe may be utilised for this purpose, and if a large quantity cannot be secured, certain quarters may be attended to, doing the worst each season. It is surprising what a mass of suitable material can be secured when means are taken to collect and prepare for this purpose. There is no better fertiliser than charred refuse for soils badly infested with wireworm, adding a small quantity of gas-lime. For Asparagus-beds in heavy clay soil the garden refuse, after having been placed in heaps with a liberal quantity of quicklime and turned occasionally, is of great

value. Leaves, which are often very plentiful, may always be turned to valuable account. They decay rapidly if placed in sunken pits or covered with soil and saturated with liquid-manure. Mortar rubble from buildings should always be utilised for fruit-trees, and if not required at the time should be stored for use when required. If there is any surplus matter that is not sufficiently decayed, allow it to get all the moisture possible, giving liquid-manure or drainings from manure heaps. This will soon be in condition, and may be used to advantage for such crops as Beet, Carrots, Parsnips, &c., later in the season. G.

OUTDOOR PLANTS.

TALL-GROWING WINDFLOWERS.

AMONGST the hundreds of hardy flowers grown in gardens, few genera are more popular than the Windflowers. They are pretty evenly distributed in temperate regions all over the world, and from the tiny vernal Windflower (*A. vernalis*) of our high Alps to the gigantic *A. Fannini*, recently introduced from Natal, where it blossoms from September to December, we have almost every gradation in height, habit, size, and colour of flowers. From the dazzling *A. fulgens*, through the magnificent and varied shades in *A. coronaria*, to the insignificant *A. pennsylvanica*, we have yellow, purple, blue, &c., all of them with a distinguishing character. The new *A. Fannini* has large, white, fragrant flowers, 3 inches in diameter, its leaves, when full size, measuring from 1 foot to 2 feet in diameter. It is said to have stood our winter in the open air, but we are not aware of its having flowered outside yet. It is, however, likely to prove a useful flowering plant in the cool conservatory, where it should be planted out in a light place and plenty of room allowed for development. Windflowers, as a rule, prefer deep, rich soil, light and gritty for the running kinds, and rather on the moist side for those from the high alpine pastures. If arohalde, they should never be disturbed. The majority of them are readily propagated by root division and by seeds, which they ripen freely in most seasons. These should be sown as soon as gathered, when they will quickly germinate, and a season thereby be saved. The following notes refer only to the tall-growing species known to us in cultivation:—

ALPINE WINDFLOWER (*A. alpina*), although one of the very commonest species in alpine districts, being found on almost every mountain in Southern Europe, is by no means so plentiful in gardens as one would suppose. This may in a measure be accounted for by its slow growth, its dislike to being disturbed, and the probability of its being what we call a short-lived plant. It is a variable species, and has a large and complicated synonymy, so many botanists having named the merest varieties and classes them as species. The most distinct variety known to us is one called sulphurea, *A. alpina* var. *apifolia* of the botanists. The flowers in this plant are pale-lemna or sulphur. It makes a charming border plant, beautiful in flower and also in seed, the bunches of long feathery tails being very effective in autumn. The type grows from 1 foot to 2 feet in height, forming long strong roots, which require a deep soil well drained, and with a quantity of old mortar mixed with it. The flowers are white, pale-purple outside, distinct, and showy. The leaves of both are deeply cut, fern-like, and effective when grouped. It flowers in April and May.

THE JAPAN WINDFLOWER (*A. japonica*) is decidedly the finest of the tall-growing Anemones yet introduced, and one of our best autumn-flowering hardy plants. It is a native of damp woods on a mountain called Kifune, in the neighbourhood of Miako, Japan, and was first introduced into England by Fortune. It has lately been found in Burmah, however, and may have a still wider distribution than we are

posed. If disturbed, the Japan Windflower takes a long time to become established again, but even more years being required to overcome interference unless very carefully handled. My plan, which I think a good one, is to establish offsets in shallow boxes, and plant out the whole without breaking the soil. The white variety *alba* or *Honorino Jobert* is particularly handsome and easily managed; the great secret seems to be to prepare at first a good deep bed of rich heavy soil and to leave the plants alone. *A. j.* var. *hybrida* or *elegans* is said to be a cross between *A. japonica* and *A. vitifolia*, a nearly allied Himalayan species. We have no means of either disputing or verifying this statement, but from our knowledge of *A. vitifolia* we would doubt very much its being one of the parents; the probabilities are, as in the case of *Honorino Jobert*, that it is a break, or sport, or else a seedling. When fully established, and showing signs of degeneration, supply the needful in the shape of a heavy top-dressing, and this left on the ground all through the summer will be found beneficial.

A. narcissiflora, of which the illustration represents the flowering stem, is a charming hardy species distributed in the Alps of Central and South Europe, Western Asia, Siberia, North-west America, and also in the Himalayas. It is by no means a common plant in gardens, although a very useful and showy species. It is one of the freest flowering in the group, each stem carrying (see cut) a large head of fine delicate white flowers in a setting of bright green leaves, and making in itself quite a charming bouquet. It does well in the ordinary border, requiring a sunny spot and rich light soil. It makes a fine display in early summer when doing well. It is said to be allied to *A. polyanthes* by intermediate forms, none of which are known to us in cultivation at present. *A. narcissiflora* rarely exceeds a foot in height; the leaves are palmately five-parted, and the divisions deeply cut into narrow linear lobes. It deserves a place in choice collections.

A. polyanthes. This is one of the most

Anemone narcissiflora.

charming and, so far as my knowledge of Himalayan Windflowers goes, one of the worthiest of a place in the flower border or rockery. It is found at an elevation of 10,000 feet to 12,000 feet above sea level, and is quite hardy enough to withstand all the vicissitudes of our severest winters. It is not at all particular as to soil or situation, and flowers with a profusion only surpassed by the Japanese species. It usually blooms in June and July, coming in between the earlier and later forms, continuing in flower until succeeded by *A. vitifolia*. In partially-shaded positions it grows

higher than in the open, varying from 1½ feet to 3 feet, and bearing an abundance of flowers quite equal to any of the other species. It has been confounded with *A. obtusiloba*, a species with golden-yellow flowers, not, so far as I know, in cultivation at present. In *A. polyanthes* the stems and leaves are densely silky, the latter five to seven-lobed, about 4 inches in diameter, and having long petioles. The flowers are about 2 inches across, many in an umbel, white or tinged purplish on outside, and very showy. It is increased either by seeds or division. The seeds sown when gathered give no trouble.

A. RIFULARIS.—This is a well-known garden plant, and a good second to polyanthes and others of the tall-growing section of Windflowers. It is perhaps one of the easiest to manage, making an excellent border plant, and not being at all particular as to situation. The roots do not run so much as in some of the other species, and it is, therefore, not so troublesome to keep in its place. The rootstalk is stout, the lower leaves three times divided, the segments lobed and evenly serrated. It generally grows from 2 feet to 3 feet in height, bearing flattened heads of many flowers, star-shaped, 1 inch to 2 inches in diameter, white, and often purplish-tinted outside. It flowers in summer, and is perhaps the commonest Windflower of the temperate Himalayas. Increased by seeds and division.

THE SNOWDROP WINDFLOWER (*A. sylvestris*) is not, strictly speaking, a tall-growing species, and should hardly be included here were it not for its charming free-flowering habit, its woolly seed heads in early autumn, and its adaptability to the wild or natural portions of the garden. It should be naturalised in quantities, both in our woods and shrubberies, where, if the ground is free from strong weeds, it will soon establish itself and form large groups, under which condition it is always seen to best advantage. It flowers in May and June, the blooms being followed by the woolly seed-heads, which hang loosely together for a long time. The flowers are large, white, and in the bud state drooping and somewhat resembling Snowdrops, hence the common name. It is easily propagated by offsets, which may be planted as desired when taken off. It is a native of Central Europe and Siberia, and should be in every collection.

A. VIRGINIANA.—An American species of no mean beauty, but unruly in habit, and only fitted for the shrubby border or the woodland, where it can run at will and take care of itself. The flowers, which are pure white, are produced all through the summer. Its nearest ally, *A. pennsylvanica*, is a weed that never ought to find a place in the garden. Also a native of North America.

A. VITIFOLIA.—A rare and beautiful species from Nepal, where it is said to be one of the commonest of native flowers. It is one of the reputed parents of *A. japonica* var. *hybrida*, and although much resembling *A. japonica*, it is readily recognised from that species, and flowers much earlier. It thrives best in a somewhat shady spot, or where the soil is stiff and rich it will do well in the open. It gets damaged in severe winters and should be protected when the weather is at all severe. It grows from 1 foot to 3 feet in height; the lower leaves are from 5 inches to 8 inches in diameter and deeply five-lobed. They are smooth above, but densely covered with a thick tomentum beneath. The flowers are borne in decomposed flattened panicles, pure white, and about 2 inches in diameter. It may be increased by division or seeds. D.

Campanula persicifolia alba.—This useful, well-known herbaceous plant was well to the front last season in spite of the drought. It is one of those plants which grow so easily that it is often neglected for that very reason. It is a plant which amply repays liberal treatment, and should be taken up and replanted every two or three years, and should get a good dressing of manure every spring.—F. H. Wilschetter.

555.—**Auriculas in a garden**.—These flowers are like everything else, they cannot be expected to do well if they are neglected. It is the nature of the plant to lose many leaves in the course of the season, and as it grows and the leaves fall off, the plants stand well out of the ground with naked stems. This, of course, would not happen if they had been replanted annually, as they ought to have been; or, if they were not replanted, fresh soil ought

to have been put amongst the stems. The leaves being amongst them would have been a sort of natural protection, and if the tops were clear of the leaves it would have been better to let them remain. The best thing to do now will be to surface-dress them with rich soil, and put on sufficient to cover the naked stems.—J. D. E.

— All that can be done at present is to heap some fine sandy soil or coal-ashes round the bare stems of the plants, as this is a vulnerable part, and the probable reason of so many dying off. In the spring you will be able to see which are worth keeping and which not, and the best should be divided and replanted as soon as the flowers are over, planting them deeper, and putting my small or unrooted offsets into sunny soil in a cold frame or under a handlight to gain strength.—B. C. R.

— Give them a top-dressing of leaf-mould, loam, and sand. It will shelter and protect the stems, and they will soon form roots in it, and in spring they may be divided and replanted.—E. H.

5231.—**Anemone-roots and worms.**—The worms are probably the Snake Millipede. The best remedy I can find, when it is not possible to remove the plants attacked, is to attract the worms into some other soil, such as decaying Apples, pieces of Potatoes, &c., buried in the soil and left a few days, when they will be found swarming with them; they are then collected and destroyed.—F. H., Winchester.

5247.—**Rock plants.**—Many plants are suitable for the purpose, but you must remember good treatment is necessary. If the rockery is well constructed, plenty of rich, fibry soil and comparatively few stones, and the position is not, as too often the case, near to trees, or even under the shadow of them, the following plants would succeed: *Acaem microphylla* (which is quite dwarf, has crimson spikes that give colour to the plant, the flowers being inconspicuous), the golden-flowered *Alyssum saxatile*, *Audra suce lanuginosa* (in warm, light soil), Alpine Anemones, the beautiful *Vinaria vulgaris peloria* (a really showy and interesting flower, pale yellow, orange at the apex), *Arabis albidia* (which is, however, a little too rampant, but will do for the rougher parts), *Arenaria balearica* (a creeping herb, which coats the facings of the stones with greenery, spangled with white flowers in summer), Thrift, Dwarf Bellflowers (such as the deep blue-purple *Campanula patula*, the White *C. pumila*, *C. muralis*, and others), *Cyclanema* (for blooming in winter, *C. ibericum* and varieties), Alpine Pinks, *Dryas octopetala*, Hardy Heaths for the rougher parts, *Gentianella* and *Gentiana acaulis* (the flowers in both cases of deepest blue colour), *Gypsophila paniculata* (a spreading plant with a wreath of small flowers, very charming for cutting), Christmas Rose, *Iberis* (*I. gibraltarica*, *I. scaberfolens*, and others), Dwarf Irids and the beautiful bulbous kinds (as *I. reticulata*, which has deep-purple sweetly-scented flowers), *Edelweiss*, *Lithospermum prostratum* (deep-blue flowers in early summer), Golden-leaved Creeping Jenny, Golden Drop, *Onosma taurica*, Dwarf Phloxes, Alpine Primulas, Mossy Saxifrage (as *S. hypnoides*), Scillas of kinds, Sedums, Thymes, *Trillium grandiflorum* in a shady and moist corner, and various dwarf bulbs. With these plants, or any of them, you may get a very interesting rockery.—C. T.

— *Acantholimon glumacem*, *Ajuga reptans atro-purpurea*, *Alyssum alpestre*, *A. montana*, *A. saxatile compactum*, *Antennaria tomentosa*, *Arabis albidia*, *A. a. variegata*, *Arenaria balearica*, *Ambrosia deltoidea grandiflora*, *A. Hendersoni*, *Campanula carpatia* (blue and white), *C. gorgonica*, *C. isophylla alba*, *C. pumila*, *Daphne Cneorum*, *Dianthus alpinus*, *D. deltoidea*, *Gentiana acaulis*, *Hutchinsia alpina*, *Lithospermum prostratum*, *Linaria pallida*, *Linum flavum*, *Lysimachia Nummularia aurea*, *Omphalodes verna*, alpine Phloxes in variety, including *P. procumbens*, *setacea*, *atro-purpurea*, *Bride grandiflora*, &c., *Silene acaulis*, *S. grandiflora*, *Saxifragas* in variety, including *S. Bursseriana*, *longifolia*, *ruscularis*, *nullosa*, (London Iride), *hypnoides*, *Wallacii*, *oppositifolia*. Then the Sedums and *Sempervivum*, or Houseleeks, are all suitable, and will give but little trouble to establish. *Veronica prestrata*, *V. repens*.—E. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the best manner and will appear in the next issue of GARDENING ILLUSTRATED.

CHRISTMAS ROSE (HELLEBORUS).

THE White Christmas Rose is one of our most valuable hardy perennials, flowering, as it does, in the open air in the dead of winter, when little else is in bloom, coming in particularly useful for Christmas, when flowers are wanted in plenty, but are somewhat scarce. But, as a matter of fact, the season of the Christmas Rose extends from October into April. It commences with the white-flowered kinds, of which *H. niger* is typical and best known, and it closes with the red-flowered sorts, the finest of which is *H. colchicus*. These last are often called

stagmat-kind, and partial shade is an advantage, such as would be afforded by a wall or a shrubbery. Only in this last case on no account should the roots of the shrubs be allowed to run through the soil and exhaust it, or the plants will certainly fail. It is much better in the case of these Hellebores to devote a small bed or border to them exclusively, as then their little cultural requirements can be the better attended to. Planted in a soil and situation such as advised above, they ought to thrive, and nothing more remains but to advise the placing of a thin mulch of Moss, or some clean material, among them as the flowering season commences, as

Fine Christmas Rose (*Helleborus Commertzenrath* Benary). (See page 644.)

Lenten Roses—but more of them later on. We will take them in the order that they come, and glancing at the white-flowered sorts, detail their merits, many uses, and most successful.

METHOD OF CULTIVATION AND INCREASE. *H. niger* is easily known by its thick glossy leaves and white flowers. No plant better deserves, or better repays, good cultivation, but some are not successful with it. Plants of this kind are imported by tens of thousands, and are offered at a most alluring rate to induce amateurs to buy them. My advice is, do not buy. These plants are collected from their mountain homes; they are ruthlessly torn up without regard to the roots, the leaves are cut off, they are packed closely in boxes, and forwarded by the collectors to agents, who distribute them. They have a long overland journey, and often get heated on the way, and yet another long journey by land and water before they reach England. They are described as being full of flower-buds, and so they are, but few flowers may be induced to open. The plants may be planted, and the majority of them will die. I once planted 1,000, and did not save 100 of them. It is better and infinitely more satisfactory to obtain from some good English nurseryman healthy, home-grown plants, and these, if planted with care, are sure to succeed, and give good flowers in abundance the same season. Christmas Roses will thrive in any

this will gently ail to keep the blooms clean, by preventing the rain from splashing the soil upon them. These Christmas Roses may be left for years undisturbed, and will then grow into great tufts, but the time will come when they need

DIVIDING. whilst some may wish to perform this operation in order to increase their stock, or it may be necessary to transplant some of the plants to fresh sites and gardens. Transplanting large specimens is almost sure to end in failure and, perhaps, entire loss of the whole stock. When big plants are lifted they should be most carefully divided into small pieces, each one with a few roots attached, and these, if planted firmly in good light soil, soon put forth fresh roots and grow away all right. This should be done in spring or summer, as that is the plants' growing season, and the divided pieces take more readily. If done in autumn and winter the lowering is interfered with, if not quite destroyed, and the divided pieces may perish before they commence to grow. Of course, it is important if dry weather follows upon division that the plants be occasionally watered; but if the site is a shaded one the need of this will not be frequent. All the above applies to Christmas Roses in the open ground, and from this system of culture good and pure flowers may be had in the greatest profusion; but these lovely Christmas Roses are beautiful in pots or tubs, for which purpose they may be taken up, grown, and brought on into bloom under glass. After the Chrysanthemums are over the house might be gay with Christmas Roses, and there the flower would be absolutely pure and

ORDINARY GARDEN SOIL, but do better in a prepared site which has some good fibry loam and well-rotted manure dug into it, whilst the fibrous peat will not come amiss. They love a fair amount of moisture, but do not

unsoiled. Of course, they cannot be annually lifted and replanted, as this would soon spoil them; but the Christmas Rose is so well adapted for

POT OR TUB CULTURE that this method of growing it might be extended. Strong plants may be potted, or several placed in a tub. They may stand outside in a partially shaded spot all through the summer—in fact, for the greater part of the year—only being brought in under glass as they come into flower. If they are treated generously and well looked after they will flower equally as well and freely as the plants in the open ground, and the plants being under glass, flowers can be cut at any time. The beauty of fine specimens in pots or tubs must be seen before it can be fully appreciated, for certainly no other hardy plant better repays good culture in this way. *Helleborus niger* itself is extremely variable. There are some inferior forms of it, and others remarkably fine. *H. utrifolius* is a magnificent kind, larger in all its parts than *H. niger*, its leaf-stalks being 1 foot or more in length, and the blossoms borne on similar long stalks are sometimes as much as 5 inches across. It is probably the finest Christmas Rose in existence, and, moreover, commences to bloom as early as October. Other fine forms of *H. niger* are known respectively as the Riverston and the St. Bridget varieties, both of which bloom at the same time as the common form. *H. olympicus* is a slender-growing, white-flowered species, flowering from January to March. The flowers vary in colour from pure white to a greenish-white hue.

RED-FLOWERED KINDS are interesting and pretty, though not so valuable as the white ones. The best is certainly *H. colchicus*. It is very vigorous, the plant making a mass of rich dark-green leaves, 1½ feet to 2 feet in height. The flowers are of a dark purplish colour, borne on long stems above the foliage, and appearing from January almost into April. Several very fine hybrids have been raised by crossing this species with other kinds. Some of the best are *Colchicus coccineus*, fine rich colour, brighter than the type *Commerzienrath Benary* (see page 643), white, spotted with crimson, a lovely variety. F. C. Heinemann, a spotted reddish-purple, and *Olban Otto*, white. These succeed under the same culture as the common Christmas Rose, and, as before said, their value lies in the fact that they considerably prolong the season of this lovely flower. However, when we think or speak of Christmas Roses it is the charming pure white flowered kind which flowers at Christmas that is uppermost in the mind. Although a well-known flower, it cannot be said that it is either extensively or well grown in gardens generally. It is ill adapted for plotting about in the sunny and oft-disturbed mixed border, but if those who desire to have its pure blossoms in quantity for personal, house, or church adornment at the great festival of the year, will only take a little trouble, and give the plants special culture in some suitable situation and well-prepared border, white flowers at Christmas, instead of being a scarcity, as now they too often are, will be profuse and plentiful enough for all purposes. H.

Rockeries in small gardens.—Rockeries in gardens of moderate size are usually sorry affairs, but they need not be, although, as a rule, even a well-constructed rockery is not seen to advantage in a small place. But where one is really wished for the first thing to remember is to have plenty of soil, avoid climbers, bits of china, and such like refuse. A few good stones, well laid, with ample soil between are sufficient, as the plants must grow, which is impossible where there is only a spoonful of soil for them to root into. This note is prompted by a rockery just constructed in a small garden, and it was found that the soil had sunk so that the stones were left practically dry, and the roots of the Ferns and the plants chiefly used without any soil whatever. In the spring when growth commenced—if it ever did—the results of such abominable planting would be soon evident. Rockeries under the drip of trees are invariably a failure, even when planted with Ferns, which do not like drip, although preferring moisture. Drip quickly destroys the beauty of the fresh green fronds. Far better is it to plant the space with border perennials, which make a show of colour if a judicious selection is made for spring until the autumn.

HOUSE & WINDOW GARDENING.

TULIPS AS WINDOW PLANTS.

EARLY Tulips make excellent window ornaments (see illustration). They do best when planted early in the autumn in boxes and placed in a dark cupboard or cellar, or in the open air covered with Cocoa-nut-fibre. As they come on for flowering, pot off, placing four or five Tulips

A "market" pot of Tulips.

in a small pot. This is a very popular plan in Covent-garden-market, where enormous numbers of them are sold. B.

Calla æthiopica "Little Gem."—Those who object to the ordinary Arum Lily on account of its height as a window plant, will do well to try the new dwarf variety "Little Gem," which is an exact miniature copy of the ordinary Arum Lily, and does well under similar treatment. If early flowers are required, then the plants should not be set out in the open ground, for as a rule those which are so treated do not flower so early as plants kept in pots.—F. B., *Winchester*.

TUBEROUS ROOTED BEGONIAS.

THESE are so largely used for bedding-out purposes, and have proved themselves particularly useful during a wet season, so much so, that most gardens will be using a few in future. In a wet season the Zonal Pelargonium is almost useless. Not so the Begonia, for although the fleshy flowers bruise easily, the slight drooping tendency they have, together with a fairly long peduncle, allows the flower to turn from rain sufficiently to avoid the complete shattering "Geraniums" and many others experience during thunder showers. In Preston Park (Brighton) I have seen grand beds of Begonias both during dry and wet summers. In Queen's-gardens, also on the front at Eastbourne and other seaside resorts, this flower does well. Even if we look at the other extreme, the London parks, we still find the Begonia one of the most showy and reliable bedding plants among large collections. Nor is it at all necessary to confine them to such purposes, as they are equally grand when grown in pots. All through early summer and autumn we find grand groups exhibited by the Messrs. Cannell, J. Laing and Sons, besides others too numerous to name. With these few opening remarks in support of the great and universal use of the Begonia, I will pass on to its culture, a note upon which will be more seasonable than might appear at first sight, seeing that now is the best time to sow seed, and which will, if properly treated, give us good serviceable plants for the ensuing summer, both indoors and out. There are four distinct methods of propagating the Begonia: From cuttings, leaves, seed, and division of their roots. Seed should be sown now (January), using a sandy compost of leaf soil and loam. Avoid peat; this does not suit seedlings so well as the leaf-soil, and has a tendency to produce drought and moisture at the surface. Care in preparing the pans is well repaid, good

drainage, with an even surface of rather fine soil, having much to do with the successful raising of seedlings. Thoroughly moisten the soil previous to sowing, as any watering until germinated is not advisable. A very small quantity of choice seed is certain to give much better satisfaction than the same sum expended upon a larger quantity from inferior strains. It is not absolutely necessary to sow in January—February and March are the times chosen by some—but when we bear in mind that early sowing will give us grand plants for the first season's use it is worth while taking the extra trouble. Never cover the seed with soil. A sheet of glass over the pan, and this darkened with Moss or paper until the seed has germinated, has proved most successful with me. Stand the pans in a heat of 65 degs. to 75 degs., and if they can be half plunged for a time, so much the better. This avoids the too early use of water, the soil keeping uniformly moist for a longer period. As the seed germinates rather irregularly it will be well to keep it partially shaded as long as possible without injury to those seedlings which sprang up early. The seeds not being covered with soil, they are easily injured by too much light being admitted prematurely; therefore, we must avoid this as well as the necessity for overhead watering until they are safely rooted into the soil. Under proper management it should not be necessary to water for some time; but when this becomes needful, stand the pan in water and let it absorb the moisture. Directly the forwardest seedlings can be handled, lift them out upon the point of a label, and place them in pans or boxes. Keep them in the same heat until settled to the new soil, after which they will be better on a shelf in ordinary greenhouse temperature. Later on they may be potted up into 3-inch and 4-inch sizes, giving them a little richer mixture when shifted into 6-inch pots. When intended for bedding purposes a partially spent hot-bed will suit them well. In this case I place a layer of loam, leaf-soil, and a dash of sharp sand over the bed, about 4 inches deep. Instead of potting the seedlings after they have made starchy little stuff in the pans or boxes, they are planted from these into the frame. Until the middle of May they can be growing freely, and it is easy to accustom them to more air by the planting-out season, say the end of June or earlier according to the season. A thorough watering before being lifted will ensure good balls of soil, and they are very little trouble when grown in this way. The other methods of propagation are need to increase a certain variety which is either valuable on account of its peculiar colour, size, or a combination of both. As many would doubtless like to increase some of their best seedlings I will touch as briefly as possible upon these methods.

CUTTINGS are readily rooted in the spring, and should consist of young growths taken off with a small portion of the old tuber as a heel. A very sandy compost, and care regarding water, will ensure success in a temperature of 65 degs. to 70 degs. It is also very interesting and easy to propagate from fully developed leaves. These are cut through their chief veins at a few places, and then laid upon a pan of sandy leaf-soil. As the cuts callus over they will form into small bulbs and root, eventually throwing up leaves and making a quantity of healthy plants. A brick bottom-heat assists this method largely. Division of the roots is an excellent plan when only a small increase is wanted, and can be best done in the early spring as young growths are starting. This will make it easy to divide them into pieces of more equal strength. There is nothing difficult in the culture of Begonias, and it has been fully treated upon in these pages more than once, therefore, I will confine myself to the above seasonable note. P. U.

Single Cactus Dahlias.—This is a new class of Single Dahlias, and not without beauty. The flowers are quite single, and they get their name "Cactus" from the distinctive twist in the petals, like the ordinary Cactus type. They are a charming race, as far as I have seen them, especially one variety, which, if anyone cares to get, will find useful for cutting. This is named *Guy Manning*. It grows quite 6 feet high, and produces a wealth of flowers, large, but not angular, and white, some with rose, the base

yellow. Its peculiarly soft pleasing colour, freedom, and elegance are its chief characteristics. There are other kinds in this group, but the colours are more of a rosy-purple and magenta type, which do not please me.—C. T.

ROSES.

NOISSETTE ROSES.

THE National Rose Society class these with the Tea-scented varieties, and from the great similarity existing between many from each section, as well as the complete mixture which seems to have taken place in the chief characteristics of the two sections, it would be well to lump the two classes in future. What is the difference between a Tea and a Noisette Rose? How often I am asked that question, and how difficult—nay, impossible—it has become to state the distinction in a definite manner. If I reply that the Noisettes bloom in clusters, and my attention is called to such varieties as Mme. de Tartas, Mme. Cusine, and others, which certainly flower in trusses to a far greater extent than many recognised Noisettes. As a second guide, I say that the Noisettes originated from a cross between the old Musk and the Common China, and developed a peculiarly strong, rambling growth. Still, the distinction is not sufficiently reliable. We have *Aimée Vibert*, *L'Idéal*, and *Maréchal Niel*, very good so far. But what about *Gloire de Dijon*, *Gloire de Bordeaux*, *Emilie Dupuy*, and others? Are they not equally strong and rambling in growth? Then my attention is called to *Caroline Kuster* and *Narcisse*. Where is the strong growth in the latter variety, one of the shortest-growing Roses we have? I have hewed these notes Noisette Roses, but I think we have already noted how mixed these two classes are, and to save the necessity of forming an intermediate class under the name of *Dijon Teas*, I think the N. R. S. did well to throw them together. It is better to do this than to create a new class. It is as climbers that this class of Rose shows to the best advantage, and I may name the following as particularly hardy and rampant in growth—Whites: *Aimée Vibert* and *Miss Glegg*. Yellows: *Rève d'Or* and *William Allan Richardson*. Reddish-yellow: *Fortune's Yellow*, *L'Idéal*, and *Bonquet d'Or*. I have not grown *Comtesse de Bouchard*, but I understand it is a decided improvement upon *Rève d'Or*. All of the above need pruning upon the long-rod system I have frequently recommended in these pages. P. U.

ROSES AND CLEMATISES.

I AM under the impression that I have previously drawn attention to the very useful and pretty combination formed by planting these two flowers, but as the time for commencing such a bed is with us, I propose naming a few Roses which are most suitable. All of them should be extra-strong growers, so as to be amenable to the pegging-down system, and to cover the ground without needing to be planted thickly. A second reason for extra strong growers lies in the fact that owing to the Clematis growth it will be impossible to remove the wood as soon as it has flowered, consequently, a great deal of the plant's energies will be withheld from the strong maiden growths issuing from the base of the Roses. With an extra vigorous variety we get sufficient growth of the desired character in spite of this seeming waste. It may be well to add a brief outline of how to combine these two most charming and varied flowers. Strong Roses should be planted at given intervals, say, 8 feet apart, if in a single row, such as on the outskirts of a lawn, by the side of paths, &c., or a distance of 6 feet each way if in a bed. A Clematis may be planted alternately with the Roses, when these will also be 6 feet or 8 feet apart. As each flower thrives well under the same treatment, if the following suggestions respecting pruning are carried out the result will be surprisingly pleasing. Late in the autumn, when Clematises are out of bloom, and the Rose-wood is more or less matured, cut away the wood of the latter which bore blooms during the early summer, leaving the uprights shoot ~~by which~~ ^{by which} ~~spring from the~~ ^{spring from the} base of the stool intact. In cutting away this

wood, you will naturally remove the Clematis growths at the same time, and the ground will be clear enough between the plants to allow of all necessary forking and manuring being done. This trimming out will also allow the plants more air, and tend towards sounder ripening of the Rose-wood. When the time for pruning Roses arrives, there will be very little to do in these beds except to dress over the ground as required, and to peg down the long growths as before, either to right and left if in single rows, or in such a manner as to most evenly clothe the ground should they be grown in a bed. The Roses will bloom very freely from midsummer until the first or second week in July, when their chief show will be over for the season, as these extra-vigorous growers seldom produce more than one good crop. It is here that the full benefit of the Clematis comes in, for if we plant varieties of the Jackmani type we shall soon be favoured with a gorgeous show of colour, and which may now be had in considerable variety. This class of Clematis makes strong growth and blooms upon the same during late summer and autumn. They are quite as hardy as Roses, but are more subject to the attacks of slugs during early spring, when young growths are pushing

from the bottom. For this I apply a dressing of soot and lime around the Clematis when pegging down the Roses. The Clematis shoots will intertwine among the Roses, and have a very showy and bold appearance all through the autumn. For all practical purposes the Jackmani Clematises may be considered herbaceous, and each season's growth can be removed with the superfluous wood of the Roses in the autumn. The following are all suitable for the purpose I have endeavoured to describe—*H. Perpetuals*: *Duke of Edinburgh*, *Duke of Teck*, *Engéno*, *Henry Bennett*, *Mme. Gabrielle Luizet*, *Margaret Dickson*, *Ulrich Brunner*, and *General Jacqueminot*. *Teas* and *Noisettes*: *Bonquet d'Or*, *Climbing Perle des Jardins*, *Emilie Dupuy*, *Gloire de Dijon*, *Henriette de Beauvean*, *L'Idéal*, *Reine Marie Henriette*, and *William Allan Richardson*. I also like the following, chosen from various other classes: *Ghêre Lyonnaise*, *Belford Belle*, *The Waltham Climbers*, *Mme. Isaac Perier*, *Blauche Moreau* (White Moss), and the *Austrian* and *Persian Briers*. It is not necessary to name the Clematises, because all in the class I have recommended are about equally suitable. P. U.

PANICUM VARIEGATUM.

WHERE indoor decoration has to be provided plants of a trailing or pendulous habit of growth are necessary for furnishing the edges of jardinettes or stands, and this is an invaluable plant (see illustration) for the purpose, its habit of growth and beautiful variegation being in every way perfect. I insert three cuttings in a small pot, and as soon as they get a few inches long, peg them down close in the soil, when they throw out a number of side-shoots, and form excellent plants without any further training. J.

A hardy foliage plant.—A foliage plant in winter is the Common Helleborus (Fetidora), a native of England, and too little seen in gardens. It is worth planting for the sake of its fine leafage also, this being of a pale deep-green colour, leathery, abundant, and forming bold tufts, so to speak, quite as rich and ornamental as many things grown in stoves for their foliage alone. Early in the spring one gets the greenish flowers produced in abundance, and in association with the dark-coloured leafage are pleasing. A clump of this Hellebore on the rockery at the end of the border is a feature in the garden in winter. C. T.

FERN.

REPOTTING FERNS.

Now that we have a new year with us most of our greenhouse occupants will be needing an overhaul, more especially the Ferns. A few things which may be done and a few which should not be are what I propose incorporating in this article. One of the most important points in potting Ferns is to wait until they are just moving into new growth again. We want the roots in such a state that they will take to the new soil at once. Without this we get a stale compost very early, and it is seldom advisable to water them until their roots are well into the new soil. A too free repotting, or too large a shift is also less beneficial than a slighter one; and the annual repotting of these favourite plants was responsible for many indifferent results. A plant which is tightly root-bound, may be improved by repotting, but when barely filled with roots they do not appreciate disturbance, provided the soil is well drained and suitable. Of all the vast number of Ferns now in cultivation, the Maiden-hair (*Adiantum cuneatum*) is far more popular and numerous than any other. I find it an excellent plan to cut down the whole body of fronds from a few of the shabbiest-looking plants, stand them in a warmer temperature until new fronds are moving freely, repeat those needing it, and keep them in the warmer quarters until the new fronds are almost developed. If a small stock of plants are looked over and then treated thus in two or three latches, we shall soon have a nice show of healthy and well-furnished stuff. Some Ferns, the Maiden-hair among them, may be divided when potting, but I like all Ferns best when raised from spores. In a general article of this nature it is not possible to give the best compost for a large number of genus and species, so I can only name one which is suitable for almost all Ferns. The fibrous turfy loam so generally recommended for all pot work is the very best loam you can have for these plants; but it is difficult to get in many localities. In that case get the nearest approach to it you can. I know an amateur who cuts up pieces of turf by the roadside and stacks for his small collection. Not many years ago it was considered necessary to have peat for Ferns, but I venture to say that less than a quarter of this is used for the same purpose in the present day. Still, we do not want to forego peat entirely. Turfy loam, peat, and leaf-soil in equal proportions, with a dash of sharp sand, will be grand for almost any species of Ferns. Mix these thoroughly, and have the whole just moist enough to allow of firm pitting, without "cakiness" or drying hard, as if the compost had once been mud. Never pot into soil of less temperature than the Ferns are growing in. Non-attendance to this has caused many disappointments, nor can this be wondered at when the roots of a plant just pushing into fresh activity are immersed in a compost some 10 degs. to 20 degs. colder than it already occupies. To make the soil firm around the ball of a plant which has recently been occupying a pot almost as large needs care. Add a small portion of soil at a time, and ram this down fairly firm with a stout label or potting-stick. Unless this part of the operations be done properly water will percolate through the new soil too freely to allow of any moisture reaching the old ball without an undue amount being supplied, and there are few things in the culture of Ferns more injurious than this. Drainage is another item which needs attention. As a class, amateurs look upon Ferns as needing a good quantity of water; this is often overdone. With a few exceptions we do not find Ferns growing in wet soil while in their natural state. If we pass over the *Osmunda* we do not find any of our own varieties growing in wet soil; they are in sandy loam, and generally upon a bank. A dry, arid soil does not suit them any more than a wet one; what we want is a quick drainage with a soil of that medium moistness spoken of as cool. One or two good crocks fitted over the drainage hole with care, and then a small quantity of cinders on top of these will provide safe drainage, with the loss of little time and trouble. Shake away a good bit of the old compost, use clean pots, and a good exposing the roots for any length of time.

TRUE MAIDEN-HAIR FERN.

This pretty hairy Fern (*Adiantum Capillus-veneris*) is admirably suited for cool houses. I have seen it thrive luxuriantly on walls on either side of such a house, and it is admired by all who see it. In a plant-house at Hammersmith I once saw it growing well; it is grown on a wall about 3 feet high, which is thickly clothed from top to bottom with its beautiful fronds. Being a surface-rooter it is better adapted for this kind of ornamentation than most other varieties, and when grown in this way it is, in

Fronds of True Maiden-hair Fern.

addition to having a fresh and dressy appearance, most valuable for cutting for bouquets, &c. If the fronds, when they begin to get shabby here and there, are cut off, a constant succession of fresh young fronds may be obtained.

LOXOGRAMMAS.

I HAVE some dried fronds of this Fern from "W. M.," which he says he received from the Neilgherry Hills amongst some Orchids. He has pegged the rhizomes down, and he thinks he may get some of them to grow, and he wishes me to say a few words about them. The names of the species is *L. involuta*, but I can scarcely say anything about the plants belonging to this genus in a cultural manner, because this is a genus which I have never seen in a living state; but from the specimens which I have, I should imagine they would be very interesting and handsome Ferns, and many a time have I received rhizomes of these plants home by post, but I never could induce one to grow. These are Indian Ferns, which appear to come near to *Antrophyum* in their manner of growth, but they differ from them in forming linear sori, which cross the junction of the little veins, which are hidden in the leathery texture of the fronds. I have tried to grow these plants by affixing the rhizomes to the Orchid blocks, but in this place never succeeded in getting them to grow. I also have pegged them down on some Orchid peat and placed them in the cases with Filmy Ferns, and here I got several to start growing, but they soon died. I imagine too much moisture and too close an atmosphere was the cause of this failure, and I am not aware that they have been successfully established in any gardens in the country; if so, I should like to hear from the parties, having them. The following kinds are the best known; there may be many more species, but as great differences of opinion exist as to what constitutes a species, and we have not yet included them amongst our garden plants, I will leave them with the heartiest wishes for the success of "W. M." in his undertaking. These plants, although natives of India, all of them, grow at from 2,000 feet to 7,000 feet elevation, so that they do not require great heat.

L. INVOLUTA.—This is the plant sent by "W. M.," and it is a somewhat common Fern in many parts of India. It has a stout creeping rhizome, which bears fronds some 12 inches or 18 inches high, and 1 inch to 2 inches broad. These taper at both ends and bear linear cross sori, which spread outwards from the midrib, and are leathery in texture, and pale green in colour, smooth on both sides.

L. LANCEOLATA is a very similar plant to the last named, the rhizome is creeping and the fronds seldom exceed a foot in height and an inch in breadth, and the sori are more oblique, often, indeed, parallel with the midrib. They are coriaceous in texture, smooth on both surfaces and of a rather deep-green in colour.

L. AVENIA, another pretty species, but less coriaceous in texture; its rhizome is creeping, and they grow to some 18 inches in length. They are broader than the other two kinds, but taper gradually to the base. The sori are numerous, in oblique lines not touching the midrib, and falling short of the margin. This comes from the Midny Peninsula and the Malay Islands.

THE KITCHEN GARDEN.

STRONG TOMATO-PLANTS.

THERE seems to be a prejudice against strong young Tomato-plants. At one time they were objected to because it was thought those less vigorous were not only the first to produce fruit, but were also the heaviest croppers throughout. Some old-fashioned gardeners did not believe in seedlings, being under the impression that these were far too strong growing to become quickly and heavily productive, and in order to counteract this supposed unfruitful habit of growth it has fallen to my lot to have to strike the tops of strong seedlings and to throw the plants or stumps away. Even in those days, this being when Tomato growing under glass was in its infancy, I felt that this was so much wasted labour, and nearly lost my situation because I protested against striking the tops a second time. Cutting-raised plants are not one whit more precocious in producing fruit than are seedlings, nor do they, as a rule, fruit any nearer the ground than do those raised from seed and properly prepared. When the scare caused by the new form of disease most generally known as *Cladosporium* was at its height, one preventive measure to which much importance was attached was the preparation of extra hard-stemmed plants, subsequent culture also tending to keep them from becoming so vigorous as they are apt to do when planted out in rather strong soil. Undoubtedly, the disease does act most fatally in the case of Tomato-plants in a luxuriant condition, more especially when this is brought about by means of a rich root-run, strong heat and moisture-laden atmosphere, but though it is most advisable to avoid the latter error, it is not wise to start with stunted plants. Stunted plants too often mean legginess, the hard stems also failing to ever swell properly. By far the most profitable plants are those which produce a strong first cluster of fruit, this reaching down so as to nearly or quite touch the ground; whereas, in the case of starved, leggy plants the first bunches of fruit are both feeble and formed from 18 inches to 2 feet from the soil. I hold that Tomato-plants should never be placed in small pots. Once they become in

THE LEAST BIT UNDER-MIND the growth is spindly and weak, and is with difficulty recovered to a more robust state. The seed should be sown thinly in pans or pots filled with fine sandy soil. This sowing is recommended because the seedlings if crowded quickly weaken each other, and there is no sense in raising very many more of them than are needed, while fine light soil ought to be used, as it is only out of this that the tender young roots can be shaken or lifted without experiencing a severe check. Tomato-seed germinates very quickly and surely in a brisk heat, and directly the seedlings are well through the soil they ought to be raised more up to the light, a shelf near the glass suiting them well. When well into the rough leaf they should be potted off. Prepare a heap of light loamy compost, and warm this thoroughly by means of heated bricks plunged in it. The pots to be used ought to be either 5 inches or 6 inches in diameter, clean and lightly drained, and the potting should be done in the house where the seedlings are growing, a few minutes in a cold potting-shed checking them badly. Place a little rough soil on the drainage and fill up to the rim with the soil. The seedlings should be carefully shaken clear of each other, and be then sunk up to their seed leaves singly in the smaller sized pots or in pairs against the sides of the larger ones, strictly jarring down the

soil being all the fixing needed. Place them in a warm, light position, shade from sunshine, and water gently if the soil is at all dry, watering somewhat sparingly afterwards. Directly the plants have recovered their healthy colour expose them to the full sunshine and raise well up to the glass. It will not be long before they commence rooting—the buried stems freely emitting roots—and growing strongly, their sturdiness being most marked. If kept long enough in these pots for the first bunch of flowers to be well developed, the stems will soon begin to elongate unduly, and the final putting or planting out should be done before a root-bound state is arrived at. There is little or no likelihood of plants thus well prepared failing to show strong bunches of flower before they are 12 inches high, and it will be largely the fault of the cultivator if they subsequently fail from disease or other causes. Now is a good time to sow seed if an early crop of Tomatoes under glass is required, but for greenhouse and open-air culture from the middle to the end of March is quite soon enough to raise plants.

W.

FORWARDING EARLY PEAS IN POTS.

There cannot be any question as to errors of culture in this phase of Pea management, and the truisms, the more haste the less speed, is very evident in the raising of early Peas in pots. Now that the practice of sowing Peas in November or December is not practised so largely as in days gone by, many people appear to be in too much haste at the turn of the year to forward them as much as possible by sowing in pots and boxes and placing them in heat, with the result that they become drawn and tender, and also very much pot-bound. Economy now being the order of the day, it also has to be extended to the seed list, and if no more seed of the earliest Peas were ordered than would be sufficient for a first sowing, and these should have happened to have been sown in heat early in the year, it is very evident the plants would be poor when a reasonable planting time arrived. It having now become the practice to rely for a first crop on the dwarf earlies, such as Chelsea Gem, William I. and English Wonder, these are not so apt to show outwardly the ill effects of early sowing, like William I. for instance. Being dwarf growers, they do not grow very high whilst in pots, or at least not much above a couple of inches, but the pots will be filled with roots, and after the plants are set out they grow but very little afterwards—in fact, many people are often surprised at their showing for bloom when only a few inches high. The taller growers will become spindly and fall about, and very often need sticks for their support before it is safe to plant them out. By not sowing the seeds before

the end of January or the first week in February, the conditions by planting time will be quite different—that is, of course, if not hurried on in heat, as even at this time there are ample opportunities for their becoming spoiled if this latter practice is indulged in. Being brought on under cool treatment, the plants grow along sturdily, so that they are in fine condition for planting. Even if inclement weather should occur afterwards they are not likely to receive much of a check, and with the return of fine weather they grow away freely and strongly. I look upon small pots for sowing the seed in as an evil. I have always been an advocate for sowing in 5-inch pots. Whenever the weather and soil are in a suitable condition the Peas are planted out. If they are dwarfs, they will well repay the shelter of a warm south border. These early south borders generally have extra attention bestowed upon them in receiving additions of other material, as as to make them as fertile as possible. A dressing of well-prepared manure and wood-ashes should be applied in all cases where support is needed. In planting, turn the plants out of the pots carefully, and set them 6 inches apart in the rows, drawing some of the best soil about the balls, also seeing that it is well pressed about the roots, this assisting the plants to take readily to the soil. After the Peas are planted draw the soil up on each side as a means of protection, at the same time placing some short straw sticks round them. Some people, I know, claim to be

waste of time to place sticks to dwarf Peas, but the advantages far outweigh any supposed disadvantages. A.

TWO GOOD WINTER VEGETABLES.

It is an easy matter to have plenty of vegetables during the summer and autumn months, but this is not so from November onwards. To meet this demand I grow a large breadth of *Couve Trenchuda*. This I find most useful from October onwards, and it is much sought after by the cook. When the heads are large and the leaves have big midribs, then it is that it does us good service. In my case only the midribs are used and dished up like *Seakale*. To obtain the best results I find it best to sow a little seed under a lamplight early in the year. Some people complain that this Cabbage is not hardy. Be this as it may, I find it as hardy as other Cabbage. After the heads are cut I find many of the stumps live through the winter and give some beautiful tender greens all through the spring. *Chou de Burghley*, although severely commended by many cultivators when first sent out, is also valuable when it is taken into consideration how hardy it is and that it comes in from the beginning of the year onwards, and that the heads are very white and tender. To have it in this state and at this time I sow it at the same time as *Broccoli* and plant at the same time. At the present time (Jan. 3) I have a fine lot growing on a piece of land from which *Strawberries* had been cleared. F. A. C.

NEGLECTED VEGETABLES.

SALSIFY AND SCORZONERA.

The first-named vegetable, when well grown, should be crisp and white in flesh, like the Parsnip, and it requires a deep, rich, and well-pulverised soil that has been well manured for some other crop the previous year. The seed should be sown the first week in April, in drills drawn 1 foot apart, and it should be dropped into them thinly. After the plants have appeared above ground they should be thinned in the rows to about 9 inches or 1 foot from each other, and the ground should be kept well

A market bunch of Scorzonera.

surface-stirred and thoroughly clean all through the following summer. The return for this attention will be the production of a good crop of long, clean, straight roots, often as large as a moderate-sized *Surrey Currot*. Although a useful and excellent vegetable that has been long known and used in this country, it is not nearly so much cultivated as it deserves to be. It is admirable served up to table as a second course with white sauce, throughout the autumn and winter. It is one of the most valuable

substitutes for the Potato, and a heavy and weighty crop can be produced from any kind of soil. A few rows sown in an odd corner would produce many a good dish of wholesome food throughout the winter. The roots can be taken up in autumn and stored as Parsnips or Carrots are, or be left in the ground and mulched in winter. When lifting the roots care should be taken not to injure them in any way, as they quickly bleed, and loss of flavour to the root is the result. *Scorzonera* is grown for the root, as in the case of Salsafy, but the root has a different appearance, inasmuch as it grows longer and more slender than Salsafy. It is also more apt to run to seed. They are both worked in the same way, and the mode of culture recommended for Salsafy will answer perfectly for *Scorzonera*. B.

SOWING PEAS IN POTS.

At this season there are various means adopted to secure a few dishes of Peas in advance of those sown in the open ground early in the year. I am fully alive to the fact that Peas sown outside at the end of November or early in December will give a few early dishes, but on heavy land it does not pay. A sheltered border is also necessary, and there is continued warring against mice and birds before a crop can be secured. I am aware that sowing in pots causes a certain amount of work, but it gives a fair return, and a good dish of Peas is always appreciated. I do not like sowing Peas in pots in strong heat a month or six weeks before they are wanted to plant out; I believe this to be the cause of many failures. In the case of Peas sowing may take place towards the end of December—that is, if the plants can be given a warm border in March. I usually sow from the 18th to the 30th in cold frames, using 5-inch pots and not sowing too thickly, also using good loamy soil not too light, as if at all light and porous the roots do not take such a firm hold. Some fine or lighter soil may be used for covering the seed. If the soil is damp, one good watering with tepid water at the time of sowing will often be sufficient till the seed has germinated. It may be objected to that early sowing causes weakness by the seed being so long in the pots before planting out. Such is not the case, but the reverse, as the growth is slow at the start, and therefore when the seed has germinated, the Peas are as good as those sown in the open in March and above ground in April, and being raised without heat there is no fear of collapse, provided due attention is paid to moisture and keeping as near as possible, and giving free ventilation by removal of lights in favourable weather. It will also be observed I recommend larger pots than is usually employed, thus allowing more root space, also good loam in place of leaf-mould, this adding to the strength of the roots and tops. Early Peas raised in this way suffer little injury if planted at the time named. Cold east winds are more harmful, but these may be minimised by placing branches with the foliage on to break the wind, also by drawing up the soil against the plants and well firming the ground when turning out of the pots. The variety to be sown is also important. I do not think it necessary to sow the small round White Peas in pots, as though a few days earlier they give a poor return. Of course, if earliness is the important point, they are valuable, and even when this is not essential, a few rows planted out as advised will give a dish or two in advance of the wrinkled kinds. For general cropping, *Chelsea Gem* is in advance of other kinds, and when sown in pots can be had fit for table the first week in June. I would also advise a trial of the larger Peas, such as *Duke of Albany*. They do equally well, and though termed second early, are but a few days behind the earliest. Last year I sowed a fair portion for use on June 10. When sown for early work they are much dwarfier, not more than 3 feet; indeed, I topped some 2½ feet, and when grown thus there is little trouble with stakes. The pods being fine are much valued so early in the year. C.

3172.—Cooking vegetables.—When cooking green vegetables my cook always puts a quarter of a slice of bread on the bottom. There should never be any smell, so we prefer a piece of toast placed in a muslin bag.—177

A NOTE ON BRETROOT.

Act. things considered, Dell's Crimson is the best Beet in cultivation, and as a consequence the synonyms are particularly numerous. The former may be purchased say at the rate of 1s. per oz., but when the seedsmen honour (?) it with his own particular patronymic, then the price goes up another 6d. Unless I am greatly mistaken the rage for novelties in the way of vegetables is less pronounced than formerly, and the time may not be far distant when the well-tried old forms will be most preferred, the glowingly described and presumably new and distinct forms being taken little heed of. My advice to those who have found a variety of Beet that grows well on their particular soil, the roots being of medium size, well formed, richly coloured, tender and sweet when cooked, is to grow no other. On our rather strong soil, Crimson Ball, a good form of the Turnip-rooted, is the best for early use, but by far the most space is devoted to Dell's Crimson. The latter may be sown early in April without much risk being run of the roots becoming coarse, though I find the end of the month or even early in May answers better. In the case of Pragnell's Exhibition, early sowing would result in the growth of roots more resembling Mangold than Beet, and in most seasons the roots are too large, even when late sowing is resorted to. Exhibitors naturally favour large roots, and while this rule holds good Pragnell's variety will be most shown. Cheltenham Green-top and Omega also grew too large each time they were tried here, but all three might yet give satisfaction in other gardens. Crimson Ball would be the best for shallow ground resting on gravelly, but subsoils. I could, if so disposed, give a fairly long list of what I consider synonyms of the best types, but am of opinion that this should come from "head-quarters" or where there is the least likelihood of mistakes being made. H.

5257. **Cabbage for show.**—Seeing that the best prizes are frequently given to Cabbages that are so large that they are only fit to feed cattle, your question is much more difficult to answer than many people would suppose. Personally, I should prefer a rather small Cabbage, such as the Little Pixie. Wheeler's Imperial is somewhat larger, and when well grown very suitable for exhibition. For a Red Cabbage you may select the ordinary sort. You must, however, obtain plants raised from seed sown in the autumn, as unless you get heads large enough to require a wheelbarrow to take to the show, you will not please the majority of our judges at vegetable exhibitions. The White Cabbage seed may be sown in March, and the plants put out in well manured ground and given plenty of room. The best Cauliflower for exhibiting in August is Veitch's Autumn Giant. You cannot, however, depend on it to heart in time from spring-sown seed in the open. If you can raise a few plants under glass by sowing the seed in February—even if it is a wood frame—you will be safer, as to obtain heads that will be large enough to stand a chance of winning a prize, the plants must be unusually strong, like the Cabbage, the Cauliflower must have rich deep soil and plenty of room. I. C. C.

— Wheeler's Imperial is a good variety, so also is Carter's Heartwell. Seeds sown middle of August, left in the seed-bed all winter, and planted in April will not be far out; or seeds may be sown in a box under glass in February and planted when ready in good sand. The Blood Red is a good Red Cabbage. The most reliable Cauliflower in August is Veitch's Autumn Giant, but it must be sown early. I always sow in autumn; but a few seeds sown in heat in February will be time enough. The Wheeler is a good Cauliflower for August on a cool border. E. H.

5248. **Pea and Bean for show.**—The largest and most taking Pea for show in the month of August is undoubtedly Jubilee. You must, however, understand that in the case of Peas it is not always the largest that obtains first honours. It is those that are in a fit condition for table that more often than not decide the question of merits in the month of August, as it is sometimes difficult to get a good and

dish of Peas at that time. For that reason you must plant the Peas 3 inches apart in deep-dug and well-manured ground. You had better make one planting about the middle of April, and another three weeks later, so as to extend the time of bearing. The best Runner Bean is the Champion. This has thick, handsome pods which for table quality are far preferable to those sorts which have wide and longer pods. The beginning of May is soon enough to plant Runner Beans. Dig out a trench 9 inches deep, then put in the bottom 4 inches of rotten manure, and put half of the soil back on the top of it, and set the Beans 9 inches apart in the middle of the trench.—J. C. C.

— Culture has something to do with it. Duke of Albany is a good Pea; Sutton's Giant Emerald Marrow also comes out well. These large-podded varieties which do not fill up till the pods lose colour are not of much use. For the same reason I do not care much for the Seville Long-pod Bean; it is difficult to trim it right. The Giant Long-pod, although not so large, is more reliable. Hardie's pedigree Windsor is a good Broad Bean. Both Peas and Beans should be sown by the middle of April.—R. H.

5249. **Growing Cucumbers and Melons.**—These can be grown very well in flower pots; indeed, almost, if not quite so well as by "putting loose soil on the stage" to grow them in. The best way to grow them is not to plant them from, say, a 3-inch or 4-inch pot into the one the plant is intended to fruit in, but repot from a 3-inch or 4-inch into a 7-inch; from that into a 9-inch, and ultimately into a 12-inch, in which they will bear their fruit. They both require good soil, Yellow loam three parts, decayed manure one part, and an 8-inch portion of powdered lime. Put freely, and leave 2 inches upon the surface to be removed by surface-dressing; that is, at the last potting the soil ought to be 2 inches below the rim. This space may be filled up when the fruit is formed with a compost of equal parts manure and manure.—I. D. R.

— If you are growing stove plants in the structure you allude to, you will not be wise in attempting to grow Melons in the same house. I do not say it cannot be done, but as Melons require a dry air when the fruit is ripening to bring up the flavour, you will run the risk of getting your flowering and foliage plants infested with red-spider, which every good gardener regards as a deadly enemy. You may grow a Cucumber plant or two early in the season without much risk, but if you value the permanent occupants of the house you will root them out by the middle of May. Lockie's Perfection Cucumber is a capital sort to fruit in pots, and if you put one plant in a pot 16 inches in diameter, and well feed the roots as soon as it begins to swell off the first fruit, you may obtain a fair supply up to the time that you may get them in a warm frame or pit. I have many times had good crops of Melons from pots of the size above mentioned, with the growth trained along the front of a Pine stove; but the air of a fruiting Pine-house in the months of July and August is generally much drier than that of an ordinary plant stove.—J. C. C.

— Both these may be grown in pots from 11 inches to 15 inches across, but, of course, in this way they require greater and more skillful attention in watering and feeding than when planted out. Melons especially often do remarkably well in large pots of good sound loam, not too rich, and made hot; but Cucumbers require a richer and lighter soil and more liquid manure.—B. C. R.

— These may be grown in large pots, say 10 inches or 15 inches over. Leave space for top-dressing, and give liquid manure when required. Both Cucumbers and Melons have been well grown in pots. Requires more care.—E. H.

5243. **Potatoes for show.**—Two excellent kidney Potatoes for exhibiting are Snowdrop for the early shows, and Satisfaction for the later, both varieties of handsome appearance, and used more than any other kinds for this purpose. Reading Bunch, of the round kind, is good. It is red, and a very fine exhibition variety, whilst Beauty of Hebron is also useful for shows.—C. T.

— As a white, round Potato, including to the pebble shape, Satisfaction (Sutton's) is one of the largest and most handsome varieties that ever grew. Good examples of white Beauty of Hebron will be hard to beat in the kidney class; but if the highest form and finish is desired, the International Kidney or Sutton's Perfection would be preferable.—B. C. R.

— Windsor Castle, White Round, and Snowdrop, with Kidney are good varieties, not only good for show, but good for the table.—E. H.

FRUIT.

PRUNING AND DRESSING VINES.

The fruitfulness of the Vine has long been a proverb—in fact, if we want to describe or illustrate fertility, the Vine is pretty sure to be selected for the illustration, and a perfectly true one too. For under any sort of culture it will at least put forth any number of bunches, even though it be quite unable to perfect them; but there is a vast deal of difference in the size and kind of bunch that Vines will produce under different kinds of culture. But what I want especially to bring home to your readers is this—viz., that there is a great deal depends on the mode of pruning as to whether the bunches will be numerous and fine of their kind, or whether they will be less abundant and small of their kind. Now, I think it is pretty generally conceded that the spur system of pruning is the best for the majority of varieties of Grapes; and by the spur system I mean single rods allowed to extend, more or less rapidly, until they reach the top of the bunch, and the side or fruiting branches cut in every year to one or two eyes, the number of years it takes to furnish the house from base to summit depending a good deal on the strength of the Vines. Under this system excellent crops are produced for several years; but, as a rule, after ten or twelve years' hard cropping the bunches, although they may continue to be as plentifully produced, will gradually get smaller, which is only a natural consequence of the spur getting thinner, and the sap flowing more freely into the younger wood at the extremities. The same thing occurs in other fruits, notably in large standard Apple-trees, the finest produce being invariably found on the young wood at the extremity of the branches, and then the question arises—How are we to replace the old rods without the loss of a single crop of Grapes? Well, I find the best plan is to take a few young rods from the very lowest part that can be got, and train them for the first year between the permanent rods, keeping them close up to the glass, so as to get the wood well ripened at the next winter's pruning. They will be cut back according to their strength and ripeness of wood; and the rod which they are intended to replace is not cut out at once, but all the old spurs are cut down off to the height of the new rod, which is trained over it, and the top spurs are allowed to fruit for another year or two, or until the new rod has filled the space with new wood; and it is surprising how much the Vines, even if quite old, appear to be strengthened by the laying in of young wood. Some kinds of Grapes, such as Barbarossa, will become almost barren unless young wood is introduced, and all are greatly benefited thereby. Pruning should be finished by the end of the year, for bleeding is caused by late pruning. Clean the rods at once, and dress with some kind of insect destroyer that is safe and sure; one of the oldest and best is Gishurst Compound, for it destroys insect life and does not injure the limbs. Anything of an oily nature is dangerous in our hands because of its not mixing with water readily. Many Vines are spoiled by careless dressing. JAMES GIBSON, Gosport.

Canker in Apple-trees.—Canker in Apple-trees is, I think, very much aggravated by the conditions of the soil and the manner in which the trees are managed. Some varieties are much more liable to canker than others. It is idle to say that all sorts of Apples will grow in any soil, no matter how favourable the situation may be as regards the climate, shelter, &c. I have here many instances of this. Rilonston Pippin as a standard, Scarlet Pearnan as a bush, and Gloria Mundi grown in the same way exemplify this too well. The first has been planted fourteen years, and during that time the tree has been planted at least three times in various kinds of soil; the stem is thicker, of course, but the head does not cover a bit more space now than it did when first planted. Growth has been made at times freely, owing to the change of soil, but the succeeding winter has laid the foundation of canker, which was fully developed the next season. Many examples might also be quoted of trees that showed decided signs of canker at one time, as the result of deep planting, but of a system of too close cropping. The constant adding to

the soil of manure and other materials raised the soil about the trees so much that the roots were deeply buried, canker in the branches quickly following. The spread of this was checked directly the trees were lifted, their roots brought nearer to the surface, and instead of the ground between the trees being cropped with vegetables, it was laid down to Grass. Soil that is heavy, therefore retentive of moisture and consequently cold during winter and spring, is conducive to canker in some sorts of Apple-trees, particularly if the roots are deep and away from the influence of the sun. Shoots that are not ripened owing to the causes above named are almost certain to be affected with canker. With such a large number of varieties, it is possible to make a selection suitable for any soil, but the difficulty is to know the offending sorts when making the selection.—E.

GRAPE FOR A COOL GREENHOUSE.

The Chasselas de Fontainebleau Grape may be seen in the Paris markets, packed in small boxes or circular baskets. This variety is not unfrequently grown as an early Grape in this country, under the name of the Royal Muscadine; but it is not so delicious when forced in our hot-houses as when ripened under warm sunshine on the white-washed walls of Thomey and Fontainebleau or St. Cloud. There are several varieties of Chasselas grown in French gardens, all of which are of excellent flavour; but this is the best of them, and the one most generally grown, as a desert Grape, for the French markets. The Vine is moderately vigorous in growth, and is easily recognised, even when not in fruit, by its peculiarly blunt-lobed rounded leaves. The bunches are generally small, rarely exceeding a pound in weight, even when grown indoors in this country, and grown out-of-doors in French gardens the clusters are smaller still. The berries are round and of a clear greenish-yellow colour, acquiring a pink or amber tint on the sunny side when fully ripe. Being of a peculiarly sweet, juicy flavour, and producing a crackling sensation when eating, it seems singular that this delicious little Grape does not more frequently find its way to our London markets, as it can be imported quite as cheaply as the Spanish Chasselas and Sweetwaters, and it is greatly superior to them in flavour. It bears packing and carriage well, and the only drawback is that it must be sold as soon as it is ripe, as it does not keep longer than a week after being cut, and this is, doubtless, the reason why our London fruiterers do not care to import it. As brought to the French markets, the bunches are wedged tightly into oblong deal or Poplar wood boxes, without any packing, each box holding from 3 lb. to 5 lb.; and, in fruitful seasons, these boxes may, as a rule, be bought at prices varying from 2s. to 3s. each. It is an excellent Grape for a cool greenhouse.

B.

PRUNING NEWLY-PLANTED APPLE-TREES.

SOME writers advise that newly-planted trees ought not to be pruned the same season as planted; others, again, say that instead of cutting them hard back, the points only should be taken off. My experience leads me to say both these plans are wrong, as I will endeavour to explain. Take, for instance, a standard Apple of any variety, but, for the sake of argument, suppose we name Beklinville, which is one of the best sorts for this form of growth. If the tree is not pruned the first year, but cut hard back the second, we lose a whole year's growth. The argument against pruning the same season as planting is that it is unwise to give two checks to a tree at the same time. The tree received one at its roots when being planted, and to cut the branches would be giving a second. The fallacy of this reasoning is easily shown. The tree, in the weakened state through

planting, has not the power to push growth from all the buds the shoots contain. The sap, as a natural consequence, rushes to the tips of the shoots, a weakened growth being produced by the extreme eyes, while those buds nearest the base of the tree remain quite dormant. The result is that the tree at that part always has a bare stem. Now, if the tree had its weakened energies concentrated into a limited space of say 6 inches or even 8 inches in strong shoots, a much more satisfactory growth could be expected the first year. The plan of cutting off the points of the shoots, say a couple of inches from each, will result in only a few inches of new growth being added—perhaps a couple from the stronger and hardly any from the weaker ones. Several eyes at the base will remain dormant, while those that do push at all, with the exception of the leading one, will form fruit-buds. I suppose it will be allowed by all that the first object in a standard Apple-tree is to encourage growth, and not the formation of fruit-buds at so early a stage of the tree's existence. The simple topping of the shoots does that which is not required—the

FORMATION OF FRUIT-TREES instead of a free growth. The following year even these premature flower-buds will expand and probably set fruit, thus again weakening the growth of the tree. The proper method then that I consider gives the best results is to cut the shoots back

Grape (Royal Muscadine) Chasselas de Fontainebleau.

to within 6 inches of the base in the case of weakly grown trees, allowing a couple or so more inches to the stronger, selecting, of course, an outward bud to cut to as being the best means of maintaining the desired shape of the tree. The result of this pruning will be that shoots from 1 foot to 2 feet will be made the first year, thus laying not only the foundation of the future tree as regards its proper clothing with branches from the base, but providing space for a full crop of fruit in a few more years. The first year should surely be devoted to the encouragement of growth. Of course, much will depend upon the manner in which the trees were planted and how they are managed the summer following the pruning. If they are allowed to suffer from want of moisture at the roots in consequence of a scarcity of mulching material or a scarcity of water, growth like that named will not be forthcoming. All newly-planted trees ought, however, to be mulched the first year; it not only saves time in watering the trees, but it keeps the roots cool and moist during the hottest weather. When the soil is dry it cracks, and allows what little moisture there is to escape by the action of the sun upon the soil drawing up the moisture through the cracks. The early part of February is a good time to prune newly-planted trees; no matter whether they be standards or bushes, the treatment should be the same in this respect. The only point of difference is that the shoots cannot always be cut to one-third length as in the case of standards.

some branches on the bushes require a greater length of shoot to be left in some parts to give the tree the necessary shape. F.

BLACK CURRANTS.

WHEN well grown, the Black Currant is not only one of the most useful of fruit, but also one of the most remunerative. Of late years some growers have had a serious evil to contend with—viz., the Currant bud mite. Bushes or buds affected are easily noticed in the early spring, the buds having a rounded or swollen appearance instead of bursting out into leaf. The remedy for this is either to pick off the swollen buds and burn them or cut off the affected shoots. Syringing the bushes in the autumn with some insecticide is also resorted to as a safeguard. Happily, however, this pest is only local, so that it is within the grower's power to stamp it out. The Black Currant will succeed well on almost any soil and situation; it has also its likes and dislikes in this respect. For instance, in the West of England it may be seen thriving to perfection in the valleys of the Severn and the Teme. I have often been struck with the growth there made, the annual shoots from the bottom partaking more of the character of Willows. The above proves that the Black Currant is a gross feeder, and where it does fail, it must be for the want of adequate support or faulty pruning. The worst soil to contend with is a stiff clay, but even on this the bushes will succeed well if attended to as regards rich top-dressings. As regards

PRUNING, all that is necessary is to thin out any old bearing wood to allow room for the younger, which should be encouraged to grow right from the bottom. In the case of the Black Currant, all the lower buds are retained when the cutting is made, so that the future bush will partake of the character of what is termed a "stool." To produce a good stool, the bushes after planting should be cut down to within 2 inches or 3 inches of the ground level. I have renovated old bushes by completely cutting them down to within a few inches of the ground-line, and with the assistance of a good dressing of manure and burned garden refuse the after-growth has been remarkably strong. The burned refuse and manure form good material for top-dressing, which is very important, merely laying it on the surface to the depth of 2 inches, not forking it in in the least. It is not often that time can be afforded to apply a soaking liquid-manure or sewage, but where it can be given, there cannot be any question as to its value. I have often been struck with the heavy crops of fruit sometimes seen in cottage gardens where the bushes are growing on the brink of a brook or ditch. Where there is a choice of position, that which is low and moist and partially shaded is the best. The varieties of Black Currants are not many. Lee's Prolific being, perhaps, the best of my. Carter's Black Champion is also good, it also having the merit of not dropping so quickly after being fully ripe. Black Naples is also a good variety. Y.

Protecting Fig-trees on walls.—In

the most sheltered parts of the country the covering of the Fig-trees on walls may not be necessary, but to ensure a good crop it is essential to protect the trees in many districts. I find Bracken well packed among the branches an excellent protection. Of course it is necessary to unroll the healing or scattered branches, firing them closer home, and then cover with the Bracken. I prefer Bracken cut green and allowed to dry, covering all over with mats to keep the protecting material neat and from being blown about. If the Bracken is allowed to die down before being cut, it is brittle and worthless as a protecting agent. Figs are not readily injured when the wood is kept thin in the summer, and a good ripening season follows. It is after wet autumns that the trees suffer most, hence the necessity of protection. It is also advisable to cover with decayed manure the roots of trees requiring it. Those which are too gross should be mulched with leaves or dry litter.—G.

5253.—Pruning Vines.—Years ago two systems of pruning were advocated—the long spur and the short spur system; but all good growers now prune their Vines upon the latter

system. The *modus operandi* is this: Train a rod up from the bottom to the top of the house; but the first year it is simply cut back to 6 feet or 7 feet from its base, all side laterals to be cut clean out. When the buds start in the spring, train the top one up as a leading growth and the lower buds as lateral growths, but remove each alternate growth, as they would be too crowded. One or more bunches of Grapes will show on each lateral. At the end of the season cut back to a good eye, as near as possible to the base of the lateral.—J. D. E.

— Prune the Vines at once—the sooner the better. The rule is in spur pruning (which is the system generally adopted) to cut to a good bud. But Black Hamburg, Alicante, Muscata, and Gros Colman nearly always show plenty of bunches, and no harm will be done if they are cut back to one, or at the most two buds. There are cases where the roots have wandered away to deep, damp soil when the wood does not ripen up well, that a little longer spur may be left till time can be found to lift the roots.—E. H.

— Shorten back all the young growths of last year to within two or three eyes of their base, or in other words to the lowest strong or plump eye. Market growers of Grapes do not as a rule prune their Vines so hard as private gardeners, and obtain heavier crops and finer bunches in consequence. The reason of this is that the third eye is often much stronger than the second, and the fourth sometimes a better one still. When the spurs get ragged and "snaggy," the simplest and best plan is to cut the rod out, and train up a fresh cane from the base. Pruning should be done at once, before the sap begins to move again, especially where much heat is employed.—B. C. R.

TREES AND SHRUBS.

THE CUTTING OF EVERGREENS.

About Christmas-time and early in the new year there is usually a demand for Evergreens to use in various ways for festive decorations. It is not of their use that I now refer, but more particularly to the cutting of them. When there is a choice to a few days, a fine day should if possible be chosen. The work of cutting can then be performed with far greater comfort by the men, whilst at the same time it can also be done more carefully. It is a description of work that is oftentimes done in a perfunctory or haphazard manner, with no real thought either as to the appearance of the shrubs or their future well-being. Of course, what holds good in one kind does not always do so in another, whilst varied forms and styles of growth should also be considered. In my own case I have for several years been aiming at cutting Hollies so as to get the trees (for trees they are) into more of a pyramidal shape, not formal, as in clipped trees, but so much so as to give every opportunity for the lower branches to spread out and not be overshadowed by the branches above them. In this way I have under my care a number of well-furnished specimens from 20 feet to 30 feet and even more in height. These consist of the common Holly, the silver variegated, and the yellow-fruited kind. The soil, a light one, resting on gravel, suits them very well. Aucubas I find do best when they have plenty of room to develop into dense bushes; these when too tall are headed, 2 feet or 3 feet being taken off the tops. Young growths will follow in due course. With Laurels, a medium course of cutting is better in my opinion than either of the two extremes—viz., that of constant summer pruning to keep them, as it were, in accordance with some architect's plan, or excessive cutting down, as a workman would do it, leaving everything bare for a time. A deal may be done with Yews to keep them from extending too wide when the space is limited by merely cutting out the leading shoots. By the same process the Box-trees can be retained in a bushy and dense condition without being in any sense formal. When shrubs are taken in hand in time by judicious thinning out here and there, it will take years before they arrive at a size when a more radical course will be found necessary. This informal kind of pruning regulates the growth of the shrub and prevents strong shoots from taking the lead of the

weakening of the rest, with the consequent after results of a bareness both undesirable and unsightly also. It frequently happens that shrubs are left more to chance than anything else in the garden. As long as they look well at the time, be they ever so crowded, there is no thought given as to the future. This is a great mistake, the after effects of which cannot be so easily remedied. E.

STRAWBERRY-TREE (ARBUTUS).

The beautiful evergreen shrub (*A. Unedo*) should be in every well-planted garden, for no other is so cheerful throughout the autumn and early winter, when its dense mass of greenery is mingled with a profusion of flower-clusters and ruddy round fruit like undersized Strawberries, the result of last year's flower crop. There is no need to describe such a common shrub, which

Flowers of *Arbutus Unedo* Croomei.

is met with everywhere almost, especially in warm and coast districts, where it grows tree-like 20 feet or even 30 feet high, making huge globular masses of green. In inland districts it is liable to be cut down during very severe winters, but this so-called accident that no one need be deterred from planting it. If large bushes are killed down by cold, they almost invariably send up strong shoots again. When young it requires, in order to get it established, a slight protection during winter. It grows quickly in sheltered places, but dislikes shade, and seems to be most at home in a deep, light soil, though it is not fastidious in that respect. There are numerous varieties of this beautiful shrub, and some are superior to the original. One of the best is the red-barked Strawberry-tree (*A. Croomei*) (an illustration of which we give), which has longer and broader leaves than the common kind. The bark of the young shoots is brownish-red, and the flower-clusters larger and deeply stained with reddish-pink. The variety *rubra* has the flowers almost a bright-scarlet, produced abundantly in late autumn. One variety (*flora-plena*) has double flowers, while others differ from the original in the size and form of leaves. Thus there is the Oak-leaved (*quercifolia*), Myrtle-leaved (*myrtifolia* or *microphylla*), Willow or narrow-leaved (*salicifolia*), and the crumpled-leaved form (*crispata*), all of which are interesting, but not so beautiful as the common sort, or *Croomei* and *rubra*. The Strawberry-tree is a native of South Europe, and grows wild in the South of Ireland, and the peculiar charm it gives to Killarney is well known. The other

Species of *ARBUTUS* are not so important as flowering trees, though they are invaluable evergreens. They are more tree-like than *A. Unedo*, making large, spreading masses of bold foliage. *A. Andrachne*, with smooth, ruddy-tinted bark, is the commonest, and is hardy everywhere in the south and coast districts. It reaches, about London, a height of over 15 feet. It grows wild in the Levant, and is a very old tree in gardens. *A. hybrida*, said to be a hybrid between *A. Unedo* and *A. Andrachne*, is hardy, and in growth resembles both its parents; its flower-clusters are larger than those of *A. Unedo*, and smaller than those of *A. Andrachne*. *A. Milleri* is handsome, because its flowers are pink and its leaves large. *A. procera* (also called *A. Menziesii*), from North-West America, not a common kind, is somewhat similar to *A. Andrachne*, but less hardy, and, like it, has

large leaves and grows tall. For a coast garden it is most desirable. Other kinds of *Arbutus* named in catalogues—*photinifolia*, *magnifica*, *Rollinsoni*, *serratifolia*, *laurifolia* or *andrachnoides*—are either identical with the foregoing or varieties of them. W.

The Witch Hazels.—These form a very interesting group of winter-flowering shrubs, not of great importance perhaps, but *Hamamelis arborea* is well worth planting in gardens of fair size. *H. virginica* is the best known, but not so ornamental as *H. arborea*, the former being a wide-spreading shrub, covered throughout the winter with a mass of small yellow flowers. *H. japonica* and the allied *H. Zuccariniiana* have pale lemon-yellow flowers, and those of *H. arborea* are rich golden-yellow, and stand thickly the leafless shoots. A tree of this in full bloom on a late winter's day is beautiful, the petals twisted, and their line colour set off by crimson calyces. This is sometimes described as a shrub, but is really a tree, although not reaching more than 7 feet or 8 feet in height in England, whereas in Japan, its native country, it will grow from 15 feet to 20 feet in height. A sunny spot must be selected, and the soil should be moist and sandy. *H. arborea* is also useful to plant with other things. Small plants, for instance, in a bell, the groundwork of which is the Christmas Rose, the *Hamamelis* between the clumps, or the dwarf, leafy, red-berried *Gaultheria procumbens* makes a pleasing picture. I do not recommend the Witch Hazel to be planted before other more worthy shrubs are in the garden, but in a good garden of shrubs it may have a place for the beauty of its flowers in winter, and its Hazel-like leafage in autumn, when it takes on rich orange-yellow colouring, whilst those of *H. virginica* are tawny-yellow. As regards habit, *H. arborea* is not very ornamental, *H. virginica* being more of a bush.—F. P.

A few good-flowering shrubs.—It is a pity that in comparatively small gardens more thought is not given to flowering shrubs, and less planted of such common uninteresting things as Privet. This note is prompted by what the writer noticed recently in a garden, in which Privet was almost exclusively used. This is a mistake, and one must think that the reason is good-flowering trees and shrubs are not well known. The Barberries, Thorns, Weigelas, the beautiful Rose *Acacia*, *A. hispida* (which produces a profusion of rose-coloured flowers), The Quince, *Daphne mezereum*, Pearl Bush (*Exochorda grandiflora*), *Garrya elliptica*, the Syrian Mallow, *Hibiscus syriacus* and its varieties, *Hydrangea paniculata grandiflora* (which bears huge masses of white flowers), *Magnolia conspicua*, *Olearia Haasti*, Mock Orange (*Philadelphus*, especially the dwarf-growing *P. microphyllus*, which produces a wealth of pure white fragrant flowers, a lovely, free-growing shrub), the flowering Currant *Ribes sanguinea*, the yellow-flowering Currant *R. aureum*, hardy Spiraeas (particularly *S. arifolia* and the dwarf-growing *S. Bumalda*, or the deep-crimson variety *Anthony Waterer*, *S. Lindleyana*), Guelder Rose, not forgetting the stiffer-growing *Viburnum plicatum*, that has deep-green wrinkled leaves and abundance of white flower buds. These are the names of a few leading kinds, but then we have Lilacs and other well-known things. There is, therefore, not the slightest reason for always planting evergreens of common sorts when we have a wealth of beautiful hardy-flowering shrubs, attractive for their flowers, and, in many cases, for the rich colours of the autumn leafage.—F. P.

The Mezerium.—In mild weather the *Daphne Mezereum*, the "Mezeron" of cottage gardens, is in bloom in late winter, but is often kept back by frosts until the early spring, when the flowers send a sweet fragrance over the garden. This is a shrub for all gardens, large and small, and in the smallest garden should be planted. If it is a friend of the cottager, why not of the amateur gardener, who goes without many beautiful things apparently because they are unknown to him? The Mezeron will grow almost anywhere, and requires a sunny spot. I know of an old bush that has flowered splendidly for many years past in a small front garden by a dusty roadside. The flowers are

purple, deliciously fragrant, and stand thickly the leafless shoots. There are, however, several varieties, the flowers varying in colour from pink to white, and also an autumn-blooming variety, named *autumnalis*, which has deep purple flowers. Besides the type, however, a favourite of mine is the double white and the single white, which are all as if covered with snow when in full bloom. They flower just a little later than the type, and in large gardens are worth planting a good deal, either in a group or to fill a distinct bed.—C. T.

5254.—**Cutting back a Magnolia.**—If there is no more room for the branches of the Magnolia to extend they may be cut back, but do not do so until all danger of very cold wind is past. The end of April is quite soon enough to prune it. I do not like cutting away any of the front shoots, as there is danger of removing some that would flower. The main-stem should be secured to the wall with strong mals and tied with tar cord; to these the smaller branches may be tied so as to cover the whole of the space with foliage. Never mind about the shoots crossing each other, or their being four or five thick, because if any of them close to the wall die they can be cut out. The object should be to keep the plant well clothed with foliage, and then plenty of flowers generally follow. You cannot strike this Magnolia from cuttings; it is increased by layers. Even this, however, is a slow process, as it takes two years for the layer to make sufficient roots to bear being moved. Layering is done by bringing the branch down on the ground, burying a part of it 3 inches below the surface, and fixing it there with a strong peg. Make a small mound of earth over the part buried, and fix a stick to the end of the branch, so as to bring it up in an erect position, there is then nothing more to be done but to wait.—J. C. C.

The Magnolia may be cut back, but not now; wait till spring. If the plant is healthy it will break out of the old wood. May be rooted from cuttings under glass in sandy soil, kept close, though layering is a better plan.—E. H.

5255.—**Poplars.**—You may safely reduce the height of your Poplar trees to anything you like. It will not, however, materially decrease the root action, as they will soon begin to grow again. Seeing that they are pressing against the garden fence, and that you do not want such high trees, you had better take off their tops at once, and from these take some of the young straight branches and plant them between the existing trees. The branches may be 4 feet long, which should be planted in a trench dug out 1 foot wide and the same in depth. If you press the soil firmly about them they will form roots, and before the end of the summer will make some top growth, and in a few years develop into trees. You can then remove the old trees altogether. You will, of course, plant the young ones farther from the fence than the existing trees.—J. C. C.

—These trees will bear cutting back to any reasonable extent without injury, though it spoils the appearance of the Lombardy variety, of course.—H. C. H.

—Lopping Poplars will not injure them, and it will decrease rather than increase the root action—for some time, at any rate. Lopping will reduce the wind power, and they will consequently not press so much against the garden fence. The Poplars are probably the Lombard species.—E. H.

5244.—**Showy Hibiscus.**—All the varieties of the hardy *Althea frutex* or *Hibiscus sylvaticus* are good, except those with striped or bright coloured flowers. Avoid the horrible purple one seen in gardens, and select such as *Celeste* (blue), *carneo-plenus*, *albus plenus* (double white), and *Leopoldi*. This is a fine shrub, far too neglected in gardens, although quite a treasure, blooming late in the summer when very few shrubs are in flower. It depends upon the soil to what height the tree grows, in moist, deep ground, growing many feet high. I have seen several examples in Battersea-park, thus showing that it is a good tree or shrub for town gardens. Remember that it requires a good foundation, so to say, this being a deep soil, otherwise the results will be far from satisfactory. It is a good shrub to make a group in on the outskirts of the lawn, or to plant in front of shrubs with deeply coloured leaves, these bringing into bold relief the large, handsome flowers.—C. T.

Jasminum nudiflorum.—This is common enough in gardens of all sizes, but it is never grown in a really good way. It is left too much to itself, but when well grown few shrubs

are more beautiful, the shoots covering walls or fences and laden with bright yellow flowers in late autumn and throughout the winter even when the weather is mild. Such a climber is worth far more than ordinary treatment and certainly gains in beauty when the shoots of Ivy are trained amongst those of the Jasmine, the deep green and yellow mingling in a pleasing way. The Jasmine will grow in ordinary soil and the most exposed positions, but is always freer in bloom and growth when the more sheltered spots are chosen, as the flowers do not get cut about by inclement weather.—C. T.

Chimonanthus fragrans grandiflorus.—The sweet-scented *Chimonanthus* is a very old friend. It was introduced here as long ago as 1770 from Japan, and the variety *grandiflorus* is the best to grow, the flowers being much larger than those of the type. They appear without the leaves on the twigs, and are rather inconspicuous, as the white-yellow colour is very pale, but atoned for by the delicious perfume. It is unquestionably one of the, if not the, most fragrant shrubs in gardens, and a few sprays cut for the house are a welcome addition to the winter posy. The soil in which this shrub is planted—for a shrub it is, rather than a climber—should be rich and deep. Keep the growth nailed carefully to the wall, and, after the flowering period cut back each year those shoots that have bloomed, except the chief ones, which require little shortening. The new growth will bloom freely the following year. I sometimes see questions in *GARDENING* about the propagation of the *Chimonanthus*, which is best done by layering in the autumn months. There are several good specimens in England, one at Syon House, Isleworth, which covers a large space on an old high wall, and gives plenty of the flower-laden shoots to fill the winter bowl.—C. T.

TREE OF HEAVEN (AILANTUS).

This is a well-known hardy tree, young plants of which cut down every year give a fine effect in the flower garden, and can be depended upon to do this in all seasons. The *Ailantus* should be kept in a young state, with a single stem clothed with its superb pinnate leaves; it can readily be kept in this form by cutting down annually, taking care to prevent it from break-

Tree of Heaven (Ailantus).

ing into an irregular head. Vigorous young plants and suckers in good soil will produce handsome arching, elegantly divided leaves 5 feet to 6 feet long, not surpassed by those of any stove-plant. Propagated easily by cuttings of the roots. It is a native of China and Japan.

5224.—**Ailantus glandulosa.**—I have one of the above trees, but I never prune it. Its common name is Tree of Heaven, called so by the Chinese. The other tree, *Dimorphanthus mandchuricus*, is a tall growing tree with leaves measuring a yard across, closely resembling the *Samach*, the stem being covered with thorns, also the ribs of the leaves. The flowers are borne on the top of stem, seeds size and black like *Elaeagnus* when ripe. It is a rare thing to ripen seeds in our country. Last summer, being very hot, it did so with me. Both natives of Japan.—E. VORLES, *King's Norton*.

RULES FOR CORRESPONDENTS.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.*

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as our knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number to which they appeared.

5203.—**Tomatoes under glass.**—At what distance should Tomatoes be grown from the glass?—J. F. P.

5204.—**Oil-stove.**—Would it be injurious to plants to put an oil-stove in a conservatory to heat it?—A. B. C.

5205.—**Pancreum fragrans.**—Will someone kindly let me know how to treat *Pancreum fragrans* after flowering?—QUESTAST.

5206.—**Colous-cuttings.**—When is the right time to strike *Colous*-cuttings, what compost is most suitable, and how should they be done?—J. F. P.

5207.—**Vegetables for show.**—Will someone please to inform me the time it takes to grow Beet, Carrot, Parsnip, to perfection for show?—T. W.

5208.—**Gloxinia bulbs.**—Ought *Gloxinia* bulbs to be allowed to get rot in the winter? And if not, what is the cause, consequence, and cure?—A. E. W.

5209.—**Privet from cuttings.**—Would someone kindly inform me the best time to put in cuttings of Privet, as I have a young hedge I am about to cut down?—I. P. R.

5210.—**Tomatoes, &c., in a greenhouse.**—In a greenhouse (span-root) 2 fruit by 6 feet, would it be possible to grow Tomatoes and Cucumbers? If so, how many of each?—J. F. P.

5211.—**Cider refuse.**—Is Cider-mess (the refuse from filter-making) when thoroughly rotted and refined to (black) soil, a good substitute for leaf-mould? It is extremely light.—J. F. P.

5212.—**Ipomoea pandurata, &c.**—Will anyone kindly give me some information as to the treatment of *Ipomoea pandurata* and *Cliffort's Hardy Ipomoea*? I cannot get them to blossom or even flourish. They just live.—A. B.

5213.—**Cinerarias.**—The leaves of many of my *Cinerarias* curled up this autumn. They were kept in a cool-house, with moderate watering, dusted with sulphur, without much effect. What was the cause and cure?—A. E. W.

5214.—**"Geranium"-cuttings.**—My "Geraniums" in a greenhouse are making quick growth. Would this suit your growth if inserted now in a temperature of 55 degs, as cuttings make good plants for summer bedding, and would the old roots make new growth and blossom in summer?—J. F. P.

5215.—**Treatment of Ferns.**—How ought Ferns to be treated when a reptile? I do it as follows: I cut off all the leaves, many of which are dead, and have the roots, which have usually formed a hard mass, and filled the pots. I then shake away the rest of the mould, repot in a sandy mixture of loam and leaf-mould, and give a copious watering. Is this right?—A. R. W.

5216.—**Making a propagator.**—As the time will soon arrive when the use of a propagator will be required by amateurs to raise such things as Tomatoes, cuttings, &c., it would be a real benefit if someone would kindly advise how to construct a simple contrivance to be heated by a small lamp, and state what kind of oil or spirit should be used to avoid the collection of carbon above the flame?—W. G. T.

5217.—**Osmanthus.**—In my garden in Hampshire I have four plants of *Osmanthus*. They never have blossomed until this year. One of the shrubs was moved and planted to the north. It was a mass of bloom in September; the scent of the flowers so strong they scented the whole space in front of the house, and so continued until the frost came. Would not the *Osmanthus* force well?—F. H. C., *Wokingham*.

5218.—**Wireworms in leaf-mould.**—Will "J. C. C." kindly help me again out of difficulty? Last autumn (twelvemonth) I had the falling leaves mule into a heap, which has been a good deal turned up, but it is full of wireworms. What can I do to get rid of them? It is well spread out on the empty spaces in the vegetable garden now would the frost kill them? I wished to use it for a Potato-bed.—IVY BANK.

5219.—**Starting Begonias.**—I have some *Begonia* tubers I want to bloom outside next summer. I have cold-frames, but no greenhouse. Will someone kindly tell me when and how best to start them? Would they do planted in a box about the end of February or the beginning of March, and placed on a warm shelf in the dwelling-house, and when struck potted singly or transplanted into a cold-frame until bedded out?—AN AMATEUR.

5220.—**Fruit-trees trained on a wall.**—Mine have been trained for years by nailing with shreds to a brick wall. I think the shreds and holes, made by a succession of birds in the wall, harbor insects. Is this so?

And would it be better to train the trees by tying them to wires strained along the wall after "pointing up" and stopping the existing holes? If so, how far apart should the wires be? The trees are Peaches, Apricots, and Green Gages.—H. G.

6281.—Growth on pots.—I have been troubled lately by a white growth on some of the pots in my greenhouse like the white mould on a damp cheese. Temperature of the greenhouse averages about 50 degs. It does not appear to come from overwatering, as some of the plants have been allowed to get quite dry, and yet have it. I use Ichthonic Guano liberally at times. Can it come from this; and if so, is there any prevention? Or is it that there is not enough sand in the soil?—A. B. W.

6282.—Shrubs in a garden.—I have an old house, which is surrounded with grounds planted with Rhododendrons (fancy and common), Yews, Hollies, Portugal and common Laurels, and Box, all of which have grown up into a neglected mass—the Rhododendrons being 6 feet to 8 feet high; the Yews spread out into great awkward bushes; the Hollies with a dozen bushes; and the Portugal and other Laurels are 19 feet to 12 feet high, and with great branches as big as one's arm—in fact, all tangled together and spoiling one another. I am told my only plan is to cut them all down to about 2 feet from the ground in the spring, and that they will then shoot into round bushes, and I shall in the autumn be able to move them. Will someone kindly tell me: 1, Is this correct? 2, What is the best time to do this? 3, Will they be very much injured in the autumn of the same year that they are cut?—Y. A.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

6283.—Coclogyne Dayana grandis.—Pondicola for the proper treatment of this plant? Mr. Curtis found this species in Borneo growing upon branches of trees near the streams in the hot lowlands. I should say it neither requires cool treatment nor drainage.—M. B.

6284.—Cypripedium montanum vars.—Faulstich asks for details of the management of these Orchids? They will grow equally well under roof or full treatment with the other forms of this species. I prefer the former, however, for B, using a little loam in the soil.—M. B.

6285.—Odontoglossum Nebulosum.—J. H. and F. T. both send me flowers of this species, which appears to be a somewhat singular time for them to be blooming. They are, however, good, small flowers, and speak well of the atmosphere about London this season; but if we had a continuance of the fog of last Saturday night, they would have stood a chance of being cut off, I am thinking.—M. B.

6286.—Dendrobium Euclophotum (H. Myers).—This is the name of the plant, and a very long time it remains in flower. I believe it was imported some few years ago from the Malay Archipelago by the Messrs. Veitch and Sons. It has a somewhat fanciful name, but it has recently several varieties of semi-white flowers, which appear to be at a time when very few Dendrobiums are flowering.—M. B.

6287.—Epidendrum ambiguum (J. Beiler).—Yes, this is a very novel-flowered plant, and yours is a very good form of the old species, with the lip of a nice straw colour, and which I like far better than the form having a white lip; both, however, have the blooms excessively sweet. It thrives best when grown in a libok of wood, with a little Sphagnum Moss, and hung up at the warm end of a stove-house.—M. B.

6288.—Dendrobium densiflorum and D. crassinode (T. J.).—These are plants which both require to be kept cool and dry; the first named is, however, an evergreen plant, and does not require so great a drying as the last named, which is a deciduous plant, and which should now be about sending up their flowers, and in which case they require more water and greater heat, and more water as they are beginning to grow again, whilst D. densiflorum must be kept dry and cool for some months later yet.—M. B.

6289.—Oxleya Triana is a fine flower which came to me on Christmas Eve, so that I may say, with a great deal of truth, that I have never been without a flower of some of the hibiscus section for more than a week at a time for the whole season. The photograph sent by Mrs. Burton appears to be of a very good variety called delicate, which is very beautiful, and is preferred by many to the absolutely pure-white form called alba; but this does not hold good whenever it comes in a matter of size or purchase for then the pure-white flower has the ascendancy.—M. B.

6290.—Odontoglossum Uro-Skinneri (J. Jenkins).—Yes; I know a good many British growers who have a great aversion to such freaks; but it will be not of the least consequence after the plant has done blooming. The right way for this plant to adopt is for the spike to rise up from the side of the bulb near the base, but at other times they do proceed from the apex of the bulb, but it is not so frequent as when it occurs to Vanilla, Saccolabium, upon which I have seen it occur, when the growth is stopped, and that stem grows no more, but some side shoots.—M. B.

"Gardening Illustrated" Monthly Parts.—Price 5d., post free, 6d. The Garden Monthly Parts.—This journal is published in monthly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 8d. Complete sets of volumes by THE GARDEN from its commencement to the end of 1892, forty-two vols., price, cloth, £30 12s. Farm and Home Monthly Parts.—This journal is published in monthly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d., post free, 6d. Hardy Flowers.—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. With many Popular Hints. 1s.; post free, 1s. 3d. London: 17, Southwark Street, Strand, W.C.

ROSES. ROSES.

THE BEST and CHEAPEST in the WORLD. 12 acres of Roses. 100,000 grand plants to select from. Forty choice Perpetuals for 21s. Purchaser's selection from 400 best varieties. Catalogues free, 18 Choice Standards or Half-Standards for 21s. Purchaser's selection. The following are my selection, carriage free, cash with order: 20 choice dwarf Teas and Nisettes, 12s. 6d.; 12 choice Climbing, 7s.; 12 best Hybrid Perpetuals, dwarf, 7s.; 12 beautiful Teas and Nisettes, 3s.; 6 Intro yellow Roses, 5s.; 6 Maréchal Niel, 5s.; 6 Glorie de Dijon, 4s. 6d.; 6 choice Moss Roses, 4s.; 6 Gold Cabaret Roses, 4s.; 6 old-fashioned Roses, 4s.; 6 crimson Monthly Roses, 3s. 6d.; 6 pink Monthly Roses, 2s. 6d.; 6 white Monthly Roses, 3s. 6d.; 6 quick-growing Climbing Roses, 2s. 6d.; 12 Sweet Briars, 3s. My selection, cash with order. Thousands of Traditionals, Catalogue free. JAMES WALTERS, Rose Grower, Exeter.

GEORGE BOYES & CO.,

30,000 CHRYSANTHEMUMS.—300 splendid varieties, the very cream of the best: Mrs. J. Wright, Mrs. F. Clinton, Lady Selborne, Bouquet des Dames, Albert-Lambert, John Lambert, Mons. W. Holmes, Voltaire, Yellow Sultan, Snowdew, Earl Alesander Purian. This set alone, well-rooted plants, 1s. 6d. 6,000 PEARLARGONIUMS.—12 good varieties, strong, well-rooted plants from 3-in. pots, named, 4s. 15,000 BEGONIAS.—One-year tubers, splendid strain, blooms 4 inches in diameter, 3s. per doz. 5,000 SPOTTED CALCOLARIAS.—Best strain in cultivation, strong plants, 2s. 6d. per doz. 30,000 GERANIUMS.—12 grand varieties, all colours, true to name, 3s. All free by post for cash with order only. AYLESTONE PARK, LEICESTER.

NEW CHRYSANTHEMUMS.

GOOD AND DISTINCT NOVELTIES. MISS SYLVIA SHERA. The best English Seedling of the year. 7s. 6d. each. SOUVENIR DE MME. DULLIER. The Premier duck variety. Unusually superior to W. Seward and H. W. Child. 6s. each. LE M. L. DE JEFFY. High yellow, edged crimson. A superb variety 5s. each. EDA FRASER. Delicate Peach blossom in colour. Large and handsome bloom. 3s.; cutting, 1s. 6d. MILDEN WEDDING.—Best of all yellows, 1s. 6d.; cutting, 1s. Beauty of Kentucky, Mrs. Galen, Louise, and all other vars. in strong, healthy, country-grown cuttings or plants. See Catalogue free.

TREES AND SHRUBS.

FOREST-TREES NEAR GARDENS.

The kitchen and fruit gardens should be kept quite distinct, and apart from the ornamental portions of the ground, for the former cannot possibly produce fine fruit or vegetables if overshadowed by lofty trees, while the latter can hardly be ornamental without them, and any attempt to effect a compromise usually ends in failure. Forest-trees are frequently used for sheltering the fruit and kitchen gardens from cold winds, but it requires a correct knowledge of the distance the roots of any given kind will travel, or a good deal more than goal may be done by the shelter, for Ash, Elm, and many of the deciduous trees one finds planted close up to the kitchen garden will send their roots quite as far from the base of the tree as they will send their branches up in the air, and a full-grown specimen will attain from 80 feet to 100 feet in height, and it is really waste to labour and manure to attempt to cultivate crops in their vicinity, for although they make a feeble attempt to grow, the strongest-rooted subject soon gets the mastery, and nothing short of grubbing up the trees will remedy the evil. Evergreen Conifers do not send out their roots to such a distance as deciduous trees do, and in addition they give shelter more at the time it is really needed, for it is in the early spring that bitter winds are so trying to vegetation, and a plantation of Scotch or Spanish Firs gives quite an improved atmosphere to a garden; but they must be at least 50 feet from the boundary, as I would rather grow my fruit and vegetables in an open field than in a garden that was shaded as well as sheltered by lofty trees.

J. Groom, Gosport.

A good variegated Dogwood.

Variegated shrubs, as a rule, are not worth much, the variegation being sickly and producing bad effect in the garden. But an exception to the rule is the Variegated Dogwood (*Cornus sibirica spathi*), which is not only well variegated, but the leaves are not influenced by a hot summer sun, as are many things, whilst it dies off in the autumn of a rich scarlet shade. The leaves are of a golden tint in summer, and the shrub is perfectly hardy, growing in ordinary soil and a well-exposed position.—C. T.

Hydrangea paniculata.—There are few more beautiful dwarf shrubs than the variety of *H. paniculata* known as *grandiflora*, but much disappointment is sometimes caused by purchasers not getting the true form. They buy the species, which is far less beautiful than the variety, so in purchasing be careful always to name the variety. The flowers of *H. paniculata grandiflora* are borne in profusion in large, massive heads, and when the shrub is grouped on the outskirts of the lawn it forms a splendid feature at the flowering time.—C. T.

5282.—**Shrubs in a garden.**—Such a tangled mass of shrubs certainly requires cutting; but I should not cut all down to 2 feet.

For instance, the Yews, Hollies, and Rhododendrons may be cut into the shape you want them to assume; the Hollies, for instance, may have the number of leaders reduced, but unless naked at the bottom they may not require cutting down. Yew trees, again, may be cut to form pyramids, as they will break very well from any part of the old wood. Rhododendrons may be treated on the same lines, as may also some of the Portugal Laurels. Common Laurels and other common things may be cut down lower to form undergrowth. A judicious pruner, instead of cutting all down to one level, would aim at producing a picturesque group, retaining as much individuality as possible. In the autumn, after cutting down, some may be moved if necessary. Cut them back in March.—E. H.

On the whole you have been rightly advised about the shrubs. You will, however, find that the better forms of Rhododendrons and great Box-trees do not respond so readily to being cut down as the others. There is no help for this, and therefore they should all be dealt with alike; but do not be persuaded to cut down some branches and leave some; leave the whole of them or none at all, as it frequently happens when some branches are cut down and others left that those which remain use up all the strength of the roots, and as a consequence the cut-back parts die. If I hesitated at all about leaving any of the shrubs untouched or only lightly pruned in, it would be about the choice Rhododendrons. If these are not too much in growth, I might be disposed to prune them into shape, if it can be done without cutting into wood not more than two years old. If the garden is much exposed, wait until the end of March before doing the work. In a sheltered place the cutting down may be done three weeks earlier. I do not think any of them will be ready to move in the following autumn; certainly not the Box and Hollies. The latter should not be moved at all.—J. C. C.

The best plan will be to cut all the plants hard back in the spring as suggested. April will be the best month, as then they will break into fresh growth directly. I should not cut them all down to the same height, but leave some 3 feet or 4 feet high—the larger plants towards the back, I mean. Early next November go over the borders, digging out any that have not broken well, or are not wanted, and disposing the rest to the best advantage. If the plants are cut round with a sharp spade about a month beforehand, they will move both better and more easily, and by dropping in a nice young plant here and there towards the front, a very good effect may be made. In case any of the shrubs break very thickly, the shoots had better be carefully thinned out—that is, unless you prefer "pin-cushion" plants to natural ones.—B. C. R.

5277.—**Osmanthus.**—The *Osmanthus* appears to have blossomed in many gardens last summer where it had never done so before. The explanation lies in the exceptional weather we had last year. Given suitable treatment, the *Osmanthus* might be available for forcing; but it would, however, require to be grown in pots under glass for a great part of the year.

rip up the wood, without which it is very evident it would not always form flower-buds. It is, no doubt, a very suitable plant for a cold house if it was always kept under glass, as the foliage is always presentable.—I. C. C.

6590.—**Privet from cutting.**—Privet cuttings may be planted at any time now in open weather. It is one of the easiest plants to strike from cuttings, if planted 3 inches or 4 inches deep, and the soil made firm.—E. H.

Privet strikes very freely from cuttings, and it may not be too late to put them in now. It is usual to get good, well-ripened young growths taken off at a joint, and put them in somewhere in the open garden early in November. They seldom fail to do well. It is necessary, or at least best, to cut through the young shoots at a joint, and in planting treat them in firmly.—J. B. E.

The early autumn—in October or November—is the best time to insert the cuttings, but it may be done now, or as soon as the weather permits, and if placed in a border that is lightly shaded from the sun, and kept moist to dry weather in the spring, most of them will root yet.—H. C. H.

The best time is autumn; but you can put them in about the middle of February with fair prospects of success. Make the cuttings about 9 inches or 12 inches long, and plant them in sandy soil three-fourths of their length. Make them firm, and use the hoe among them a few times in the spring.—F. H.

Verbenas.—Whilst very little interest can be found in Verbenas grown in pots and kept under glass, or planted out in frames where they may produce fine trusses of flower to be loaned for exhibition, there is much that is interesting and beautiful in plants grown in the garden, wherever or anyhow in the summer. Whilst named varieties are still grown in some gardens, and last year I met with a stock of Purple King, Scarlet Defiance, and other old ones at Abinger, Surrey, yet the bulk of plants seen in gardens now is raised from seed, which has so far become asserted that plants can be furnished from seed, white, blue, scarlet, and flaked coming fairly true to colour. That form of raising plants is so simple because no trouble is given to put in cuttings in the autumn or to keep them safely through the winter. It is rather a surprise to find that with so strong a taste prevailing for mixed flower-beds in the summer, especially of the kind that has a carpet of creeping plants and tall plants thinly disposed, seedling Verbenas are not largely employed for carpeting purposes. White, blue, and scarlet hues blend very well, and would make capital groundwork for *Fuchsias*, *Cannas*, *India-rubbers*, or similar plants. Seed may be sown in warmth during February or early in March, and will with ordinary care give strong, well-hardened plants in 3-inch pots to plant out towards the end of May. It is an advantage that, once well seasoned, Verbenas are fairly hardy, much more so indeed than are many other summer bedding-plants. We cannot use Begonias, now so much the rage, for filling beds everywhere, and Verbenas have a grace and elegance about them that even Begonias lack.—D.

5261.—**Growth on pots.**—The white mould you mention certainly does not come from overwatering. The cause lies in the opposite direction. Your allowing the plants to get dry simply increases it. Soft, or insufficiently burnt, pots turn green when wet, and white when dry. It is a certain sign of the state the soil is in. If you keep the plants in the white mould will swell slightly, and soon become a green, mossy fungus. Drought is the sole reason for it.

GARDEN WORK.

Conservatory.

Keep the fires very steady in frosty weather. It is a great advantage to have plenty of piping in the house. When it is necessary to make the pipes very hot in order to keep out frost, the hot, dry air will injure the plants near the pipes. I have tried a good many others, but know nothing better than the improved check-out saddle, which is large enough for its work, and properly set; but all boilers are wasteful which require to be worked with the damper out and bottom doors wide open. It is very important that the fires be kept close a week or at least the fine brick and small line should be used. The fires also should be large enough, the capacity being not less than 4 inches wide for large boilers, and the taller the chimney the better. The best fuel is a mixture of gas coke and Welsh coal, using the latter freely when making up the fire for the night. Look after the late Chrysanthemum cuttings. Plants which are slow in starting should be placed in heat. It is a good plan to grow a plant of each sort under a more natural system than is usually adopted for producing cuttings. The highly-fed plants sometimes fail to produce sufficient cuttings, or else they come late. Young plants as soon as rooted should be lifted from the propagating frame and taken to a cool light house to ensure a sturdy habit. Weak plants always remain to a certain extent in a backward condition. *Thyrsanota*, *Primas*, and *Cherarias* are making showy groups now. Keep the *Chirrarrias* in the coolest part of the house, and keep close after the greenery. In warm-houses *Chirras* will be fine unless *Tokeaco* fumes are occasionally used. The worst of smoking in houses of mixed flowering plants, the blossoms of some will be sure to suffer if the fumes of *Tokeaco* are strong. *Loelia graebiana* are still beautiful, and the rarely flowering *Aranias* are getting showy. *A. Drummondii* makes a neat-haired plant for this season. When any plants go out of flower is the best time to do what pruning is required, and then the new growth comes away where required. *Paeonias* when well grown and healthy are best at this season. They stand a winter in a house better than *Hydras*, otherwise they require similar treatment—should be cut back after blooming, and placed in a rimy air work to start their new growth. There should be plenty of White *Azaleas* in bloom now, and specimen plants elevated on ornate pots are very attractive objects. *Arum* families are plentiful now. Liquid manure will help them.

Unheated Greenhouse.

The *Chrysanthemum* will suffer from severe frost, but if the house is covered the late flowers will keep tolerably fresh. *Chelera arborica* makes a good-sized evergreen bush, and produces freely in winter its beautiful white flowers, resembling the flower of the Lily of the Valley. It will do very well without fire-heat. I saw a large bush in flower the other day in a cold-house, and wondered why it was not more common. Pots of hills must be covered in frosty weather. Covers made of paper will do. With care in the matter of covering, a good many things may be grown without fire-heat. Cuttings of *Chrysanthemum* should be inserted in small pots of light sandy soil, and be plunged in Cocoa-nut-fibre in a small frame in the house. The frame can be covered to keep out frost. Keep *Auriculas* free from mud and decaying leaves. A top-dressing may be given shortly, and dry pot-bound plants may have a small shift. Scarcely any cuttings or new ones will be completed, but for peeling *Auriculas* that was formerly thought necessary. Good sound loam two-thirds, and one-third old cow manure and leaf-mould with some sand will make a good compost either for peeling or top-dressing.

Stove.

Let the temperature in frosty weather drop in sympathy with the condition outside; the plants do all the better. Very hot stoves are always more or less injured by rising the atmosphere too much, and there is also the further risk of the boiler or pipes giving way. A split socket near the boiler on a frosty night is a troublesome matter to deal with. As a temporary remedy I have generally called in a blacksmith and got a shackle made to fit the socket, and fitted a pad or portion of red lead, putting over the leaky socket, and screwed the shackle down over the leak. This will stop the leak, and when the weather breaks the family socket can be cut out. Soil may be got in somewhat of a readiness for peeling, including some good *Theraps* (as *Chimbas* planted in beds and borders will require some removal of the soil next month. *Calaminas* which have had a good rest may be divided and repotted, also *Adimemas* and *Gloxinias*.

Fig-houses.

Where Figs are forced the trees should be now in a condition for starting. A light temperature 50 degs., to be increased to 45 degs. and 40 degs. as the plants break into growth. When grown in pots if there is a hot-bed in the house the pots may be plunged. A little bottom-heat helps the plants, though it is not absolutely necessary; at least, good Figs are grown without bottom-heat. The perfect ripening of the wood has more to do with success than hot-bottom-heat. Use the syringe daily in fine weather, and stop the young shoots when the leaves have been made.

Pines.

Get a lot of good turfy loam under cover for potting and top-dressing next March when the weather is settled. Plants with the fruits recently started may have warm liquid-manure whenever water is required, which will not be oftener than once a week at present. A light drawing out with the syringe on bright days will be beneficial to all plants, except those approaching the ripening stage or those in flower. Suckers may be taken from old stools any time when there is a brisk heat to start them in.

Window Gardening.

There is not much movement yet, and the season is young for repotting or propagating. The chief work is to keep plants clean and healthy, and safe from frost. As

soon as *Fuchsias* show signs of growth prune back to put into shape and repot, shaking away as much of the old soil as will permit of the plants going into the same sized pots again.

Outdoor Garden.

Snow is Nature's own covering, and in a general way it is not advisable to remove it, but when it hangs heavily on evergreen trees, such as *Cedar* of Lebanon and other Conifers, it should be taken off to prevent its weight splintering the branches, and spoiling the appearance of the trees. The *Cedar* of Lebanon, the *Atlantic Cedar*, the *Spanish Silver Fir*, and *Normann's Silver Fir* are the most reliable of the Coniferous lawn plantings, and they usually do well on clay soil, where the drainage is free. The *Cedar* of Lebanon grows slowly at first, but when well established the growth is rapid. Some years ago I measured some specimens of the *Lebanon Cedar* growing in heavy clay soil in Huntingdonshire that had been planted sixty years, and the average height 4 feet from the ground was 10 feet. There are not many handsome trees than the *Lawson Cypress*. When raised from seeds there is a great variety among the plants, the most distinct of which have been named, and a group of a dozen varieties will give character to any place. They transplant badly, unless frequently transplanted. Now that the majority of the trees in the shrubbery are leafless the *Lawson Cypress* stands out boldly, and gives an idea of warmth and shelter that everybody can appreciate. As soon as the snow goes the work of planting, digging, &c., can go on again, but borders containing hills should be set well-drained till the hills are through, though a top-dressing of manure will be beneficial. All *Thorns* and other hedges may be cut back now. Holly hedges should be cleaned out top-dressed.

Fruit Garden.

Place more *Strawberries* in gentle heat to start them. Sow seeds of *Melon* for early work. It will be a great advantage if the pot-Vine house can be covered with *Frigidum*, fixed on rollers to work up and down. It not only economizes the fuel, but it keeps the atmosphere of the house more equal. When the wind is strong a few of the house may be covered for a few days to force the hills to break with greater freedom and regularly, only, of course, this could not be done where other plants are grown with the *Vines*. The second riny may soon be started; everything therein should now be clean and sweet, and the border in a moist, healthy condition. When well made, it is a partial to inside borders. They are more under control than borders outside, and are more suitable for early and late crops. Sixty-five degrees at night will be high enough for *Black Maulduras* and *Sweetwater*. When in blossom *Foster's Seedling* is a good forcing time, but is not large enough for later crops. I think more might be done with the *Golden Queen*. Its appearance when well grown is it is nearly equal to the *Muscot*, and will carry a heavy load without injury. The thinning of the branches where too rounded in orchard trees may be done during frosty weather, if this frost is not too severe. I do not suppose anyone would care to do such work now. The *Thorn* and *Wine* are now in the warm air, and such work may be done, and where the trees are mossy some efforts should be made to clear it off. Strong linewash from fresh hot lime is as good as anything.

Vegetable Garden.

Frames being used for forcing vegetables must have plenty of covering to keep up the temperature. A line of faggots or straw-sticks round the frames ground, if exposed to cold winds, will tend to keep the warmth steady. Of course, a good Holly hedge will be better, but Holly or Yew hedges cannot be improved, and the shelter of *Prasika* may. Sow *Vans* and *Beans* under glass in pots or otherwise, but transplanting when the weather is suitable. Everybody has their favourite early *Pras*, but *American Wonder* or *Chelera Gem* are good for the small garden for the earliest crops, and the rows need not be further apart than 18 inches. I always think even these *Pras* pay for a few sticks to keep them off the ground. Winter *Broccoli*, with heads just beginning to form, sown in frosty weather, and all such plants should have been filled and placed in a safe place before frost sets in. With plenty of covering they are quite safe laid in a trench, with the stems buried up to the leaves. In frosty weather clear up rubbish-heaps, turn over compost-heaps, wheel manure on vacant land. See that no harbour is left anywhere for snags, snails, or other insects. Where there are heaps of rubbish lying about, mice, rats, and other vermin soon congregate. The best way to get rid of them is to get a little red-hot iron, and will pay for it, as many things besides *Musdrovians* can be forced there; *5 degs.* to *6 degs.* is a general temperature. Snipe the floors should be atmosphere be dry.

E. HOSIAR.

Work in the Town Garden.

As soon as the days begin to gain a little in length most gardeners begin to think about shifting on a few of the best of the autumn-stuck plants, such as *Zonal* and other *Pelargoniums*, *Fuchsias*, *Helioliums*, *Marguerites*, and *Petunias* for early flowering. This with a smoky atmosphere to deal with it is not a good idea. It is better to begin now with the plants which will result in a little better than a hot, and will pay for it, as many things besides *Musdrovians* can be forced there; *5 degs.* to *6 degs.* is a general temperature. Snipe the floors should be atmosphere be dry.

Gloxinias, *Achimenes*, and *Tylosas* may be started for early flowering, but it is almost too soon for *Begonias* (tuberous) yet—at least, in Iowa I have had *Gloxinias* started beautifully in bloom in April on a high shelf near the glass in a warm-house, where there was a lot of both sun and fog to control with; but the *Begonias* require more light and air also, and under the circumstances are better if allowed to remain dormant until February or the beginning of March. The new hybrid *Streptocarpus*, though the numerous plants, like *Stylosis* of *Stylosis*, are of a lovely different nature, they do not form true tubers, nor yet the down entirely. At any time, but remain more or less green through the winter, and start into fresh growth in the spring. I purposely left a few in a house, to which the frost gained an entrance, to see what effect it has upon them. Several of these charming plants, as also of the *Tuberous Begonias* and *Gloxinias*, may be sown at any time now in a warm-house or pit, and if grown out freely the plants will flourish this season.

B. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from January 20th to January 27th.

Turned over and prepared a bed of *Humulus*. A layer of cow-manure has been placed in the bottom of the bed. Without this layer of moist manure it would be difficult in our dry district to keep such moisture-loving plants in good condition. I have sown a few *Auriculas* and top-dressed *Auriculas* in frames. I never use anything but turf-loam and two-year-old cow-manure for this purpose; two-thirds loam to one-third manure suits them well. Looked over *Auriculas* in pits to pick out dead leaves, and stir up surface soil. Cut down a lot of *Zonal Pelargoniums*, which have been in flower up to the present, and put in the cuttings. I wait more stock. They have not been cut very hard back, so the plants being in heat will soon break, and come into blossom again in March. Looked over stock of *Helioliums* and other things, of which cuttings will be required next month, and moved some into a warm room to induce growth. Sowed seeds of *Castorolis*, *Wigandias*, and other sub-tropical plants, as large plants are wanted for turning out early in June. The variegated *Tree Mallow* (*Malva arborea variegata*) has also been sown, as to be useful early in summer the seeds must be sown early. The young plants come green at first, but the larger leaves soon beautifully mottled with creamy-white. This makes a striking plant for the conservatory when grown in pots, and particularly of a shabby rhazodis. Thinned *Grapes* in pot-vinery, chiefly *Humburg* and *Foster's Seedling*. Sowed *Holly* *Beans* to form a succession to those running into bloom. Watered *Musdrovians* with liquid-manure, and made up another bed in the place of our just removed. A little fire-heat is used now to keep the temperature between 55 degs. to 60 degs. *Sakale*, *Rubra*, and *Thorny* come on well in this temperature. Looked over *Auriculas* to fasten the soil round the plants after frost, but as the hard binder soils were put out early in October they were well established, and the lifting power of the frost has had little effect. Still, a look round is always desirable after frost. Sowed and trained *Chimbas* *Jackman* on wire arches. *Honey-suckles* also were attended to in like manner. Cut back a *Thorn* outside kitchen, which has got rather thin in the loam with age. Shant plant a few *Privet* along the bottom to fill up, and this will give an evergreen character to the fence, which will improve its appearance. Planted warm-houses with *Cucumbers* through the spring and summer. Top-dressed with loam and manure the plants in house now in bearing which were planted in September. Looked over *Grapes* in *Grape-room* to remove decaying berries, but the loss from this cause is very slight. The room is kept at a temperature of 45 degs. to 50 degs. by a hot-water pipe being run through. Moved a lot of potting soil to open shed to get ready for potting. Top-dressed inside borders with late siver, a mixture of turf-loam and the Patent Silicate Manure being used for this purpose.

5271.—*Cider refuse*.—As there is more or less plant nutriment in all vegetable matter, it is quite reasonable to expect that well-rotted cider refuse contains a certain proportion, but how much or how little I cannot say. I should not, however, object to use it as a substitute for leaf-mould if it did not contain any *Apple-pips*. If there is no longer of the pips giving you a crop of young *Apple-trees*, I know of no reason why you should not use it, especially as you say it is reduced to a black soil.—J. C. C.

— I think you will find this a fairly good substitute for leaf-mould, though, of course, not quite equal to it. Mix a little lime and soil to destroy germs of fungi.—J. C. C.

5290.—*Mistletoe*.—I thank "Mr. H. Gibson" for his kind remarks about my note upon the above. I do not know for certain, but I believe that Messrs. R. Smith & Co., of Warrington, Messrs. Cranstall & Co., Ltd., and Mr. Watkins of Bradford, would supply Mistletoe berries in kind. A series or two kept in water will sometimes ripen sufficiently for ornamental. There can be no harm in trying this plan.—F. C.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful flowers and good fruits and vegetables for drawing. The drawings to make will be engraved in the best manner and will appear in due course in GARDENING ILLUSTRATED.

* In cold or northern districts the operations referred to in under "Garden Work" may be done from the middle of a fortnight later than is here indicated with equally good results.

INDOOR PLANTS.

CINERARIAS.

The improvement in the flowers of Cinerarias has been very marked during the last twenty-five years, as they are now much larger, the petals broader, and the form more symmetrical. While there has been this improvement in form, it is somewhat remarkable that there has not been any new colours of a definite character added. This is the more noteworthy because in nearly every other florist's flower great advances have been made in this direction. With respect to the increase in the size of the flowers, I do not find it to be any gain. What is gained in size is lost in symmetry, and added to this is a loose and ungainly plant that no amount of good cultivation seems to improve. I am alluding to the Continental strains of this flower which are sent to this country as superior to any other strain. For three years in succession I grew a strain obtained in this way, and although plenty of the plants produced flowers 3½ inches and

of April is the season when the plants should be at their best. In former times the bulk of the plants did not go out of flower until it was quite safe to turn them out-of-doors in some sheltered corner to ripen their seed, but the practice of modern cultivators has altered a good deal in regard to the time the plants are had in bloom, and this has a tendency to lower the merits of the flowers. Next to this, as I have incidentally remarked, rich feeding is decidedly injurious, especially during the early stages of growth.

LIQUID MANURE of any kind, until the plants have been put into the pots in which they are to flower, should not be given. As a matter of fact, these pots ought to be full of roots and the lower-stem rising before any liquid is given. As regards soil, there is nothing better for them than three parts good mellow loam, one part leaf-soil, and a good sprinkle of coarse sand. In a compost like this the plants will produce good heads of flowers if they are not subjected to more heat than is good for them. The cold-pit is the proper place for Cinerarias, while frost can be kept from them by the use

A good type of market Cineraria.

more across, the petals were so loosely arranged that it was difficult to find a well-shaped flower, and besides this there was a great want of variety in colour. All points considered, what is known as the Covent Garden strain (see illustration), is the most useful to grow for conservatory decoration. The plants are of good habit and they throw up large heads of perfectly formed flowers. The variety of colours is also great, and a large and well-proportioned head of flowers can be obtained from a rather small plant. The average English strain produces much larger flowers than the Covent Garden, but in the hands of a good many cultivators the plants are made through rich feeding to produce such large leaves that the effect of a nice head of flowers is spoilt owing to the larger proportion of foliage. There is another part of the management of the present time which tells against the possibility of securing shapely plants. I allude to the too general practice of getting the plants in flower early in the season, which necessitates the stock being brought on in a closer and warmer temperature than is good for them. The middle of March to the middle

of nuts, as they like to be near the glass and on a bed of coal-ashes. As they are very tender they should be taken to a heated structure when there is danger of severe frost, but not otherwise. It is hardly necessary to grow named varieties now that such excellent strains are to be had, as if the seed is obtained from a good source, varieties equal to the named ones may be had. In raising a stock of plants from seed there is a tendency at the present time to sow too early when large plants with good heads of flowers are required. If a few are required to flower early, the seed may be sown about the middle of May, but plants that are required to bloom at their proper season should be obtained from seed sown a month later.

J.

5246.—**Veronicas in pots.**—These are amongst the easiest of plants to manage, and they succeed admirably in a greenhouse temperature; in fact, on the south coast they are planted out, and left summer and winter, growing in large bushes, and forming a splendid sight when in full bloom. They are also of

excellent habit, branching out regularly, and growing in the exact outline of trained specimen plants without a single stick or tie. *Veronica Traversi* makes fine bushes, as do most of the other sorts, but unfortunately they are not hardy enough to stand very severe frost, and get cut down or much disfigured, consequently they can hardly be recommended for permanent planting out-of-doors; but they do best outside from May until October, when several kinds will help to keep the greenhouse gay for some weeks, as they flower freely in the autumn.—*J. G. Gosport.*

PROPAGATING PLANTS.

There may not be in many cases, especially with amateurs, sufficient room in a few weeks to do all needful propagation, what with bedding "stuff" and other things, to keep the proper supply of plants for pot-culture. Anything, therefore, that can be attended to at once should not be delayed. The present is, for instance, a very suitable one for propagating

CARNATIONS for next autumn and winter flowering. Where any have been struck in the autumn, those now put in will form a good succession to them, the former flowering in early autumn. The cuttings are not always fit to take off at one time, but this will not matter, being rather an advantage than otherwise, two, three, or four batches being the best to secure a continuance of bloom. I am more impressed than ever with the excellent properties of *Winter Cheer*. It is a worthy companion to *Miss Jolliffe Improved*, whilst as a white, *Mrs. Moore* is strongly recommended. I have now got a batch of cuttings of those sorts striking, most of which were lateral shoots pulled out at the junction with the main stem; others were taken from leading growths simply because we were short of them. These cuttings have been placed five or six into 3-inch pots around the sides of the pots and plunged in a gentle bottom-heat frame of about 75 degs., with a temperature in the house at night of 60 degs. to 65 degs. This treatment will, I think, suit them very well. Previous to taking the cuttings the old stools were in a night temperature of 50 degs., rising by day, so that the difference for the cuttings is not any too much. The soil used for striking is about half Cocoa-nut fibre, the rest loam and silver sand. Sheets of glass are placed over the frame, but there is a fair amount of ventilation on each side through it not fitting closely. I find the crickets a bit troublesome in eating the cuttings; if this continues I shall give them some growths from outside to nibble at, and then kill them, if possible, with hot water. As soon as the cuttings are struck they will be gradually hured to the usual atmosphere, and soon afterwards be taken to a somewhat cooler house. Pipings from Pinks for pot culture can also be put in now, not that there is any time lost, but I find them strike better before the weather gets much brighter. A few old stools of

BOUVARIAS should now be placed in heat to start the plants into growth for early cuttings. Those who have not thus far taken any note of *Priory Beauty* and *Mrs. Robert Green* will do well to work up a stock of them. They have in either case the free habit of *Vreelandi*, the former a soft-pink, the latter more of a salmon shade. *Zonal Pelargoniums* for next autumn and winter-flowering should be struck now, or as soon as possible. With these the better way is striking singly in 2½-inch pots to avoid any after check. A vinery at work will answer well for these cuttings, failing a pit that is suitable for them. What has to be guarded against in this case is an excess of moisture, more so even than in that of striking cuttings from bedding varieties which have been resting more through the winter than the others have. The earliest flowering *Salvias* can also be propagated now; these will do well where the Carnations are being struck. Of these, *Salvia splendens* and its variety *Braunli*, a dwarf form, and *S. Bethelli* (rose and white), with *S. Heeri* (scarlet, now in flower) are about the best for autumn and winter. *S. gomeriflora* being more of a spring-flowering variety, propagation should be deferred for a time. Where the old-fashioned scented-leaved *Pelargoniums* are esteemed for their fragrance, and any demand is anticipated for cutting them, it is very advisable to set about the propagation of these also, so as to

keep up the stock. In my own case I have struck a good number of cuttings during the winter on a ledge at the back of some *Gardenia* and *Ixora* pits. This has been just the place for them, hardly a cutting failing. Now onwards they will strike easily enough in a fair warmth; the warmth of ainery that is fairly advanced will suit them.

CURTAINMENTIONS.—If the usual stock has not been already secured, some more cuttings should be put in as soon as fit. In doing this, do not lose sight of the usefulness of the early autumn varieties as represented by the *Des-grange* family, *La Vierge*, and others. In any case, if the old stools are still on hand, it will not be advisable to cast them aside just yet unless the pits and the room are really needed at once. Where early plants of *Fuchsias* are likely to be wanted, some old stools should at once be put into a good warmth for cuttings, these being taken off before they get too long and then struck in nearly all sand. Only the most reliable kinds should be looked to for early flowering, for which Mrs. Marshall is scarcely beaten yet in its way. Double *Primulas* should now soon receive attention; it may be possible that the plants are still giving a fair amount of bloom. Even if this be the case, a few should have all the flowers cut off them and then be given a little more warmth; then in a week or two the cuttings will be fit to take off. In the propagation of these, an excess of moisture has to be guarded against as much as anything. Given a fairly warm house, say 55 degs., to 60 degs., they will strike very well in such a place upon a moderately dry bottom; a hand-light, with a movable top, will make a good place for them. Those who cannot—as a rule, strike them satisfactorily should adopt the layering process, first trimming off the elder leaves and then filling up close to the young growths with Cocoa-nut-fibre and sand, or, failing the former, some finely-sifted leaf-soil will answer the purpose. In either case, this newly-added soil should be kept moist to encourage root-action. H.

7278. — **Solanum capsicastrum.** — I would advise "K. J." to grow his *Solanum* on in pots, up till danger of frost is over, then plant out in a sunny spot, and keep well watered. If he has already cut his young plants down close to the pot, they will soon push out a thicket of young shoots from the base. After these have grown a few inches they should be pinched, to induce the formation of a number of side shoots, and if kept under glass until the end of April, or early in May, according to locality, they will be well furnished with shoots that will quickly be covered with flower. They must not be pinched after they are planted out, as the object is to get the crop of berries set as early as possible, or else they will not ripen in time to be of any use. Early in September they may be lifted and potted, placing them in a shaded place for a few days, until they will bear full exposure without flagging, when they may be put on shelf near the glass to finish colouring the berries.—J. G., Gosport.

7265. — **Panacratium fragrans.** — These plants are easily entitrated, and should be freely grown with a good supply of water, and when the bulbs are well formed the plant enters into its season of rest, and at that time does not need much water; but the leaves should not be allowed to flag, and the plant ought to be kept in a greenhouse temperature. When the plant has well rested after flowering, and is ready to start into growth again, water freely, but do not repeat unless it is absolutely necessary.—J. D. E.

— After flowering the plants should be encouraged to make new growth by affording them heat and moisture. A temperature of not less than 60 degs. by night, with a rise of 10 degs. during the day, should be provided. Now is a good time to repute if the roots are not in good condition, but when the drainage is perfect and the plants in pots 8 inches to 10 inches in diameter, re-potting should only be practised seldom. This *Panacratium* flowers more freely when the roots are a bit cramped, providing they are in a healthy state. A compost of three-parts fibry loam, with one of peat and leaf-mould, with a free admixture of a little silver sand and charcoal to keep the whole

porous, should grow this plant well. When growth is being made give abundance of liquid-manure to the roots to promote a healthy, vigorous growth. Syringe the foliage twice daily with tepid water to keep the leaves clean and free from dust. When the leaves have reached their full size gradually withhold water for a time, so as to give the plants a rest, but do not allow the foliage to wither in consequence of dryness at the roots.—S. P.

PERPETUAL-FLOWERING OR TREE-CARNATIONS.

The Tree-Carnations, so called from the tall struggling form that the old varieties formerly grown naturally had, have been superseded by a

A Tree or Winter-flowering Carnation.

race of plants that possess a bushy habit of growth, with free and continuous disposition to flower, so that with a sufficient number of plants they may be had in bloom all the year round. Carnation flowers are justly held in high estimation for bouquets and other arrangements of a like nature. Perfume, enduring properties, and beautiful colours go to rank them amongst the most attractive of all flowers. They can be raised in different ways from seeds, cuttings, and layers. The seeds should be sown about the beginning of February in shallow pans or boxes, in sifted loam, with some leaf-mould and sand added. Just cover the seeds with soil; stand in a temperature of 55 degs., or 60 degs., and they will soon vegetate. Then place near the glass and give air in the day so as to prevent the growth from being drawn; as soon as the young plants have got two or three leaves each put them singly into small pots, using soil similar to that in which the seeds were sown. The increase of sun-heat will now do away with the need of fire-heat, except when the nights are cold. When the roots have made some progress the plants should be moved to a cold frame and aired freely, so as to prepare them for planting out in the open ground towards the end of May. Choose

an open place where the soil is of a good description, and dig in some rotten manure and leaf-mould. Put the plants a foot apart, with a little more room between the rows, pinch out

the points, otherwise they will not be furnished with sufficient shoots, and give water in dry weather. In September lift them and put in 6-inch or 7-inch pots in good rich loam, to which add a little leaf-mould, rotten manure, and sand; water moderately, and stand in a light house or pit near the glass. The plants should now be furnished with from four to half-a-dozen shoots each; these will push up flower-stems through the autumn, and come into bloom sooner or later according to the warmth they are subjected to. When the flower-buds are prominent a temperature of 50 degs. in the night will accelerate their opening; such as are required for later flowering must be kept cooler. After blooming the plants ought to be again turned out in May, or later in the case of those that have been kept back for late spring flowering. In all cases cut out the old bloom-stems at the bottom as soon as the last flowers are over; if this is not well attended to with the young plants, as well as with the old and large, they get into a tall unsightly state, and are much less manageable. When out

IS THE OPEN WOUNDS they must not want for water or be allowed to suffer through the ravages of aphides. Again, in September, take up and put them in pots 7 inches or 8 inches in diameter, and treat as in the preceding season. A portion of the plants this second season should not have their shoots stopped; these will come into bloom early in the autumn, and be succeeded by the remainder that have had their shoots pinched back about July.

CURTAINMENTS should be struck in autumn, several together in 5-inch or 6-inch pots filled with a mixture of sand and loam. Stand them on a slight hot-bed, and if kept shaded and moist they will soon root. Then they must gradually be subjected to more air and a lower temperature, after which put singly in small pots, and keep them through the rest of the season in a frame or pit. Winter out of the reach of frost; stop the shoots and turn them out in a bed in May, and treat subsequently as recommended for the plants raised from seed. Layering should be carried out in the summer, about the same time as in the case of the exhibition varieties of Carnation. Aphides are often troublesome, but can be got rid of by fumigating with Tobacco or dipping in Tobacco-water. Mildew sometimes affects them; for this dust with flowers of sulphur. There are now many good kinds, a list of which can be found in most trade catalogues. B.

7276. — **Gloxinia bulbs.** — Tubers of these plants may become "soft" in two distinct ways—one when they have been touched by frost, when as soon as they show they are "soft," and, in fact, rotten, and for this there is no remedy. Again, if kept too dry and warm, they become limp, and shrivel to some extent; but unless too far gone this does no great harm, though of course it reduces the vitality, but if surrounded with moist Cocoa-nut-fibre and kept moderately moist they will soon plump up again. When not thoroughly and gradually ripened off they are much more liable to shrivel in this way. The best way to keep them is in half-moist Cocoa-nut-fibre in a temperature of about 50 degs., and then if sound and good to begin with they will remain plump and firm throughout, and start away strongly in the spring.—B. C. R.

Gloxinia bulbs should not get soft at any time. Probably the bulbs are rotten, or if badly ripened they might shrivel if kept in a very high temperature. Shrivelled bulbs seldom do much good afterwards.—E. H.

— These generally get a little soft when at rest in winter; but it is a mistake to allow them to go too much in this direction. The best way to treat them is to place the pots on their sides in a hot-house, not a greenhouse, and give no water until it is time to start them again in the spring.—J. D. E.

— I am afraid your bulbs have either been frozen or have got dry rot through being kept much too dry. They certainly ought not to be sown. The consequence is death, and supposing my opinion to be correct, the cause and cure suggest themselves. Put them up soon, and in future keep them in sand that is not sufficiently dry to perish them.—P. U.

5273. — **Cinerarias.** — I had a case of the leaves of *Cinerarias* curling up badly in a house 50 feet long quite filled with the plants, and was surprised at it, as such a disaster had never occurred before in a long experience. I thought it must be mildew, but some of the leaves, badly curled inwards, bore no traces of the parasite, and they were quite free from insect pests. Another thought occurred to me.

We were experimenting with some new fumigating material, and I put that down as the cause, only to find out I was wrong again. At last it occurred to me that it must be the cold winds acting upon the soft, delicate tissues of the leaves, and this it undoubtedly was. Too much air had been admitted on cold days, and ever since, when cold winds are blowing, I open the ventilators only at the highest point, and that but sparingly. The result, no curling of the leaves.—J. D. E.

Cineraria-leaves very often curl up when attacked with green-fly, and if this was the cause sulphur would not be the remedy, though Tobacco-powder would, or the plants may be dipped in a solution of Sunlight soap, about half a tablet in 3 gallons of water, used warm, say 50 degs.—E. H.

5266.—**Coelus-cuttings.**—Any bits of these plants—side-shoots or tops—will root in a few days in sandy soil in a brisk hot-bed, or in a stove or propagating-house, in February, March, or April. They are, indeed, about the easiest things to strike that could be mentioned, given only a brisk and moist warmth. The cuttings will root all right in sand or Cocoa-nut-fibre only, but a mixture of loam, sand, leaf-mould, and Cocoa-nut-fibre in equal parts is best.—B. C. R.

Coelus-cuttings will strike any time in a temperature of 55 degs. The best time for working up stock is in spring, from the middle of February onwards till May, whenever cuttings can be obtained.—E. H.

5274.—**"Geranium" - cuttings.**—The young growths now made in a greenhouse will do very well indeed to put in as cuttings, and they will strike root freely and well in a temperature of 55 degs.; but a moist atmosphere, which would do admirably for other cuttings, will not do very well for Zonal Pelargoniums, which, I presume, is what is intended by "Geraniums." The old stools will start freely again in the same temperature, or in a lower greenhouse temperature. Both the cuttings and the old plants will do admirably for bedding-out in the summer.—J. D. E.

Yes; the young growths you mention will root freely and form suitable plants for bedding out next summer. You will find it an improvement if you can stand the pots containing the cuttings upon a hot-water pipe or flue, seeing your temperature is but 55 degs. These cuttings will bear a lot of heat at the root, but must be shifted as soon as rooted. The old stems will break and be almost as useful as if not cut down, and will be more bushy.—P. U.

Young shoots of "Geraniums" will strike now in a night temperature of 55 degs. to 60 degs, and make good plants for summer bedding if helped on for a time in heat; after being potted off the old plants would make new growth, and would blossom well in summer. If potted on they will do well for filling vases or for centres of beds.—E. H.

5279.—**Starting Begonias.**—I saw a very nice bed of Begonias last year obtained from tubers that had filled the same spot the season previous, and which had kept all the winter in a box filled with dry soil, and this was placed on the brick floor of a coal-cellar. Early in April the lady got other boxes and after filling them with soil put the tubers in them 6 inches apart. The boxes were then taken to an upstairs room and placed in front of the window where they remained until the end of May. Treated in this way the tubers made a display equal to many others that had had the advantage of greenhouse treatment. You, however, with your frames might do better still. The first week in April make up a bed of soil in a frame and plant the tubers in it, give no air until growth appears, and cover the glass at night with a thick mat to exclude frost.—J. C. C.

Do not be in a hurry to start Begonias intended for the open air. March will be quite time enough. They will start themselves when the season comes round if placed in a box and the soil just moistened afterwards. They will do in the cold frame if covered at night, so that frost cannot enter.—E. H.

CROTONS AND THEIR CULTURE.

In answer to "B. H. J." and others, we here give an article on the subject.

PROPAGATION is not at all difficult, where a close pit or propagating frame is at command, with a brisk bottom-heat to induce the cuttings to strike root quickly. If young plants, for table decoration or other purposes for which they are to be used in a small state, are required, select cuttings with clean, straight growth, well-developed and finely coloured foliage, and single stems. If the object is to grow plants for specimens quickly, the better plan is to choose cuttings of a larger size with three or four growths or even more; these when struck will make a

better beginning from which to start a specimen plant; indeed, by making a good selection for this purpose a season may thereby be gained. My practice is to throw the cuttings into a tank of water for an hour or two when first severed from the plant, in order that they may absorb as much moisture as possible. When inserting them make them firm in the pots; and if of large size a support or two may be of service. I generally find them rooted and fit to withstand ordinary stove treatment in a month or six weeks.

CULTURE.—As soon as the young plants have filled their cutting-pots with roots they should be shifted into larger sized pots. This ought not to be overlooked, for if by chance they happen to be allowed to suffer from want of water at this early stage of their existence, they will often succumb to it, or, perhaps, lose some of their leaves, and this they should not do to any extent if due attention is paid them. In fact, it is essential, in the case of small decorative plants, that they should be clothed with foliage down to the pots. Those intended for specimens should be again shifted as soon as they require it, in order to maintain a free, vigorous growth. I find them to do well in a compost of good animal silicious peat (such as one would select for Ferns) and turf loam in about equal proportions; to this I add a fair amount of leaf-mould and some half-inch bones or lime-meal. Charcoal is an assistance in the case of specimen plants if the loam is of an adhesive character. A liberal supply of silver sand should be added, and abundance of drainage should be given, so that the plants can always be freely supplied with water, of which they can take a good deal. They also revel in a moist atmosphere and a maximum stove temperature. The syringe should at all times be plied vigorously among the foliage. I use it at this season of the year at least three times daily; later on, when the weather is hot, another turn will be given them at nightfall. Under this treatment ordinary tying material soon becomes rotten;

contrary, the points of all the shoots should project, in order to give as much diversity as possible, and admit light to the young leaves. Some kinds do not make much lateral growth, and where this is the case pinching must be frequently resorted to. Shading is unnecessary even during bright sunshine, unless the weather is excessively hot, and it should not then be used for any length of time. The best plan is to arrange the Crotons so that they do not receive the shade that is necessary in the case of most other ornamental foliageed stove plants. Their rich colours will then be intensified.

INSECTS.—Crotons afford a refuge for insect pests, against which an incessant war must be waged if the cultivator wishes to produce plants that will do himself credit. In the case of mealy-bug, brown and white-scale, I use nothing but the Chelsea Blight Composition. Other insecticides are doubtless also effectual, but I adhere to the one that I have found from experience to be so. For black and white-thrips fumigation will answer, if repeated two or three times in rapid succession. Red-spider is also a great enemy to Crotons, and I have found another insect closely allied to it, but even smaller, giving almost endless annoyance for some time, ransing the young leaves to fall before they were half grown. As a remedy for this and red-spider, I was advised to keep a bag of soot in the tank from which the water was drawn for syringing. This had the desired effect. Having found this remedy so beneficial, I make it a practice to always keep a small quantity in the tank from which the water is used both for watering and syringing. Soot is not only valuable in a manorial point of view, but a great deterrent to many insects, and even the fronds of the tenderest Fern are not injured by it. I would strongly advise anyone to try the soot-bug remedy and watch the result.

VARIETIES.—There is an immense number of sorts now in cultivation, very many of which are so far inferior to others as to make their

Croton "Baron Franck Seillière."

my practice, therefore, is to use tarred string, which lasts longer. In training specimen plants I have found a pyramid form to be about the best, and in my opinion preferable to that of a bush. In the pyramidal form the height ought to be about one-fourth in excess of the width. This shape, I think, displays their beautifully marked foliage to the best advantage, but a too formal outline should not be adhered to; on the

growth unnecessary. The following are all distinct and handsome kinds: C. angustifolius, C. Crown Prince, C. Baron Franck Seillière (here figured), C. Disraeli, C. Evansianus, C. Hawkeri, C. Johannis, C. majesticus, C. picturatus (Princess of Wales), C. Queen Victoria, C. roseo-pictus, C. undulatus, C. velatus, C. Warfield, C. Weilandii and C. Williamsi.

H.

THE KITCHEN GARDEN.

EARLY BRUSSELS SPROUTS.

THE value of a few rows of early sprouts is great where a variety of choice vegetables is required. I am well aware that some persons object to early sprouts before the frost has mellowed them, as it is termed, but much of this is owing to the method of serving or cooking and to the way they are grown, as, though we have not too much praise to bestow upon cooks in general in the way of making the best of the garden products, to a certain extent want of space, insufficient moisture, and feeding are at times the cause of poor vegetables. Early sprouts are at times strongly flavoured, often through being boiled too long in one lot of water. If when partially cooked the sprouts are given fresh boiling water the strong flavour will be removed and a better colour imparted to them. Of course, it is a little more trouble. Not only sprouts, but many other vegetables need similar attention. By sowing early it is also objected to that the sprouts are too coarse or large. This can be avoided. I do not like large sprouts, though they seem to be much appreciated by the market people. Large sprouts soon fill the basket, but are not so good as a smaller, hullet-like growth—hard, and without waste. To get a medium-sized sprout the grower should eschew the sorts recommended for size or length of stem; they are no doubt profitable to the large grower or for exhibition, but for the latter purpose they are now even less grown. When Brussels Sprouts are served at table a miniature Cabbage is not expected, as it is impossible to serve these large kinds to the best advantage, so that in private gardens much of the delicacy is lost when large coarse kinds are grown. There is very little trouble in securing a few early plants if seed is sown at the end of January or early in February. I prefer to sow on a mild heat—that is, a bed made up with fresh leaves early in the year and allowed to settle down before sowing the seed. Others may not have similar accommodation, and may only require a small number of plants. In such cases a single box of seed may be sufficient, but with the latter greater care is required, as often the smaller quantity, if placed in excessive heat, is brought on too rapidly, with the result that the plants are weakly from the first and cannot give a fair return. When sown in cold frames the plants are sturdy, and better able to withstand our cold winds in the spring. I have previously advised a dwarf variety, and for years have grown Paris Market, a dwarf early, small, solid sprout of good flavour, but no doubt there are others equally suitable. Another important point is sowing thinly, as there are more plants ruined by thick sowing than anything else. Early transplanting is also necessary, lifting with as much care as possible. In exposed positions much can be done in the way of shelter by drawing deep drills before planting out, in all cases using a trowel to preserve all the roots possible. Another equally important point is deeply digging ground with plenty of decayed manure. During the early autumn months in case of drought, a good soaking of water or liquid manure occasionally will do much to remove the strong flavour often objected to. I would also advise ample space at planting; a yard between the rows is none too much, and 18 inches or even 2 feet between the plants.

G.

Sowing Cauliflowers.—Many people now rely upon plants raised in the beginning of the year for their principal supply of early Cauliflowers. This being the case, it is now time the seeds were sown. The plants must not be hurried on, thinking to make up lost time, as if so they will be useless, as instead of forming neat little heads, they will turn in prematurely, or, as gardeners say, "lunton." It is also advisable to sow one of the now recognised early varieties, such as Veitch's Early Forcing or Snowball, and to follow on select either Early London or Dwarf Erfurt. Walcheren might also be sown. If a forcing variety is needed to grow on in pits, Veitch's Forcing is very good, although with the late kinds of Broccoli now in commerce, these with the earliest Cauliflowers bridge over the season. That is, if the Broccoli should not be killed by frost,

The seeds should be sown thinly in shallow boxes of light soil, and to ensure quick germination place the box in a gentle warmth. As soon as the seedlings are well through the soil remove to cooler quarters near the glass, but not where they are likely to become starved through either too cold or draughty quarters. Watering must also have careful attention to prevent the seedlings damping off. Directly they are large enough put off into 4-inch or 5-inch pots. The soil also should be substantial, three parts loam to one each of leaf-soil and pulverised horse-manure. Keep close until established, afterwards removing to a greenhouse shelf, eventually placing in a cold frame. The plants may also be pricked out into low light frames. In this case place a layer of rotten manure to the depth of 2 inches on a hard bottom, and above this the same depth of holding loam and a little leaf-soil, into which prick the plants not less than 4 inches apart.—G.

POTATOES FOR SHOW.

THOSE who ask for the names of the best Potatoes to grow for show, I notice want them chiefly in the months of July and August. These early dates somewhat limit the range of choice of kinds, as in neither case are all the sorts available so early in the season. For the first mentioned month the earliest varieties only will do under ordinary treatment. The best of these of kidney shape is Rivers' Royal Ashleaf. This is a very handsome Potato, and the tubers are of uniform size. It is in every way preferable to Myatt's Ashleaf, as the tubers are not so pointed. Ringleader is another first early kidney that is as good for table as it is for exhibition; the tubers are not very large, but they are uniform in size and they are conspicuous for evenness of outline. The earliest round variety is Sharpe's Victor, and if care is used in selecting the tubers a very handsome dish can be had. The cultivator must, however, be prepared to grow a larger number of stools to select from than is necessary in the case of some other sorts. Dalmahoy is an old sort that is still retained by a few exhibitors of early Potatoes, as it ripens off fairly early, and the tubers are of medium size and even in outline. It is a white round sort with shallow eyes. Should larger sorts be wanted than I have mentioned, Beauty of Hebron and Early Puritan may be selected; but under ordinary treatment the tubers will not be ready before the end of July. Those who require one dish of round and one of kidney shape should grow two of each, so to have a choice. They will find it a good plan to cover the sets with rotten tan or leaf-soil 3 inches in thickness, as the tubers will come out clearer from either of these materials than from ordinary soil. Those who do not want to exhibit before the middle of August have a much wider choice of sorts, as the second earlies will be available. Amongst these The Dean is a handsome purple kidney, and unsurpassed in its colour. Covent Garden Perfection is a white kidney of a refined appearance when well grown, as the tubers are of fair average size, without the slightest trace of coarseness. International Kidney grows to a large size, and with care in selecting can be arranged very conspicuously on the exhibition table. Its size and even outline are very impressive with some judges; but I would not include it in my selection unless I felt pretty sure that size stood a better chance of winning than high table quality in smaller tubers. Three good round second earlies will be found in Sutton's Seedling, Snowdrop, and Reading Russet. The last named has rather flattish tubers, which are of a dull-red colour. This sort makes a very telling dish in a collection of three round varieties. At a country show at which I was judging last November, I made note of the following sorts as being exceedingly telling dishes: Grampan (red), Main-crop Kidney (white), Chancellor Kidney, Schoolmaster (round, white), and Vear of Laleham (round, purple). J. C. C.

5270.—**Tomatoes, &c., in a greenhouse.**—I can quite sympathise with an amateur who wishes to grow Tomatoes and Cucumbers in a small greenhouse, but the question arises, what else does he expect to grow? The Tomatoes and Cucumbers would do best

trained to the roof of the house, and if the seed is sown now it would require a much higher temperature than greenhouse plants would thrive under to get anything like good growth into the Cucumbers. Three plants of each would quite cover the roof of the small house, and if light was so much excluded by the leaves of the Cucumbers and Tomatoes the plants underneath would do little good. I would recommend sowing the seed of the Cucumbers and Tomatoes about the first week in April, and by the time the plants covered the roof the greenhouse plants would do well out-of-doors, and the house would be free to give them a hot-house temperature, and the entire glass-roof might be covered with the growths of the occupants of the house. It would never give satisfaction to grow Cucumbers in a greenhouse with greenhouse plants.—J. D. E.

By exercising great care you may grow a few Cucumbers if you plant them at one end of the house, but in such a small structure you will find it get so hot in summer that the Cucumbers will get infested with red-spider, unless you shade that part of the house and keep the Cucumber-plants well syringed two or three times a day. The Tomatoes will do right enough if you give them plenty of air in hot weather. Five Tomato-plants on a single stem, and two Cucumbers on each side, are as many plants as you require. The Cucumbers should have the coolest end if you want them to hold on all the summer.—J. C. C.

Better be content with either Cucumbers or Tomatoes. It may be possible to do unmy things which it is not wise to do; besides, the house is too small for two such crops. As an experiment the thing may be done, but it will pay better to keep to one crop. The two plants require different treatment, and except in experienced hands the chances are that one or both would fail.—E. H.

It has been frequently stated that these two subjects do not do well together in the same house, the former requiring free ventilation and to be kept moderately dry, while Cucumbers luxuriate in a warm, moist, and close atmosphere. If you must grow both, plant eight Tomato-plants on one side, keeping each to a single stem, and training them up near the glass, and three or four Cucumbers on the other. But you will find it far more satisfactory to grow one or the other, and not both.—B. C. R.

5267.—**Vegetables for show.**—To obtain a few early roots sow Beet and Carrots end of March on warm, deep soil. Early Horn Carrots and Turnip-rooted Beet may be sown a little earlier. Sow Parsnips end of February. Something must be allowed for latitude, as in a cold district the dates given above would be rather too early. I am assuming the show would be held some time in August, as this is the usual month for holding country shows. If the show is later in the season the Beet and Carrots need not be sown before middle of April, as mere size is not so important as well-grown roots, good both in colour and shape.—E. H.

You must sow Parsnip seed in February in open weather, and Beetroot and Carrot in the second week in April. Dig and manure the ground at once, stirring up the bottom soil to a depth of 18 inches. All the subjects named should be thinned out as soon as the plants are large enough, so that they stand 18 inches apart in the rows. All of them will be benefited if given root-water once a week in dry weather if the soil is at all poor. You must, however, be guided by the condition of the foliage in applying stimulants, or you will get more leaves than roots. If you find the foliage getting too vigorous, leave off applying stimulants.—J. C. C.

Scarcity of Lettuces in early spring.—After such severe weather as we have just experienced there may be a scarcity of Lettuces during the next two or three months, as even those plants stored or planted out in cold frames when not much frosted have in many instances suffered from damp, as it has been impossible to admit light and air. Those who have a daily supply of green salad to send to table will do well to prepare for fresh supplies by timely sowing in frames, choosing an early quick-growing variety of the Cabbage type. A small, quick-ripening kind, such as Veitch's Golden Queen, should be chosen.

This forces readily, and is of dwarf, compact growth. Harbinger is also excellent for sowing in heat in boxes, and cutting in a young state. This system is one that could often be made available in cases of a deficiency, sowing the seed in boxes and cutting in the same way as Mustard and Cress. Of course, the produce is small, but for the salad-bowl it is equally useful, and in the early part of the year much appreciated. For the supply of single Lettuces, a few plants of the varieties named pricked off into boxes or in a frame soon turn in.—W.

VEGETABLE MARROW CULTURE FOR MARKET.

VEGETABLE MARROWS constitute one of the principal summer crops in the immediate neighbourhood of London, and, where soil and other conditions are favourable, they are very productive. They require, however, a rich and substantial soil, liberally manured, and also one that does not readily become parched in summer; therefore light and dry soils are not so suitable for them as such as are heavier. Early in March hot-beds are erected for producing Vegetable Marrows, Cucumbers, Celery, and other plants from seeds, the Marrows being either sown thickly in pots or pans of common soil plunged in the beds, or broadcast on a bed with a few inches deep of soil placed over the fermenting material. As soon as the plants show two rough leaves they are pricked out into other beds or into pots. The usual method is to prepare a series of frames set on slightly heated hot-beds; on the surface of these to place a few inches deep of soil, into which plunge 6-inch pots, filled with common garden mould to the brims, as thickly as they can be stowed together. Into each of these pots two Marrow plants should be dibbled and here they should remain till planting-time, hardening them off by gradual but increased exposure in fine weather. The first plantation is made out of doors during the first week in April, but the plants make little progress until the end of the month. The ground is marked off in lines about 10 feet apart, and each plant is 6 feet or 8 feet asunder in the row. Where each is to be planted, a hole about 20 inches deep, and 2 feet or 2½ feet wide, is dug out and filled with fermenting manure, which is covered over with the soil that has been thrown out in the excavation. Here the plants are planted, the contents of one pot being put in every ridge, and covered over with hand-lights or large clishes. A little earth is at first drawn around the base of the lights, so as to keep all close and free from cold currents of wind, and, in the event of frosty or cold windy weather setting in, mats or litter are also placed around and over the lights. Excited by the heat from the fermenting manure beneath them, and protected from cold overhead, they are almost as snug as in a hot-bed, and consequently they soon take kindly to their new quarters, form fresh roots, and begin to grow. When this is the case the lights are tilted up a little on the south side by means of half bricks or small flower-pots, during favourable opportunities, but shut up at night. When growth, however, begins to make rapid progress, the lights are left a little tilted up at night, so as not to injure the shoots that are pushing forward, and require more room than is afforded under their little glass-houses, until finally the lights are entirely removed, which will probably be in the latter half of May. This plantation, when it does begin to grow in earnest, grows most rapidly, and from it fruit is generally cut in the first or

second week in June—much certainly depending on the warmth of the season.

LARGE GROWERS have generally from four to six plantations of Marrows, each succeeding the other by a fortnight, so that the last planting is made late in June. The seedlings are all raised on hot-beds, as already described; but I have known instances in which the seeds have been sown in June, in clumps of four, where they are intended to remain permanently in the open fields, and afterwards reduced to two; this plan is, however, a very uncertain one. Until the middle of May the plants are planted out on the manure-pits, as in the case of the first sowing; but less care is necessary for them. Where the supply of lights and clishes is deficient, round vegetable half-bushel baskets are used; but, unless these are covered with mats or litter, in the case of frosty winds the plants beneath them often perish. After the middle of May, lines are drawn on the open fields at the required distances apart, and the Marrows are turned out of their pots and planted in the ground, which received no further preparation than that of a slight digging. If the weather be warm and genial, they generally do well, if cold and wet many of the plants frequently succumb; but the blanks are made up from a reserve stock, which is always at hand to meet such emergencies. Although the distances apart of the first planting is 10 feet by 6 feet or 8 feet, that of the June plantations is 15 feet by 10 feet or 12 feet, and the intervening crops are planted at corresponding intermediate distances.

regards thinning the overcrowded vines; but sometimes the growers mulch the ground with litter, which not only enriches it, but preserves its moisture, prevents to some extent evaporation, and keeps the fruit clean from grit. As soon as the plants begin to bear, every fruit is gathered when it attains a marketable size, no matter whether they are sold or not, for if any were left too long it would tend to render the plant less fruitful. They are gathered three times a week, the gatherers being supplied with fruit-collecting baskets, a stick, and a knife. With the stick they turn aside the leaves of the plants in search for the Marrows, and they are thus enabled to go over the ground quickly, and without much bending of the back. When each gatherer has filled a basket, it is carried to the outside of the plantation, and emptied into a heap, or into large baskets or a waggon stationed there to receive them. The trampling the Marrows seem to undergo in the process of gathering does not seem to injure them much. In August some good fruits are selected and marked by inserting an upright peg alongside of each, and these are allowed to

REMAIN ESTABLISHED THROUGHOUT THE YEAR, when they are cut and placed within frames or in exposed situations before the sun, so as to become thoroughly ripened. They are afterwards placed in a warmer in some of the sheds, to await a convenient season for extracting and washing the seeds. After the middle of September the demand for Vegetable Marrows diminishes; consequently, they are not after that time worth the ground they occupy. Sometimes they are cleared off the ground at once, and at other times they are left until frost completely kills them; but in all cases the land is raked off and carted to the manure-heap before mowing or digging the ground, which is usually planted at once with Coleworts. B.

OUR READERS' ILLUSTRATIONS: White Vegetable Marrow. ForWARDED FOR GARDENING ILLUSTRATED FROM A PHOTOGRAPH SENT BY MR. NORMAN BLAKE, BEDFORD.

Beet "Cheltenham Green-top."

—I am very fond of this variety; indeed, I have often advised its use, but when sown on good land it grows rather too large. I find it best to sow it on rather poor ground. I never saw Beet till the second week in May, and find by so doing that I obtain

The earliest crop is planted on ground just cleared of Radishes and Celery, or, if the Radishes be not cleared at the time of planting, the Marrows are planted in every alternate alley between the beds, thus permitting the Radish crop to be removed at convenience. For the later crops, ground occupied by spring Spinach, Radishes, autumn-sown Onions, Cabbages, or Cauliflowers, forms a good medium.

SPACE between the rows is not lost during the minority of the Marrows, but is cropped in within 2 feet of them with Lettuces, in addition to which there are generally three or four lines of Cabbages or Cauliflowers planted along the centre of the space. Turnips also sometimes form the inter-crop. When the Vegetable Marrows begin to grow, if the weather be dry, little basins of earth are drawn up to them with a hole for the retention of water, of which they get a good supply until their foliage covers the ground, and thus prevents speedy evaporation from it. The plants begin to fruit when the vines are 3 feet or so in length, and continue growing and fruiting until frost, drought, or millew renders them useless. In a dull, rainy season, provided it is warm, they will thrive apace and fruit heavily; but in a hot and dry one they are short-lived and unprofitable. When they are growing pieces of stone or brick are sometimes placed on the advancing vines or they are pegged to the ground to cause them to root at the joints and thus to find themselves increased means of support. No care is, however, taken of them as

just the roots must desired—neither course nor forked. When sown too early or on rich land I do not know of a worse kind for forking and splitting, but, treated as advised, it is all that can be desired. I consider the flavour superior to that of Dell's Crimson and the colour is very good. The Cheltenham Green-top I have now grown for twelve years, and find no other kind to equal it for flavour. This kind originated in one of the large market gardens round Cheltenham, where immense quantities are grown for the milland markets.—S.

5263.—Tomatoes under glass.—Tomatoes may be grown at a considerable distance from the glass, and they will do very well indeed if they have plenty of light and air; but when they are grown so far from the glass, and shaded by Vines or something else between them and the sunlight, they do not succeed well. The best crops of Tomatoes are obtained when the plants are within a foot or even less of the glass roof; in fact, the nearer to the glass the better, if the plants do not run into immediate contact with it.—J. D. K.

—Tomatoes will do very well trained a foot from the glass, or any greater distance if not shaded by any other plants.—E. H.

—The nearer these plants are to the glass the better, provided the leaves do not actually touch it. If the wires or rods are fixed 8 inches or 9 inches from the glass that will do nicely.—B. C. R.

Brussels Sprouts "Dwarf Gem."—This kind, under proper conditions, will bear soil, and when got out early, has stems about 18 inches in height, and these are packed from bottom to top with those set solid. Sprouts that are not so strong-flavoured as are larger ones.—D.

FRUIT.

KEEPING LATE GRAPES.

The accompanying illustration represents a capital glass which is used by Mr. Stanton, of Park Place, Henley-on-Thames, for keeping Grapes. It is a great improvement on the bottles generally used, and is very cheap. The receptacle is made of clear glass, and having a wide mouth, water can be easily added from a small watering-can as required without the trouble of taking it down or removing the Grapes. Having square sides, too, it may be moved along in the racks to suit the size of the bunches, as there is no need to fix it, the rails being just sufficient distance apart to admit the bottles between, and fixed at such an angle—as illustrated—that the bunches hang clear. The weight of the bunch will press the increased end of the stem against the upper side of the bottle, and so prevent its slipping out. It may be urged that as Alicante and Lady Doyne's—two of our best late Grapes—often produce their best bunches near the main stem of the vine, such bunches could not be kept in these bottles through the stem at the base being too short; but there is no difficulty in this, as the Grapes will keep very well if the terminal end of the shoot be inserted in the bottles. It is always best to leave about 18 inches of stem beyond the bunch when the Grapes are cut, as otherwise the berries are apt to crack through absorbing too much of the water when first stored. It is well also to cut off the immersed end about once in three weeks to maintain a free passage for absorption.

H.

FRUIT GARDENS.

AMATEURS in very many instances display a lamentable want of system in their arrangements of fruit-trees and bushes, and not a few private gardeners are content to plant in a haphazard fashion. Vegetables and fruit can be grown together with a fair amount of success, but in most instances the results would be far more satisfactory if the trees and bushes were grouped together, the vegetables also having their quarters wholly given up to them. The fact of the gardens being on a small scale, or say half an acre or thereabouts in extent, does not materially alter the case, unless to strengthen my arguments in favour of some system of arrangement other than that which generally passes for such. If either standard or half standard fruit-trees of any kind are dotted about the garden, these greatly interfere with the cultivation of the ground, and in the course of a few years vegetables cannot be profitably grown under or very near to them; whereas low or small fruits succeed admirably planted as an undergrowth to the roots. The ground, being broken up to a good depth, or bastard trenched where the subsoil favours this proceeding, and in fairly good order as far as fertility is concerned, will support the trees and bushes for several years without manorial dressings being applied, while in after years a good surface of solid manure forked in or otherwise during every second or third winter will be all that is further needed. Digging among or about fruit-trees and bushes is most injurious to them, as it inevitably destroys very many of the best or most fibrous roots. Vegetable culture simply drives the roots of fruit-trees down into the soil, and in many cases very poor subsoil, the usual result of this injurious deep root-action being first a strong unfruitful top-growth, and then a gradual decline in vigour till they become stunted, the crops being of poor quality accordingly. Now if

THE TREES AND BUSHES are all grouped together, preferably in one quarter, or else alongside the walks, there is a greater likelihood of these receiving fair play, the vegetables also thriving far better when they get the full benefit of deeply, well-cultivated ground and are not unduly shaded down by the roots of the scrubby bushes, and Strawberries too old ap-

poverty-stricken to produce fruit worthy of being protected from birds prevail in far too many gardens, and more often than not are most apparent where there is no system of arrangement. In these days of cheap vegetables and fruit these must be well grown, or they will not pay for the labour and room expended on them, and I would, therefore, strongly advise the owners, or those in charge of badly-arranged gardens, to take steps at once towards rectifying the blunders that have previously been made. Large bushes of Currants and Gooseberries can be moved readily and without the loss of a crop, always provided an ordinary amount of pains is taken in lifting them so as to preserve a good-sized ball of soil and roots. Old

Glasses in place of bottles for keeping Grapes.

Raspberries do not transplant so well, and the better plan in this case is to form a fresh plantation of these, preserving the old stock till such time as the young canes are strong. Cherries that have not been partially or wholly lifted during the past ten years cannot be moved so easily or safely, but younger trees or any that have been cut round with a view to causing the formation of a thicket of root fibres not more than 3 feet from the stem—a distance of 2 feet being preferable—can be shifted with ease and safety. Aucubas, however, ought not to run any great risks with what good trees they may be the fortunate possessors of, but there is nothing to prevent many of them from making quite a fresh start, more especially with young trees not interfering with the best of those they already have till such time as the new trees are producing freely. Evidently the cost of trees and bushes has no deterrent effect on many owners of small gardens, though they seem to prefer to buy a few every winter and to dump these in promiscuously. Better, far better, that a good, well-selected stock be purchased and properly planted when the garden is first taken possession of, compensation for this judicious outlay commencing during the second summer after planting, and gradually improving till at the end of about ten years, when all would most probably be at or near their best. Even when the trees and bushes are grouped together at one end of a garden mistakes can be, and not infrequently are made, in arranging them too thickly. If

TOO MANY STANDARD OR HALF-STANDARD TREES are planted, the chances are these will soon overgrow and render of little value the bushes among them. What may be termed the orthodox distance for planting standards is 25 feet apart each way, White, Red, and Black Currants and Gooseberry-bushes being arranged 5 feet apart each way all over the intervening spaces. If the standards are valued more than the undergrowth, and there is no mistake about their productiveness during an average season, it may be thought desirable to have rather more of these and fewer bushes. In this case the standards may be planted more thickly if due regard is paid to the habit of the kinds and varieties, those of strong growing, spreading habit alternating with those either less vigorous or of more erect growth. Plums are admirably adapted for alternating with Apples, Pears also as a rule requiring less space than Apples. If Apples alone are planted, then ought such spreading varieties as Early Julien, Duchess of Oldenberg, Warner's King, Blenheim Orange, Brandy's Seedling, Golden Noble, Claygate Pearmain, and the King of the Pyramids, Nonpareil, Cox's Orange Pippin, Wellington, and Winter Queen,

ing to alternate with the more erect-growing Echlinville, Worcester Pearmain, Keswick Codlin, Manks' Codlin, King of the Pippins, Bannman's Reinette, and Pott's Seckling. Under these circumstances, and the ground not being very rich, the standards may be put out 18 feet apart each way and two bushes disposed between them in the lines, and two rows in the spaces between the latter; or if preferred, the standards may be arranged 21 feet apart, pyramids and bushes of

APPLES, PEARS, AND PLUMS, the two former on dwarfing stocks, being planted 12 feet apart midway between and singly in the lines of standards, Currants and Gooseberry-bushes being also planted singly between the rows of trees and 6 feet apart in a line midway between the latter. When first put out the ground will be thinly covered in either case, and there is nothing to prevent either vegetables or Strawberries being grown among the trees and bushes for two or three seasons at any rate, bulbous-rooted flowers, notably Narcissi, Daffodils, and Anemones, also succeeding well for many years, or enough to bear well. Apples, Pears, Plums as long as desirable. If pyramids and bushes are planted alongside garden walks, room can usually be found for Gooseberries in the angles between the trees, Strawberries also succeeding fairly well as a front row. Either single groups of Raspberry-canes may take the place of some of the bushes or they may be planted 15 inches apart in rows in the place of Gooseberries or Currants.

H.

STARTING FORCED STRAWBERRIES.

IT IS WELL KNOWN the slower the plants are forced the greater the certainty of success, so that those who require fruit early in the season would do well to give ample time and force in suitable temperatures. I lately saw it stated that ripe fruits had been secured by the end of December. It would be interesting to know the proportion of fruit to each plant and the quantity of plants forced. Another point worth knowing is whether from last summer's runners or old plants. I fear whatever system may have been adopted no large quantity of fruit would be obtained unless the plants had received a thorough rest. The best results in Strawberry forcing are really secured from plants started early in the air and given plenty of time with abundance of air. The best fruits I ever grew were from plants started on shelves in an orchard-house close to the glass without bottom-heat of any kind, and not removed till the fruit was colouring. This could not be termed early forcing, and one is not obliged to resort to speedier methods to get early fruits. To do this, excess of heat often destroys a good prospect of a crop, so that the longer the growing or forcing season the greater the success. Many excellent cultivators do not use bottom-heat at all, but in such cases to get early fruits early runners are imperative, also well ripened plants. These latter are placed in their forcing quarters early in December close to the glass with a free circulation of air, and in such positions, provided a low temperature is maintained at the start, say 45 degs. to 55 degs., with a rise of 12 degs. by sunlight, the minimum temperature in severe weather, and 45 degs. to 50 degs. at night, with ample supplies of misture, there will be fewer failures and less trouble with insect pests than if a higher temperature were maintained. Those who have a hothouse or orchard-house ready to start may find room for a few early Strawberries. I would advise a thorough cleansing previous to their introduction, as Strawberries are most troublesome in fruit-houses when not thoroughly prepared. If in a dirty state I find nothing better than a little sulphur mixed in water, dipping every plant before placing on the shelves; dry sulphur is also useful when dusted over the foliage. This checks mildew, but does not reach spider, so that it is best given in a liquid form. When introduced thus early

LITTLE WATER IS NECESSARY, as the roots will be in a moist condition. Dryness at the root is the commencement of the grower's troubles, bringing all kinds of insect pests. I also consider the old method of top-dressing the roots of little importance, and here I may be called to back, but I think it a waste of time, a destruction of roots, and a certain means of preventing the proper amount of moisture

reaching the roots. When a certain quantity of fresh material is added to the surface without any roots to absorb the moisture this remains in a damper condition than the ball of earth lower down. In these days, when there is a wide choice of fertilisers that can be used at the time the plants require assistance, this removal of soil (often roots) is not necessary. I would rather advise leaving more space on the surface at potting-time, so as to mulch with rich soil and manure when the flower-spikes are pushing up. When bottom-heat is used it should always be carefully applied; indeed, in some cases, if proper convenience cannot be afforded, I would prefer to stanch the plants on the bed to plunging them. When leaves are used, some fibre or old leaf-mould may advantageously be used for plunging; if stable-litter is the heating agency more care is required. Much good may be done by using thin boards or racks in case of high temperature, and by this means save the plants; 10 degs. to 15 degs. higher temperature at the roots over the day temperature is ample. When selecting the plants for early fruits, let it be remembered that the largest kinds are not always the best fruiters, especially for early work. So far I have found none better than Vicomtesse Héricart de Thury, La Grosse Sucrée, and Keens' Seedling. Early thinning of the limbs is also essential, as this hastens the formation of the fruit left. In fine weather a free use of the syringe will keep down spider and greatly benefit the plants. When mildew is noticed maintain a drier atmosphere and cover the pipes with sulphur, doing the work in dull weather. Liquid-manure should be used freely after setting. I like cow and sheep-manure in a liquid state, or a good fertiliser sprinkled on the surface. G.

FRUIT-TREES ON VACANT WALL SPACES.

The annexed illustration will, I think, give a good general idea of what may be done to render

5280.—**Fruit-tree trained on a wall.**—Holes made in the wall by nails do in the course of time harbour insects, so also do old shreds, and it would be better and neater to repair the wall and have it wired. For Peaches and stone fruits generally, I should prefer the wires strained diagonally up and down the wall so as to form diamonds about 8 inches in diameter. This facilitates the training of the trees, and will not be much more expensive. The wires can be fixed to galvanised nails driven into the wall.—K. H.

—Undoubtedly the best plan is to have the walls wired; not only can the trees be more quickly fastened than when nailing is practised, but the wall is not injured in the slightest. The chief point in wiring walls is to avoid having too great a space between the wall and wires in consequence of causing a draught, and thus rendering the trees less successful. Half an inch space is sufficient, or just enough to admit of the material employed in securing the trees to the wires to be passed around the wires. Galvanised driving-nails an inch long answer very well to support the wire, if driven into the wall 4 feet apart, with a stouter one at each end to make fast the wire. If the wires are strained along the joint between every other row of bricks that will be near enough.—S. P.

—It is supposed that the holes made by wall-nails harbour insects; but when we come to look carefully into it, and compare trees trained to walls that are well studded with holes, against those trained to wires, I have not found that there is so much difference—in fact, there is none. The aphid trile and red-spider are the only dreaded parasites which attack fruit-trees, and neither of them lodge in holes made in the walls. The disadvantages of wires over these: The shoots being trained to the wire, they are fixed at a certain distance from the wall, and a draught of cold air circulates between the shoots and the wall, which will certainly retard the ripening of the fruit, and may also cause the blossoms to be injured by frosts

to be galvanised wires, or if galvanised they should also be painted.—J. D. E.

—Yes; the wiring system is far superior to that of nailing the growth to the wall in the ordinary way. For the subjects mentioned the wires should be fixed about 8 inches apart, and 2 inches or 3 inches from the wall. Always cross the ties between the shoot and the wire, or else wrap a bit of cloth round the latter before tying the shoot to it.—B. C. R.

The Vine weevil.—The black Vine weevil (*Otiorrhynchus sulcatus*) is a most tiresome pest. As regards destroying the grubs, no insecticides are of any use; those which would kill the grubs would be equally deadly to the plants. The Vines should be repotted and a careful search made for the grubs; they are probably not more than 4 inches or 5 inches from the surface, so that searching down to that depth would be sufficient. The grubs will become chrysalides in the early spring, and the beetles will emerge a few weeks afterwards. The weevils only feed at night, hiding under stones, little lumps of earth, or wherever they can shelter themselves from observation. They may be trapped by laying pieces of slate, board, or little balls of hay about the soil in the pots, or in hay tied round the stems, or they may be caught at night by previously laying white sheets under the plants, and then suddenly introducing a bright light, which will cause them to fall; if it does not, shake the Vines well over the sheets, secure the weevils before they can get away (they do not move very quickly), and put them into boiling water.—G. S. S.

FERNS.

5275.—**Treatment of Ferns.**—Dead fronds may always be cut off Ferns at any time; but it is not generally wise to cut away all the green fronds when repotting. Maiden-hair Ferns are often cut down just previous, say a fortnight or so. This starts the new growth just a little, and on the least movement the plants may be shaken out and divided. By the term shaken out it is not intended that every particle of soil is shaken away, as this implies too great a reduction of the roots. When the plants are broken up so very small they are often a long time getting established again, and require extra care, especially as regards watering, and a little extra warmth is desirable. Newly-potted subjects should not be overwatered at first, or the soil may get sour before the roots are in a condition to enter it.—E. H.

—A good grower of Ferns would not treat them quite as "A. K. W." has done. First, as regards cutting off the fronds, please, not "leaves." If they are green and healthy they must not be cut off. Dead or decaying fronds should be removed. If a number of small plants are required instead of large specimens, it is easy to divide them, but better not to do it by cutting. The best way is to thrust the tines of a digging fork into the centre of the plant to be divided, and tear the plant in two. An iron implement invented by Mr. G. F. Wilson, and termed the "Wilson Digger," is the very thing to divide large plants. Two or more plants may be obtained from one. Repot carefully, but do not be too free with water at first. Fibrous peat is better than leaf-mould to mix with yellow loam for potting Ferns. All the soil should need not be shaken away; remove a portion with the broken and bruised roots.—J. D. E.

—Your treatment appears to be quite correct, but in cutting off all the leaves there is no need to disturb the little embryo fronds, so to say. The cutting away of dead fronds requires to be done with great care. I suppose you have hitherto had success with your Ferns, as you do not ask for advice on any particular point. After repotting stand the Ferns in the warmest corner of the house, and if the time of repotting occurs in the spring, shade them from bright bursts of sunlight. Very careful watering is required until they get established, and then more ample supplies may be given. Unless the Ferns are watered judiciously they never root properly. This remark applies to all newly-potted things in general. By saying the Ferns form into a hard mass, I suppose you refer to Adiantums and such like, which may be readily dissected, or the roots carefully reduced, and the same pots, after a thorough cleansing, again used.

Fruit-trees on the wall of an outbuilding

the vacant spaces between windows, &c., in stables and other outbuildings profitable and ornamental. In most cases the system of upright training here shown should be adapted, and many of the finer kinds of Plums, Pears, and Apples, &c., could be so grown to perfection and help considerably in the way of produce whether for sale or home consumption.

in the spring. There is also danger, when the shoots are tied to wires, of some of them being injured by the ties cutting into the wood, and causing gumming or canker. I have had to do with both, and have after many years' experience decided that nailing the trees to the walls is to be preferred to training the shoots to wires. I may add that if wires are used they ought not

HOUSE & WINDOW GARDENING.

WATERING PLANTS IN ROOMS.

"PLEASE come and look at my plant and tell me how often I must water it?" The above were almost the first words addressed to me when making a visit some few days ago, and I am afraid my answer gave the questioner a very poor opinion of my floricultural knowledge. I simply replied: "I am sure I do not know;" nor did I. Regularity and system are very valuable in many instances, but not among plant life, and least of all when applying water. For example, let us say we water a plant every day. What is the natural result? Sometimes it is sudden, and at others receives hardly sufficient moisture. There are stages in the existence of all plants when they need double and treble the quantity of water that they do at others. Independent of this, let us consider how very changeable the atmosphere is, and what a vast effect this must have in itself. A room has perhaps not had a fire in it for some two or three days, or it may be weeks. During this period the plant has felt need of little water; but when a fire is lighted and the atmosphere dried up, moisture from the plant naturally evaporates more freely, and in consequence the supply must be increased. Again, a plant is in a window; while closed there is not much water needed to keep the soil fairly moist; but if we open the window a short time we shall be astonished how dry the soil becomes, more or less according to the draught occasioned and the state of the air. Then a plant, say of *Arum Lily* or other water-loving subject, wants much more than a *Zonal Pelargonium*, and this is even more marked when growing freely or otherwise. If we except bog-plants, there are none growing in a state of nature which are kept in the same state of uniform moisture as many endeavour to secure when cultivating them in rooms. Nor do they receive regular supplies of water in given quantities. It is surely want of a little thought and consideration which causes persons to ask similar questions to that I have commenced with. As a general rule, all plants need twice as much water when growing to what they do while in a dormant or partially dormant condition. Some require to be kept perfectly dry for a short time, and then be supplied with large quantities. No amount of system will ensure uniform moisture under the varying degrees of temperature and atmospheric conditions our rooms are subject to; therefore, the only plan is to use a little of what my country friends call "gamption." P. U.

FERNS IN GLASS CASES.

IN reply to "J. R. T. Z." and others, yes; *Todea superba* is not only the most beautiful of the *Todeas*, but one of the most elegant of all cultivated plants. This and other allied species owe their ability to thrive in rooms where the atmospheric conditions are not suited to plant-life to their need of always being kept closely confined under a glass covering of some kind, either an ordinary bell-glass or a tight-fitting Fern-case, a still, damp atmosphere continually in contact with their delicate leaves being a necessity of their existence. Another merit they present is that they will succeed better in a room which has its windows facing the north than if they were in an opposite direction under the influence of the sun. In fact, these *Todeas* may be said to be completely useless in their wants, only requiring a subdued and limited amount of light; beyond this they will bear without injury a temperature so low that would be fatal to most plants usually grown in pots. Several degrees of frost will do them no harm. I remember once seeing a plant of this *Todea* which was placed in a room such as I have mentioned facing northwards. The pot in which it was growing was plunged in Moss in a large pan, and covered with a corresponding sized bell-glass; its largest fronds were then about 1 foot long. During the summer it made about a score more fronds, many of which were over 18 inches in length. The plant took a handsome vase-like form, the fronds from their base for some length upwards assuming a partially erect position, and then arching over with their points down to the Moss in which it was plunged. This plant gradu-

ally grew stronger and larger, until it became a very fine specimen. All the attention it received was to water the roots freely about every week or ten days whilst growth was in progress, but the top of the plant was never wetted in the least. The syringing or sprinkling overhead which this *Todea* is often subjected to is generally most injurious, causing the fronds to become brown, very different in its effects to the moisture that arises within the glass and covers them with a complete garniture of condensed pearl-like globules. During the winter months it does not require water oftener than every three weeks or so. To those who

The Killarney Fern (*Trichomanes radicans*) under a glass case.

can see beauty in a plant without flowers, it is not possible to have a more charming object in a room. It thrives better where there is not a fire regularly, and does not require any artificial heat, unless there is more than 8 degs. or 10 degs. of frost, which is not likely to occur in many houses.

THE KILLARNEY FERNS (here figured), which is one of the most beautiful of Ferns for glass cases, loves a moist, confined atmosphere. In order to grow it successfully in a room, it should be enclosed in a case, which, when closed, effectually guards it against the draughts and the parched, vitiated atmosphere which often prevails in such a situation. The case may be made of any desired form or dimensions, but it is imperative that provision be made for thorough drainage, one way of effecting which is to form a false bottom, made of punctured galvanised iron. The lower portion of the case should be so constructed that it may be drawn out at will, thus affording means for emptying away any superfluous moisture which may have drained into it. The soil should consist of fibrous peat in lumps, with which should be mixed some pieces of sandstone and a little coarse silver sand. In planting, use the soil in a moist state, and water no more than is necessary to preserve it in a moist condition. In hot weather a gentle dowing overhead will be beneficial; but from September to May syringing must be discontinued, and water at the root must then be cautiously administered. B.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

THE earliest batch of cuttings put in for the purpose of producing large high-class blooms the early part of last month will now be forming roots. The recent spell of wintry weather would be the means of checking their progress, if the cuttings were not absolutely safe from its effects. Even then some care is necessary in affording sufficient ventilation to prevent the leaves from damping during dull and sunless weather. After a frost leaves or cuttings in a confined space are more liable to be affected by damp than at any other time, owing to the larger amount of condensation of moisture that is prevalent. If the cuttings occupy a small frame or hand-light on the stage in the greenhouse or other cool structure, remove the lights regularly for at least an hour every morning to dissipate the condensed moisture that collects on the glass and around the sides of the inside of the frame during the night. It is a good plan to wipe the glass inside the frame every

evening, keeping a sponge handy for the purpose. Such a precaution minimises the amount of moisture in the morning. If any of the leaves exhibit signs of decay remove the parts affected, as this will prevent, to a great extent, the decay of the whole leaf. During the time the cuttings are forming roots but little water will be required. The soil should be maintained in a moist state and no more. It is a mistake, however, to allow the leaves to flag for want of water, as this hinders root formation. Directly roots are formed a little air should then be admitted by tilting the lights slightly at first, and increasingly until they can be removed altogether; but while some of the plants need air the leaves of others will flag. This is caused by those particular varieties not rooting quickly and strongly. These should be removed to a frame by themselves, where they can be kept closer than those which do not flag and require more air to retain that stocky growth which is such an advantage. When the plants are well rooted, and will bear free exposure to the air without flagging, remove them from the hand-lights and place them upon a shelf close to the glass in the same house where they were struck. The temperature should not rise higher than 45 degs. by night, and not more than 55 degs. during the day, admitting abundance of air to maintain a stocky growth. The advantage of a light position is that it prevents their being "drawn up" weakly. If *Chrysanthemums* are placed in a rather warm temperature, and some distance from the glass also, it is surprising how quickly the growth is weakened. It is so important in good culture that a stocky foundation is laid, without this success cannot follow. If the house is not provided with shelves temporary ones can easily be put up by suspending them from the rafters by means of strong wire and screws. The shelves may be about 9 inches wide, according to circumstances, and on each side there should be a groove to run the water off to one end, which can easily be done by allowing a slight slope in fixing the shelves. Any plants standing underneath the *Chrysanthemums* are then not splashed by the water given the plants overhead. E. M.

Summer Chrysanthemums.—There is so much heard about the Japanese and Chinese *Chrysanthemums* in the autumn and winter that we are apt to forget how much we owe to various other members of the family at other periods of the year. The frutescens forms, after all, are, in a general decorative aspect and especially for market purposes, perhaps of much more importance than are any other varieties of species, for they bloom under judicious treatment for fully eight months, will make first class pot plants at any time, are employed in vast quantities for domestic or window decoration, for greenhouses, and for bedding purposes. They can be propagated from cuttings as easily as any greenhouse or bedding plant we have, and the flowers are of the most beautiful kind for ordinary uses when cut. This frutescens *Chrysanthemum* does not lend itself to the winning of prizes at shows; hence we hear so little about it. Of hardy annuals, there are the golden-flowered single forms of *scotum*, the double white and yellow varieties of *coronarum*, all wonderfully profuse bloomers; the singularly varied and beautiful forms of *tricolor*, some of which may be said to present the prettiest of single or Daisy-like flowers in cultivation. All these we can have from seed with the greatest facility and in bloom for fully five months if sown for succession. Then the giant *Daisies* are also *Chrysanthemums*, and *leucanthemum*, *maximum*, *laeustum*, and the tall *uliginosum* give of perennial forms a wealth of beautiful flowers from June till the end of October. Still, of all these forms little is heard, little of fuss is made; they give rise, happily, to no wrangling, and are in no danger of being strangled by the cruel love of the rule-of-thumb florist.—A.

Sweet Peas.—Quite safe from the attacks of both mice and birds are Sweet Peas when sown thinly in 4½-inch pots and stood in a greenhouse or frame. Perhaps in gardens where there is much to do every little labour of this description renders doing it well difficult until the sowing of 100 4½-inch pots with

soil, sowing in each one several seeds, adding a little more soil, watering freely and standing the pots on the floor of a temperate house or in a gently heated frame does not take long, and once done there can be no doubt whatever but that great advantage is gained. If it be desired to have extra early flowers some of these pot clumps of Sweet Peas may be shifted later into 9-inch pots, and in these be early bloomed. If wanted for the formation of clumps in the borders, they can be turned out about the middle of April, when the plants are 6 inches in height, and thus having ample room and well staked will produce clusters of growth and flowers of the most desirable kind. If, on the other hand, wanted to form a long row or line, the clumps turned out from the pots may be divided into two, then be planted in a shallow trench at 9 inches apart, and in that way will soon develop into a beautiful hedge of flowers and foliage. A sowing made in the open ground just at the time these are planted out will give a capital succession for late summer and autumn flowering, and will then be less likely to suffer from the deprecations of mice or birds. When sowing the more recently introduced varieties it is decidedly the wisest course to sow the seeds in pots. There is sometimes danger from mice even in houses and frames, but in such cases the pests can be overcome by persevering with the usual remedies.—D.

OUTDOOR PLANTS.

5260.—**Best Carnations.**—There are very few Carnations that do not burst their flower-pods at times, especially when grown in unfavourable positions as to soil, and during bad seasons. I have had to discard a good many from my collection on account of this failing, among others that well-known old favourite (fleur de Nancy, which, planted in the open in the calcareous soil here, failed some years to produce any flowers that were fit to use without the aid of matting or wire. The list of varieties in GARDENING (December 27th, p. 595) have been selected either on account of their colour, or because I have found them less liable to this unfortunate failing, and are probably the least liable of the several colours to this defect. Probably we shall have, in the not far distant future, plenty of border Carnations which will not only grow in any good garden soil without pod-bursting, but will also bear very fragrant flowers, and among these will most probably be found some improvements on such good varieties which we already possess, as the Old Glove, Blush Glove, or Satin Queen, W. P. Milner, the Governor, the Duke, Ruby Castle, Ketton Rose, Rose Celestial, Comte de Chambord, Gorinaia, though this seldom bursts with me—a friend who treats his Carnations very liberally complains that 50 per cent. of his flowers of the variety, Mrs. R. Hole, are spoilt through bursting. Although to some extent a burster, this is a variety we cannot well do without, on account of its unique colour, especially for supplying cut flowers. There are, I believe, varieties in existence which are supposed to be a long way ahead of this variety, but till they become better known, and are to be had at popular prices, Mrs. R. Hole will take a lot of beating.—F. B., Winchester.

5272.—**Ipomœa pandurata.**—This is a deciduous hardy climbing plant from North America, which, as far as I know, no one in this country has ever succeeded in getting it to flower. I remember some years ago that several people tried it, but failed to get any satisfaction out of it. The hardy Hibiscus you mention I do not know; but if it is of the same character as those grown in England, I may tell you that it is more likely to succeed in a peaty soil than any other.—J. C. C.

5255.—**Auriculas in a garden.**—If the weather permits a good top-dressing would probably be the best treatment for your Auriculas. A mixture of two-thirds good fibrous loam and one of leaf-mould and well-decayed manure, with a good handful of soot added, would be preferred, or, failing this, some good garden soil could be used. In this they would root freely from their stems, and

would greatly facilitate replanting after flowering, as you will then know which varieties are worth troubling about.—F. B., Winchester.

A note on Christmas Roses.—It is only in soil of a suitable character that it is safe to lift these plants every two years and then divide them afterwards. Anyone with a soil that is naturally heavy, cold, and unsuitable to the quick growth of these plants will find a difficulty in managing them in this way, unless a large stock of plants is available, so I adopted the plan of making a plantation of the best roots on an east border of a size suitable for covering with an ordinary two-light frame. I took out the subsoil to a depth of 18 inches, retaining that on the surface, while the bottom was thoroughly broken up to allow of the water running away. Loam, peat, and leaf-soil were added in about equal portions. The clumps were planted in the spring after flowering, and now they give a wealth of bloom every year at Christmas, with but a tithe of the trouble experienced in lifting and dividing the roots afterwards. When the last flowers are cut from the plants in February, or sometimes it may be in March, the frame is taken away, if the weather is at all suitable. The old flower-stems not used when fresh are cut away, and a mulching of horse-manure is given to the plants. When growing, abundance of water is given if the weather be hot and dry, and occasional doses of liquid-manure are supplied, inducing good growth, which is all in favour of a full crop of flowers the next year. It is surprising how soon Hellebores suffer from drought. The lights are put on in the middle of October, abundance of air being admitted at all times, except in the case of cold weather, when the flowers are pushing up and it is thought they will not be expanded by any particular date.—E.

NEW ZEALAND REED (ARUNDO CONSIGUA).

This is a capital companion for the Pampas Grass, especially in the western counties of England, and on good soils. In some very fine deep soils it reaches a height of nearly 12 feet, and it is well worth growing where its dimen-

New Zealand Reed (Arundo donax).

sions are much less. It flowers before the Pampas Grass, and is a fore-runner of that magnificent plant. It makes a noble specimen for the lawn, where it grows well. It commences blooming in July, lasting until the end of October. Grown in tubs in a cool greenhouse or winter garden this noble Reed is very handsome, and its silky plumes (see illustration) last in perfection much longer than in the open air. It likes strong, fibrous, loamy soil, and plenty of water nearly all the year round. It is propagated by seeds or division. It requires careful planting, and generally several years' growth after transplanting before flowering.

ROSES.

MARECHAL NIEL ROSE.

No doubt this will always be more or less erratic in its behaviour out-of-doors. A few other Roses are somewhat so, but none to the extent that characterises Marechal Niel. Good free-growing, constant-blooming plants may occasionally be met with, but generally its behaviour is indifferent, and it does not always readily respond to our endeavours to induce healthy, vigorous growth. Although I have not actually proved the value of the cutting-down plan in the open air after flowering, I have tried an experiment in this way, and which perhaps was likely to lead to good results. It seemed so in my calculations, but I failed to realise expectations. In my case six dwarf plants on the seedling Brier-stock were planted in a very favourable position against a warm wall with a south aspect. They were rather close together, and as all made a vigorous growth, there was not room to train all the shoots properly. The idea then occurred to me that perhaps by laying in almost full length the shoots of three plants and cutting the others down to near the ground I might have them in succession, assuming that the cut-back plants would, as the result of their hard pruning, make a vigorous growth to lay in for flowering the following spring. Those that were unpruned flowered well and finely, but the cut-backs only make a weak, puny growth, and therefore quite defeated my object. A variety of circumstances has to be reckoned with out-of-doors that do not interfere with or influence culture under glass. With so many really reliable first-rate Roses it seems almost a waste of time and space to attempt the growth of Marechal Niel at all extensively. I have had no experience as to whether it is long-lived as a standard, but it certainly grows very well in this way. A number of standard and half-standard plants that I have seen in Mr. Frank Cant's nursery on several occasions always surprised me with their health and vigour, and they reward him with hundreds of perfect flowers. Nothing like hard pruning is resorted to in spring, but the long strong shoots are brought down more or less horizontally and tied to stakes. So treated they flower almost their entire length. A.

FORCING ROSES.

In the early forcing of Roses, endeavour to maintain a temperature of 45 degs. to 50 degs., then all will be well; but do not be alarmed if, with the appearance of the sun for a few moments, the temperature rises to 55 degs. or even more. This will be of benefit to the plants, but on no account admit air. If the sun be more than usually strong at this season the fire may be steepled for awhile, but be careful this is not too long-continued, as the water cools quickly in such weather, and the temperature of the house will rapidly decline when the sun has again disappeared. One very important item in the forcing of Roses early is obtaining the fullest amount of light, and to ensure this, the glass will have to be washed occasionally to clear off the soot which remains after a dense black fog. Nothing short of hard rubbing will remove this greasy black deposit, which so effectually excludes the light, and nothing is better suited for the purpose than the brushes obtainable from any horticultural tradesman. These affixed to a handle simplify the washing of glass roofs, having a lad with a coarse syringe to damp the glass in advance, and to return at intervals to rinse off what has been washed. During severe frosts it is impossible to do this, as the water freezes too quickly; but advantage should be taken of the earliest opportunity, as the plants suffer considerably when light is thus obscured. Fumigation must be done in advance, as it were, to keep insects in check. Once they get the upper hand it is almost impossible to eradicate them without injury to the plants as well. It will be found better, as a rule, to fumigate twice moderately rather than attempt the destruction of the pest at one strong application. A good preventive measure, and one by no means so much in vogue as its effectiveness and simplicity merit, is that of syringing with weak foot-water occasionally, making the solution several days before use.

Soot is especially valuable in the Carnation-house, and young plants I frequently water overhead with it, particularly if red spider exists. Such simple means as these are too frequently overlooked, and those who have not tried the above in the way now suggested should lose no time in doing so. As soon as the limbs are well formed and have emerged from the foliage, a little weak stimulant may be given, starting with soot-water first, and afterwards about twice weekly, giving some good artificial manure in a weak solution. It will be found advantageous to apply it in a weak state and frequently, rather than in stronger doses at longer intervals. It is also advisable to change the food supplies; when the limbs begin to show colour stimulants may be discontinued. E.

THE GROWTH OF TEA ROSES.

SOLS, situations, and local peculiarities determine a great deal, and in some degree account for the varied experiences of different Rose growers. Reading the remarks of another rosarian and comparing them with one's own experience frequently reveal some decided differences so great as to be almost unaccountable. Observations, however, of the different growth of self-same kinds upon heavy soil in the south and in lighter soil in the eastern counties lead me to suppose that we err in trying to grow all the kinds under uniform conditions, more especially as regards soil. Now that ardent growers, not of Roses alone, but of other plants as well, do so much towards preparing for them a site and soil as congenial as it is possible to be made, I think it is quite an open question whether a bed of lighter soil than that usually sought after and considered the essential for Rose growing might not be the remedy for so-called delicate kinds and the means of inducing greater vigour. There would certainly be increased ability to withstand low temperatures, because hardiness is very much proportionate to the capacity the soil has for retaining water—at least, such is my idea. There is, of course, nothing like uniformity as regards habit of growth, but there is a marked difference between the behaviour of *Niphetes* in various localities. In my previous notes I have alluded to the fact that, being so largely grown under glass, it came to be regarded as a dreadfully tender, if not absolutely worthless, kind for open air culture, and that this was very far from being the truth. In consequence of this pendulous disposition of the flowers, I made a group in walled border, and a very pretty one it became. The bushes grew strongly and flowered most freely. The second lot of flowers came finer than the first, and some of them were borne quite erect on strong shoots. I used to think they had much more substance than the comparatively flimsy blooms I have seen under glass, but, at any rate, especially towards autumn, in the milder days, the flowers were more lasting. The plants never showed any extra susceptibilities to cold, and they have endured the rigours of all the winters that have passed since they were planted entirely unprotected and without suffering. In a less favoured garden I have seen *Niphetes* at the foot of a wall growing vigorously and producing fine flowers. Mr. D. T. Fish used to praise *Niphetes* grown in this way, and I think the majority of rosarians will hardly go so far as to discard it for delicacy or poor growth. *Souvenir de Paul Neyron* has been mentioned by some as a tender, uncertain Rose, but I have always found it the very opposite of this, and, growing in its own way undisturbed, no kind could give a greater proportion of fine flowers than this has always done. My first experience of *Innocent Piroli* was in heavy soil, where it was most unhappy, but elsewhere it proved one of the very best Tea Roses, and the bushes grew quite a yard high. I am not sure of *Cleopatra*, but Ernest Metz last year proved that it possessed robustness. There is a danger of a fine Rose such as this being over-propagated at first, and it is a matter of two or three years before it reveals its true character. *Ethel Brownlow* is held in high estimation by the exhibitors, and I must confess to being astonished with some blooms I saw cut from standard plants in one of the large Rose nurseries last year. With me, growing as a dwarf, its shoots have always been of a thin, wiry character, and the flowers, though well formed, were small and of little time of life too pronounced.

SINGLE ROSES.

THESE ROSES make such beautiful additions to our rosaries that they ought to be far more generally cultivated than is found to be the case. For instance, they include some of the very best climbers—that is to say, climbers that are exceedingly hardy, immensely vigorous, but little subject to disease, and extremely free flowering. Such a one is *Rosa polyantha*, which will grow anywhere to any height almost, and hide itself in June under a snowy awning of white blossoms of delicious fragrance. It may be propagated from cuttings in the open ground more rapidly even than *Manetti*, and it is absolutely hardy. *Rosa Brunneava* (here figured), again, though scarcely so hardy, makes a most distinguished-looking climber, with its glaucous foliage and great trusses of white flowers. Then the North Americans, *Rosa lucida* and *Rosa nitida*, are always attractive for their glossy foliage and brown stems, even when they are not covered with bright, rasy flowers or brilliant scarlet bunches of hips, and they are as hardy and vigorous as possible. *Rosa mucronata* may be regarded as a queen among single Roses, with its great, royal-looking blossoms, flesh tinted, and crowned with a gleaming diadem of golden stamens; and *Hebe's Lip*—not a species, but generally classed as a hybrid Sweet Brier—with large flowers, having a purple margin to each white petal, is not less beautiful. There are

Flowers of *Rosa Brunneava*.

many delightful forms of the Sweet Brier, but most of them are either double or semi-double. The Austrian Briers, yellow and so-called (mis-called) copper, are, of course, amongst the most distinct and gorgeous of all Roses, single or otherwise, and a great mass of either seen at its best is a sight not readily to be forgotten. The Rugosas, white and red, are also very handsome, both in flower and in fruit, and well known, though they cannot on that account be omitted from a list of the best. A single Rose which is not often seen is one of the most fascinating things in the whole rosery; it is *Rosa berberidifolia* (Hardy), which throughout the summer produces a wealth of blossoms. The flowers have clear yellow petals, with a narrow blotch at the base of each, delighting everyone who sees it. A bush of well-grown flowers of this Rose is a never-failing attraction at a Rose show. Anyone who has a rockery—for which it is particularly well adapted—should grow this charming and hardy Rose. G.

3274.—**Making a propagator.**—I made my own propagator, and this is how I did it. I got a box 2 feet long, 16 inches wide, and 18 inches deep. I removed the top, and on one side removed the lower half of the boards and hung it on hinges, so as to get the lamp in and out, and to close it afterwards to shut in the warmth. I then secured a zinc tray 1 inch

deep, the size of the box inside. Strips of very narrow boards were then nailed on to the sides and ends of the box, and 9 inches from the bottom, on these strips, the tray rests. The tray is then filled half full of water, and on the top of it is placed a sheet of perforated zinc, and on the sheet of zinc I place half-an-inch of Cocoa-nut-fibre or sawdust all over. Three ordinary squares of glass are placed on the top, and, except the lamp, the propagator is complete. I use an ordinary petroleum-lamp with a glass, which together is 8 inches high, and the best petroleum obtainable. With this simple contrivance I can get a temperature of 95 degs., if I wanted so much.—J. C. C.

ORCHIDS.

SLIPPER ORCHIDS (CYPRIPEDIUMS).

"JESSE CHAPMAN" wishes to know if I will give him a description of about a dozen Slipper Orchids? Yes, I will; but he must understand that there are many dozens to choose from, and the kinds given may not be just the ones he wants; but they may be added to ever as he thinks proper. The plants all require to be well drained; those kinds which are noted as limestone kinds should have a compost of all limestone; but for the other kinds use pieces of broken pots. The soil for the majority of the kinds should consist of about equal parts of rough peat, chopped Sphagnum Moss, light-yellow turfy loam, and sharp sand; but the species which grow in limestone should be potted in that material, and be likewise drained with larger pieces of the same. The house should be kept nice and moist, and the plants be well supplied with water to the roots, keeping them in a temperature of the East India house, never allowing it to fall below about 65 degs. at night in the winter, rising to 70 degs.—80 degs. by sun heat in the summer. They should be kept warm enough in the winter to allow some moisture being used about them, so as to keep their foliage in a moist and healthy condition.

C. BEALATIUM.—A species introduced by Mr. Stuart Law some four or five years ago, and it is one of the most charming of its kind. The flowers are large and beautifully spotted, and its foliage is richly marked and large. But the plant has not been alone justine in, which arises in the first place, I think, from wrong potted, and no matter how friends laugh, I advise them being potted in broken limestone and fine yellow loam, besides putting the large pieces of limestone on the bottom of the pots as drainage. The dorsal sepal and petals are very large and round, and they are in colour from pale yellow to pure white, more or less spotted, and blotched with brownish-purple, tinged in some examples with a shade of rose; the lip is small, and is sparingly dotted with the same colour as the petals. It is nearly related to *C. Godefroyi*, but is much superior.

C. CONCOLOR.—This is a somewhat small-flowered plant, the blossoms having a yellow ground over which is spread some reddish-purple dots. It is a limestone plant, and has improved very much under this treatment.

C. CERNIS. is a large-flowered and very beautiful form; the flowers are large, the petals deflexed, with purple dots on a darker ground, dorsal sepal vivid green, with a broad white margin. Some very fine forms have appeared from an importation made of this kind by Mr. Smiler, of St. Albans. The flowers of these are not spotted like many of the section to which it belongs.

C. DIVERSI.—This is a plant found by Col. Drury on the Travancore Hills, quite isolated from other members of its race, and there many others are doubtless to be found. It appears to be somewhat of a sparse bloomer, the flowers being rich yellow, with a broad chocolate band down the centre of each segment.

C. NELLORIANUM is a strikingly beautiful plant with large flowers, which are produced four and five together at the same time, and which render it very beautiful. It was introduced by Mr. Sander. The flowers are large and spreading, the ground colour is white or creamy, thickly streaked with blackish lines. It appears to approach *C. Stonei*, but it is a much easier plant to cultivate, and more effective when in flower.

C. LAWRENCEANUM.—This is like a very gigantic form of C. barbatum, both as regards size and colour, and it should be in every collection. Its broad dorsal sepal is very conspicuous.

C. LOWI is an extremely handsome species, found growing upon lofty trees in the jungle in Borneo. The segments are greenish, having beautiful reflexed petals some 3 inches long, spatulate, the points being light, the lower part yellowish, spotted with black. It has several blossoms on the spike.

C. NIVEUM.—This is another of the limestone plants, producing pure white flowers, dotted with purple, which makes it a very desirable plant with the ladies. The dorsal sepal and the petals are pure white, saving the fine dots upon it.

C. STONEL.—A superb form, from which originated the only plant of the variety known as C. platyllum. It is a very distinct and pretty Slipper Orchid, having broad, white sepals, having a few lines of black. The petals are long, slightly reflexed, white near the base, becoming yellow towards the middle and upwards, spotted with black, the lip rose colour, streaked with crimson.

C. SPICERIANUM.—This is a very pretty and telling kind, more especially as it blooms in the late autumn months. It has a broad dorsal sepal, of the purest white, saving a broad centre streak of dark chocolate up the centre. The petals are green, beautifully frilled on the edges; lip also a soft green.

C. SUPERBIENS is one of the very best of the C. barbatum group. It is beautiful in the extreme; it has bright, fessellated leaves and large, light-coloured flowers; the dorsal sepal is broad white, streaked with vermilion. The petals are slightly flushed with white, much spotted with lines of blackish warts, and delicate at the edges; the lip of good size, brownish-purple.

C. VILLOSA.—This is a noble species, having very strong foliage, dark green on the upper side, paler beneath, freckled at the base with black. The flowers are large, and somewhat variable in colour, having a varnished appearance; the dorsal sepal brown from the centre, which is succeeded with a green tinge, the outer border white; the petals are broadly spatulate, having a central vein of brownish-purple, the upper half being of a rich chestnut-brown, the lower half paler in colour; lip large, tawny-yellow. There are numerous named varieties of this plant which I pass over to a more fitting occasion; but all of them with the typical plant require rather less heat than is given here for the dozen kinds asked for by "J. G."

MATT. BRAMBLE.

5278.—Wireworms in leaf-mould.

The wireworms must have come up out of the ground into the leaf-mould, and if it was spread out in the winter they would instinctively go out of the mould into the ground again to escape the frost. I believe if the leaf-mould was spread out on frozen ground, and a sharp frost set in to thoroughly freeze the leaf-mould, it would kill them. If it is required for a Potato-bed, I would mix it with good stable-mannure fresh from the stables; enough should be used to cause a good heat and steam. I kill all the wireworms in our turfy heap in this way. A few escape to the outside of the heap, but I turn it over again and that kills all of them—J. D. E.

5264.—Oil-stove.—If properly managed an oil-stove in a conservatory will not injure the plants; but very often such stoves are not properly managed. The lamp either gets dirty and smokes or something or other goes wrong. Some time ago I went into a conservatory warmed with an oil-stove, and everything in the house was black from the lamp smoking. The stove had been temporarily left in charge of a servant who did not understand its management, or else was careless about it, and the whole thing went wrong. The larger stoves should have a pan of water on the top, as this keeps the atmosphere genial.—E. H.

The danger of oil-stoves is when they are neglected, or the wicks get too high, creating an unpleasant suffocating smoke. When, however, the wicks are kept properly trimmed, and the stove attended to carefully in other respects, there is no risk. Many small greenhouses are heated through the winter months

with an oil-stove, the common form of heating apparatus for amateurs to use. A small stove will warm a comparatively large structure. It is gas that is so destructive to plant life, and a gas-stove in a conservatory is certain to produce undesirable results.—C. T.

—An oil-stove is not injurious to plants in a conservatory provided the flame is properly managed. If too high we get a choking smoke; when not high enough the oil ascending the wick is not consumed sufficiently fast, and we get its fumes in the atmosphere. Lamps of all kinds dry the air very much, and detract from its qualities; therefore it is better to follow the Russian plan and occasionally place a pan of water over the flame and avoid too parching a heat.—P. U.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the same issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions should mean very so implicitly that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5291.—Rosa rugosa on a lawn.—I have some Rosa rugosa planted in a lawn. Ought the turf to be removed over the roots?—P. F.

5292.—Grafting fruit-trees.—Will someone give me instructions how to graft Pear, Apple, and Plum-trees, and the proper period of the year to do the work?—BURY.

5293.—Parasitps for show.—Will anyone kindly tell me how to grow these for show, the best kind to grow for size, and when to sow the seed? Soil is of a retentive nature.—D. T.

5294.—Cow-manure.—I put a good layer of cow-manure on my Roses, trillies, and Rhododendrons. I am told that it will kill the Rhododendrons. Is that so?—W. D. E.

5295.—White Chrysanthemum.—Will "J. Green" or anyone else, kindly state if there is a White Chrysanthemum of the same type in cultivation equal or superior to Elaine?—T. N.

5296.—Lysimachia Nummularia aursa.—Will someone tell me if the above can be raised from seed; also the culture of same, and can the seed be purchased from any seedsman?—H. G. K.

5297.—Lihonia floribunda.—Will "P. J." kindly say if this plant will flower in a greenhouse without heat in winter, and is Lihonia pentstemonia the same plant or of the same kind?—LONDON.

5298.—A hanging-basket.—What would be the most effective way to adorn a hanging-basket, 15 inches in diameter, for a greenhouse? When and how should the work be begun?—A. E. W.

5299.—Table plants.—Will anyone inform me if there is a rule in exhibiting table plants as to the height of them, and if so where could I find it? I have been told there is a rule.—W. M.

5300.—Plants out-of-doors.—Would anyone kindly inform me if they have tried to grow the following, and with what result (out-of-doors); they are both hardy: Ipomoea pandurata and Child's New Hardy Hibiscus.—A. A.

5301.—Creeper for a window.—Would someone tell me a nice Creeper to hang over the sides of window-boxes? I have got a lot of boxes to fill for windows, and should be much obliged to anyone who would kindly tell me.—BENABOS.

5302.—Treatment of lawns.—I should be much obliged if anyone will tell me the best method of fertilizing lawns, killing Moss, &c., and whether wood-ashes are good, mixed with some phosphate, and if so in what quantities?—C. COLBERT, J. W. WAGNITT.

5303.—Winter Apples, &c.—1. What is the best way to keep dessert Apples in prime condition during the winter? 2. How long should Ribston Pippin, King of the Pippins, and Ribhish Oranges keep good if treated in the right way?—H. W.

5304.—Pine-apples.—I should be pleased if someone would give me the culture of Queen Pines, now in 9-inch pots and twelve months old, about August, and what degree of heat they should be in now, and should they be potted once more or not before they fruit?—W. M.

5305.—Japanese Chrysanthemum, &c.—Would "Mr. E. Molten" kindly give me a few hints on the culture of the Japanese, Anemone, and large-flowering Chrysanthemum, and when they should be struck, and the names of a dozen in each class?—W. M.

5306.—Treatment of Cannas.—Will someone kindly tell me how to treat Cannas raised from seed last year? I want to increase my stock of them. They are in pots in the greenhouse, and the leaves are still green. Ought they to be dried off?—H. T. O. H.

5307.—Asparagus tenuissimus, &c.—Will someone kindly tell me if Asparagus tenuissimus and Asparagus plumosus name will do well in a greenhouse without heat? I should also like to have the names of a few of the best family Ferns for such a house?—ARTURUS.

5308.—A Privet-hedge.—I have planted a Privet-hedge. The plants have two to four shoots on each one, and are 3 feet high. Will someone please to tell me if I must cut them down, and if so when is the best time to do it? I want a good thick hedge right from the bottom?—R. H. F.

5309.—Crickets in a greenhouse.—What can I do to destroy, or at least prevent, crickets from doing damage in a warm greenhouse? Last spring I was sorely troubled with them eating stuff off as it came up in seed boxes. With me Cherry seedlings seem to be their favourite attraction.—FRESHMAN.

5310.—Sowing seed of Calla, &c.—1. When should I sow seeds of Calla althimica? Will they flower next year? 2. When should I sow seeds of Grinstae? 3. When is best time to buy plants of Genistas and Hydrangeas? 4. When is the cheapest and best time to buy Calla plants?—AMATEUR.

5311.—Room plants nipped by frost.—Will anyone kindly say what is to be done with Hare-foot Ferns and Nile Lilies (Callas) which have been nipped by the frost, and are withered and drooping? Ferns the same. All this happened in a drawing-room, and are required in the night.—GREAT DEPARTMENT.

5312.—Lean-to house for a Grape-Vine, &c.—I am about to build a lean-to house over a Grape-Vine. Will someone kindly inform me whether a Lapageria, Oleanders, and Tea Roses in pots will grow in the same house? It will be 10 feet long 12 feet high by 7 feet wide, the situation facing south-east. It will be a cold house.—MAURICE MINNER.

5313.—A saddle boiler.—Can a saddle boiler, with 30 gallons of water in the pipes, be heated with gas and some other material, which I do not know the name of, and it is largely used in heating stoves, and gives a good heat? Could I obtain enough heat for two houses about 10 feet to 12 feet high and 3 feet wide and 18 feet long? Would gas cost more than coke, &c.?—GABRIEL.

5314.—Plants in a cold frame.—I have a lot of cuttings in "Abranthum," Chrysanthemums, and Ferns with other things in a cold frame, which appear to be getting very dry, but in consequence of the severe weather I have been afraid to water them. Will someone please say how long this may be put off, and in some cases should the pots be placed in water for a short time?—SOCIETY.

5315.—Best market Melon, &c.—Will anyone kindly tell me the name of the best market Melon, and one likely to succeed in the following house—low span-roofed—framed by a line running round three sides of it. Over this line, on a stage, I propose to grow Melons. This line will give bottom-heat and top-heat. The house gets no sun till nearly March. Which would pay best—Melons or Cucumbers?—MATHW.

5316.—Plants for a bed.—Will someone kindly give me a list of plants, and advise me how to proceed to plant a bed 50 feet long and 4 feet wide with herbaceous plants, as I want to make one next spring to supply the house with fresh cut flowers, if possible to buy a supply from May to the end of autumn? The soil is good, and the turf will be a sandy soil. I have now some Pentstemon, so do not need any more of these.—THANKFUL.

5317.—An old Pear-tree.—Will someone give me advice as to what can be done to improve an old Pear-tree, the Chaumontel? One of our this summer bore a very large quantity of fruit, but the Pears were such a small size we did not care about them. Some of the finest, however, I kept to ripen, and found them with a delicious flavour that we are anxious to be in a way to improve the tree. Ought the roots to be pruned?—CHARMOTT.

5318.—Vigorous Chrysanthemums, &c.—Would "E. M." kindly inform me which of the following Chrysanthemums are most vigorous and most suitable for growing for decoration: W. H. Lincoln, Arabach, Mrs. Jamieson, Leon Fracke, Atheric London, Lily Bats, Bonle d'Or, J. S. Dildara, Miss P. Darison, Virgil Mord, Noble de Hocher, Pres. Harrison, Edwin Molyneux, Mr. R. Brahm. Kindly state which are most suited for cutting down?—R. B.

5319.—Early and mid-season Chrysanthemum.—Will "Mr. Molyneux," or someone else, kindly give me the names of six good early kinds, six mid-season in November, and six late? It is very essential that they be dwarf growers, not more than 3 feet high naturally, and white, except, of course, predominate. If such dwarf-growing kinds are scarce some information how to grow ordinary kinds dwarf and covered with foliage to the pots will be much appreciated?—H. W.

5320.—Plants suitable for growing with Roses in an unheated house.—At page 673, of No. 71, "P. U." writes, in reference to flowers in an unheated house: "Where other subjects are grown they will, of course, be those which need somewhat the same treatment, seeing it would never do to cultivate any which could not stand a low degree of frost." Will he kindly say what plants he would recommend as coming under this category?—NEWHAMPTON.

5321.—A Strawberry crop.—Would someone kindly let me know about how much fruit a thousand plants of Strawberries ought to yield, and which would be the best sorts to grow for profit? I have been told that President and Dr. Hogg are the best, that I could grow on the piece of ground I have two thousand plants. As I shall have to make the beds in April I am told I ought not to let the plants fruit this summer. Is this so? What would be a fair price for the fruit?—A. FREEMAN.

5322.—Asphalting.—Will anyone who has had a good experience with asphaltting be kind enough to set me right with my difficulty? Two years ago I had a good deal done in winter, which got soft and kicked up in summer—in fact, even cold weather it did not set well. My method was to heat the asphalt, boil the tar, mixing all hot, with a little warm sand, and after laying down gave an extra coat of tar, besides well, and mixing in the mixing. I shall be much obliged if anyone can tell the reason of it acting as it does?—BURY.

5323.—Fumigating.—I shall be very glad to receive information of a safe and effectual way to fumigate with Tobacco paper in a greenhouse containing mixed collection of plants, including Ferns and Heliotropes, &c., which on various occasions have always been infected by the smokes. The way I have long before was to place hot cinders in a large flower-pot and the Tobacco paper on the top, never allowing it to blaze. Will saturating the paper in alum and water be safer for the plants, and effectual in destroying green and black fly?—**FARMER.**

5324.—Fixing hot-water pipes, &c.—I have a lean-to forcing-house against a south wall, 20 feet long, 8 feet wide, 1 foot high at back, and 2 feet 6 inches in front. I have an Ecluse boiler and 36 feet of 4-inch piping, which I purpose putting in. How far should I have the pipes from the front? I want the house strictly for Tomatoes, which would be planted in the border, and have no slugging. How close may the plants be to the pipes without being damaged by the heat? I should like one row between the pipes, and then I think I could have three rows at the back if the wall will admit; in all about forty plants. Would that do?—**H. C. M.**

5325.—Climbing Roses in pots.—I should be much obliged for advice on the following subject: I bought a week ago two climbing Roses in pots, 8 inches across, for my unheated greenhouse. The Marochal Niel I re-potted into a much larger sized pot, 18 inches across. The other Rose, a W. A. Richardson, I planted out in the west border of greenhouse. Both plants have three long shoots, the centre ones being about 4 feet long. Might I spruce them, and if so how much? When ought I to apply any mulching or top-dressing. They are both planted in garden soil, mixed with a large proportion of leaf-mould. Advice will be very greatly obliged.—**NAKERRATS.**

5326.—Making a flower garden.—I wish to turn into a flower garden, with lawns and tennis-court, nearly an acre of pasture. It is so infested with weeds that on my man's recommendation I am trenching it all over to the depth of 2 feet that he may plant it out February with Dais and Grass seeds that both crops may come up together. The ground in front of course is available as a garden till next autumn or perhaps later. Would anyone kindly tell me whether the method thus described is the best, and what quantities of Oat and Grass-seed would be required? If not the best method, what would be advisable? Soil light and rather poor, gravel subsoil, near Farnham, Surrey.—**A. C. J.**

5327.—Roses in pots.—I have about sixty Roses in pots, chiefly H. P.'s. After last year's flowering I put them outside, and kept them out until end of November. Finding the frost had not harmed them then, and that they were beginning to show signs of life, I gave them a good top-dressing with nice loamy soil, mixed with a small quantity of labour manure, and then placed them inside. The house is span-roofed; size 30 feet by 10 feet, by 9 feet, and I also grow bulbs in the same house—Hyacinths, Tulips, &c. Please say if I treat Roses aright, and will the same temperature suit bulbs and Roses alike? I have house heated with one of Coore's heating apparatus, which I find satisfactory.—**LANSBURRY.**

5328.—Forcing Roses for out bloom.—Thanks to "J. C. C." and "P. L." for their kind information. In reference to the Roses I should like to know how many Roses the varieties "P. U." names (December 30, 1893, page 185) each house will take planted out and if grown in pots? I like it if the plants will grow on the outside of a hot-bug system, and be cut down each season after flowering? I might say the houses are built in two blocks of three with 20 yards between the two blocks, 3 feet to eaves, side walls, no partition walls, so I can get a free circulation of air through the three houses. They are going to be heated with a 6-feet saddle-boiler with water bars, so I could put more pipes in houses if required.—**M. K.**

5329.—Plants for a small greenhouse.—I have a small lean in greenhouse, facing south-west, no means of heating, except that a window from a room in which a fire is kept daily opens into it. I am a beginner, and want to get the best plants to grow in it. I have a speciality fond of Carnations and Violets. Will someone oblige by letting me know if I can get them to flower in winter in pots, and if so give a few of the best kinds, and the names of a few other flowers for winter blooming, and the best time to plant? In this greenhouse there is a border of earth about 24 feet wide underneath the stage for pots, which is 4 feet from the earth. What would be suitable for planting there, as it looks ugly in its present state? Locally, Kirkwall, N.B.—**B. H.**

5330.—Vines fruiting in pots.—Will someone please give me advice on the following?—I have just purchased four vines, two for planting and two for fruiting in pots. The first two were planted outside, the roots to be brought through a hole in the wall. When will it be a suitable to put them inside? The hole in the wall is large enough to put them through at any time without injury, if an length of rod should I leave when shortening back? The house is 5 feet to eaves, and no side growths will be allowed below that point. The roots are about 10 feet or 12 feet long. The two for fruiting in pots are in 12-inch pots with the same length of root. Should the fruit in the same pots or be potted afresh? What length of root should be left on these? How many bunches on each rod, and when should they be taken into theinery, the temperature of which is at present uniform, 45 degs., maximum, 60 degs. The kinds are usual found in a wall-ouable. The varieties are Black Hamburgh and Foster's Seedling.—**A. TERNS, Bucks.**

5331.—Marechal Niel Rose.—According to "J. C." statement recently in GARDENING, the only profitable way to grow this Rose is to plant it out in a border. Perhaps this accounts for my not having any blossoms on mine. I bought it last spring in 6-inch pot. It had some buds on it in summer, but they turned yellow and fell about a gavel ash in to a 9-inch pot. It has three rods, each about 4 feet long, with some young growths 3 inches to 9 inches long on the upper part of it (some of the largest tips of these I have taken off and potted to strike). At the bottom of the plant on the stock the bark is peeling off, and the stem looks as if it is rusty. It is on the stage in the cold end of an all-glass-roofed house. I should like a Rhubarb forcing cover that will enter the stage and bring the rods through it, so that I would be able to wash the sides of house with water. I have placed north side of this out of house, but not south

side), or I could plant it in a conservatory; then it would have to run in a wall 13 feet before it got to the glass. High side of lean-to only heated to keep out frost. I have a corner of rock-work here where it could be planted. This house is north-east, and does not get much sun, as it is shaded with trees. Should I be likely to succeed?—**H. B.**

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5332.—Poor man's record of Orchid growing.—Very interesting article. I shall keep them to mark how you improve.—**M. B.**

5333.—Remedy for bug and thrips.—A. E. Should obtain some "Sift and Sieve" insecticide, and he will receive instructions with it.—**M. B.**

5334.—Orchids with greenhouse plants.—H. M. must write and tell me what greenhouse plants he grows before I can say anything to him about what Orchids he can manage.—**M. B.**

5335.—Plants in a hardy fernery (C. C.).—I advise you to get plants for a month or more. You say it is all right for planting, but you had better let the snow and frost get off the ground before you attempt it. Please ask your question again in a month's time.—**J. J.**

5336.—Ferns for profit (J. P. W. and others).—I do not know what to do about this matter. It seems to me rather overdone, and as others have everything to begin with, and have their houses and pipes in good working order, therefore, I advise you to leave it alone.—**J. J.**

5337.—Summer-flowering Oatleya labiata (J. Birmingham).—I do not know upon what authority your friend names Oatleya Warner as this plant, although Warner is very like the typical flower; the plant you called C. Gaskelliana, years ago was known as C. latifolia pallida, but was called the Summer-flowering labiata; but perhaps your friend was not well enough up in Orchids to know that?—**M. B.**

5338.—British Ferns for a cool-house (H. G.).—Evergreen kinds are the only ones which will stand you in any service during the winter months. For instance, the Hart's-tongue Fern (*Asplenium vulgare*), of which there are innumerable varieties, will form a splendid show, as also does the Black Maiden-hair (*Asplenium Adnigrum-nigrum*), commonly known in market as the French Fern, which is always acceptable. The Holly Fern (*Polypodium lonchitis*) is another very handsome species. Any other hardy kind that retains its foliage may be used with advantage.—**J. J.**

5339.—Orchids for a span-roofed house (J. J. C., Lyndhurst).—Angulolabium and Barkeri; Cymbicaria barthata and cristata; Cymbidium chinense; Masderalia Chinensis, Toverensis, Dalmi, Barranua, Houletham, Shillworthi, Vietchiana; Maxillaria grandiflora, and Sanderiana; thalictroglossum linum, crispum, Cernatense, cirrhosum, glaberrimum, Halli, Himevelianum, luteo-purpureum, maculatum, Pescatorei, Polyanthum, Roseum, Sanderianum, tricoloratum; Oculodan coloratum, crispum, hastatum, inermatum, uscaratum, ornithocorymbum, ligulatum, varicosum, and Sophronitis grandiflora. The above will make you a start.—**M. B.**

NAMES OF PLANTS AND FRUITS.

*Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR OF GARDENING ILLUSTRATED, 31, Southampton-street, Strand, W.C.

Names of plants.—**P. Hardy.**—Hegonia Rex var. apparently, but sent a pair specimen is difficult to name. **Miss Reid.**—Apparently a Selaginella or Club Moss, but specimen so minute as to be scarcely visible. **W. Williams.**—Narcissus Tazetta var. **K.**—Apparently Cryptoceria japonica, but specimen sent is a better specimen.—**M. G. B. Stafford.**—Schizanthus lincecumii. **A. Bellon.**—Please send in flower; impossible to name from a single crushed leaf. **J. S. D.**—A small form of Lælia purpurata. **S. K.**—Looks like a Linnæa, but shiver too much crushed to name. Send better specimen in a box.—**N. Pears.**—1, Aspidistra lurida variegata. 2, Carnot name. 3, The common Laurustinus.—**W. H. Arthur.**—Paris pretia alba-alba. 2, Adiantum Canaliculatum. 3, Paris arguta. Leaf cannot name. **J. B.**—Strob. Gerythium. **Basilica.** leaves all varieties of B. Rex. **J. Parnet.** **Polypoda.**—1, Cryptoceria japonica. 2, Toxica hancata probably. 3, Cupressus Lawsoniana. 4, Cupressus Lawsoniana viridis. 5, Biota orientalis. 6, Biota chinensis. **Lady Amateir.**—We cannot name from description. It may be Hymenocallis. Send in flower.—**Oditham Chase.**—We should like to see specimens again when in flower.—**T. Bant.**—Euphyllium truncatum.

Names of fruit.—**Box of Apples.** No name or address.—Winter Quince.—**Lee.**—Apple: King of the Pippins. Mr. Goodrich, Clare.—Apple: 1, Wellington; 2, Norfolk Seedling; 3, Seekonk Partridge; 4, Ribston Pippin; 5, Roundwood Magnum Bonum; 6, Five-crossed Pippin; 7 and 8, Not recognised; 9 and 12, King of the Pippins; 11, Wellington; 11, Bad specimen. Please do not send so many in future, and more than one specimen of each kind should be sent.—**T. Bant.**—Apple: Northern Greening. Pear: Josephine de Malines.—**Ruff.**—Apple: Mère de Ménage.—**Thos. Borerie.**—Pear: Baster Bourré.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender. **Havener.**—Apply to a chemist or oil-store keeper.—**William Gray.**—Apply to Mr. B. H. Ravencroft, 14 Bell Wood, near Crawley, Sussex, who is the raiser of the Tomato in question.—**A. V. Cheshire.**—Yes; apparently a fair wood loan, and it should do for potting purposes. **H. B. Borer.**—The leaves have been badly affected with the scale, and the plant has been killed. **W. C. B.**—Fumigate with Tobacco and then syringe the plants with soapy water.—**Disappointed.**—I should

at the roots, most likely.—**I. M.**—Probably the above is dirty. We cannot tell without seeing it.—**Lady A.**—"Greenhouse and Store Plants," by T. Baines, published by John Murray, London.—**L. G. Jersey.**—Apply to Mr. J. Groom, Scotland-avenue, Hampol, Hants.—**Charles Ingham.**—Apply to Mr. E. Molwyn, Swanmore Park Gardens, Bishop's Waltham, Hants.—**Mr. G. B. Southwell.**—Pelargoniums, generally speaking, require but little water in winter.—**Acklan.**—We do not know of a book that will help you. Send in here any queries you wish.—**J. M.**—No; lamps may be used with rare in a conservatory.—**Tou-tou.**—Apply to A. U. Hitler, Esq., The Lilies, 124, Beckenham-road, Beckenham.

BEEES.

5261.—Management of Bees.—Unless absolutely necessary, it is not good policy to feed Bees in mid-winter, and the only safe food to supply to newly colonies now is sugar-cake or honey, which should be placed over the feed-hole on top of the skep, and covered up warily. It is made by boiling about three pounds of loaf sugar with about half a pint of water until it will set hard upon being suddenly cooled. It is then moulded into any desired form, and in half an hour is ready for use. If not inclined to make it, a substitute will be found in the ordinary sugar-candy of trade. The amount of stores required by a colony very much depends upon the manner of wintering it; the less adequate the protection from cold the greater is the amount of food consumed. Strawskeeps require careful consideration when their provision for winter is being attended to. Judging the contents by lifting is not always safe, as age of combs, pretable amount of pollen, &c., has to be taken into account. The wintering of Bees in straw-hives is, however, attended with much less trouble and risk than in frame-hives, although the latter are much to be recommended in the intelligent management of Bees, as in them we have complete control over the inmates, we can interchange the combs and Bees from one hive to another, examine a stock in a few minutes, make artificial swarms, rear queens, remove full combs in the honey season, extract the honey from them and replace them in the hive to be refilled, and save the Bees the labour of wax production by furnishing the frames with comb foundation. Any swarms that may leave the skeps next season should, therefore, be put into bar-frame-hives, if "Young Beginner" wishes to be up to the times in advanced Bee-keeping. A south aspect is very good, but south-east a little better, as the Bees get the morning sun earlier in this position.—**S. S. G., Sharnhurst, Newton.**

POULTRY AND RABBITS.

5262.—Poultry keeping.—I should say that while not being actually "injurious" to setting hens to be in total darkness, it is better for them to be in a small quiet place with light and ventilation. The best food for all fowls during the winter months is a good hot breakfast of boiled Potato parings and table scraps chopped, mixed very stiff with Sharp's Spratts, or Old Cheddar food, and a little poultry variegated added about twice a week. Their next meal should be of mixed corn about 3.30 p.m., and it is a good plan to put some corn down after dark for the fowls to have as soon as it is light in a morning. The straying hen should be caught and penned up for a few days—in fact, my experience proves that fowls are best confined to a run during cold weather.—**NANCE.**

BIRDS.

5340.—Canaries.—Will someone be kind enough to give me a few hints on the rearing, breeding, and management of Canaries? Also how I may tell the cock from the hen bird?—**BEAR.**

"Gardening Illustrated" Monthly Parts.—Price 5d.; post free, 6d.

"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volume. Price 6s. 6d.; post free, 7s. 6d. Complete set of volumes of THE GARDEN from its commencement to the end of 1892, forty-two vols., price, cloth, £30 12s.

SUMMER FLOWERS FROM SEED.

THE propagation of plants from seed to assist in brightening the flower garden at different seasons of the year is now so general, that a summary of things required for various purposes through the summer months is an essential feature before the dispatch of the seed order. I mention for "various purposes," because plants raised from seed adapt themselves to many requirements—for climbers and trailers, as Cucubers and Marandayas; for sub-tropical work, as Acaecias, Tubaccos, Wigandias, and Solanums; as substitutes for other bedding plants, as Asters, Marigolds, dwarf Calceolarias, Lobelias, and Phlox Drummondii; for summer and autumn cutting, as Sweet Peas, Annual Sundewers, Chrysanthemums, and Dahlias; and for bold massing in outlying shrubberies, as Camellia, Mignonette, Cornflowers, and Clarkias. The subjoined list is necessarily somewhat curtailed, but I think it will be found fairly comprehensive, and all plants enumerated therein are of easy culture. Not many decided novelties were to the fore last season. Probably one of the most striking is the Butterfly Pea (*Centrosema grandiflora*). It should prove useful for covering trellis work of every description, and if also a good trailer, will be grand for the fronts of boxes and the edges of raised beds. Nearly the same remarks apply to the variegated Japanese Hop; this will prove a decided acquisition if sufficiently pronounced in colour. The new forms of Iceland Poppies (both single and double) will be valuable for cutting, so also will the two white flowers—Guletin White Pearl and the White Margarita Carnation.

MANY novelties are announced in Sweet Peas, but an investment in collections of new varieties is rather an expensive luxury, and really good things are obtainable from mixed packets. Of rather older sorts, Mrs. Sankey and Princess Beatrice are two lovely flowers. Many other things may be found catalogued as novelties, of which some few doubtless deserve the name, whilst others, although in a certain sense new, often represent only a really good strain of things already in commerce. Turning briefly to the general collection, it will be found that among the best bedding annuals are dwarf Marigolds, China Asters, and the newer forms of Calceolaria, Phlox Drummondii in various colours, Double Zinnias, Petunias, and East Lothian Stocks. All the larger seedling things can be sown on a prepared bed in a slight warmth; very fine seeds, such as Petunias and Lobelia, are best in boxes. The Stocks should be sown in August, transferred to pots or boxes, wintered in cold frames, and if planted out as soon as the weather gets a bit settled in spring they make a grand bed, and are also valuable in a cut state. All the above are useful for filling beds previously occupied with spring flowering stuff, and have, with the exception of the Asters, a lengthy flowering season, a feature which renders them much more useful for this particular purpose than annuals of equal beauty, but which are comparatively short lived.

IN COMING SEASONS for summer and autumn cutting, Sweet Peas, Digitalis, and the first

place. They should be sown early in deep-lying and prepared ground, be protected from the attacks of birds till well up, and during the flowering season all seed-pods must be promptly and thoroughly removed. Poppies are now in great request, and are special favourites in a cut state all through the summer months. I should place Gaillardias and the annual single Chrysanthemums (*carinatum*) very high on the list for cutting. They are of easy culture and stand well in water. The new race of Comet Asters is also useful, and a hatch of seedling Carnations is indispensable. Of stronger and taller plants the miniature single Sunflower and Helianthus citrinus are very useful, although gardens that boast of grand clumps of the perennial types may hardly require them. Dahlias, both single and Caetins, are now largely treated as annuals, and the flowers are useful for tall vases. Besides these things enumerated earlier in these notes as valuable for sowing in quantity on shrubbery borders and more secluded parts of the flower garden, may be included Eschscholtzias, Linum, Whitavia, Nasturtiums, and plenty of Mignonette. Into the question of plants for sub-tropical gardening it is hardly necessary to enter at length; they are used but sparingly in the majority of gardens. Eucalyptus globulus and E. citriodorus, Acacia lophantha, Nicotiana glauca, one or two Solanums and Wigandias, and Ferns gigantea are a few good things easily grown. Plenty of Nicotiana glauca must be provided; this is about the most valuable acquisition we have had in the last ten years. Two fine foliaged plants of dwarf habit obtainable from seed, and that are always useful, are Dell's Crimson Beet and Contourea rugosa.

THE LATE SEVERE FROST AND GREENHOUSE PLANTS.

THE frost of the night of the 4th of January put to the test the merits of the glass-house heating apparatuses in this locality. In a house heated by a flue I found in the morning every plant frozen, except those actually standing on the flue. I put as many as I could under the stage, and covered the rest with paper. Although I kept up a good fire the whole of the day, I could not thaw the frozen soil in the pot. On the same morning I was in a house (belonging to a market-gardener), heated by two rows of pipes, which the owner thought (the house being low) would be sufficient to keep out frost. The pots were then frozen on the stage, although the pipes were nicely hot. Things were all right in other houses with four rows of pipes. One remarkable thing in connection with this frost is the exceedingly small damage done to vegetation (generally) standing in the open ground. Stocks, Wallflowers, hardy annuals, Canthflowers, Chrysanthemums, and other things that have suffered severely in winters when the minimum temperature has not sunk nearly so low now show but little effects of the ordeal they have been through—in fact, there is scarcely anything destroyed. How is this to be accounted for? Must I not attribute this wonderful preservation of plant life to the weight of the snow? Not that it shields it

from the severity of the frost, as the snow here did not begin to fall till after the minimum point was reached. It doubtless acted first by checking the action of the thaw by causing a more gradual rise of temperature, and, secondly, at the same time shielding it from the injurious action of light. I am inclined to think that paper coverings act much in the same way. When I banked up the fire for the night of the house with a flue above referred to, I put a newspaper, which I had at hand, over some of the Cinerarias in the house. In the morning I found them frozen along with the rest, and after the thaw I could not see that they were looking any better than the rest. There were three dozen of them. They all looked the worse for the freezing, but only two were killed outright. A dozen had the growing points nipped. Half-a-dozen Pelargoniums in the most exposed part of the house were destroyed, and three or four of the Heliotropes, but all the rest I saved. During the hard frost of three winters ago I saw some paper put over some rooted "Geranium" cuttings. When the thaw was completed it was found that a good number of these had survived, while all those "Geraniums" that were not covered, and everything else in the house except some Indian Azaleas, had succumbed to the rigours of the long frost. By-the-way, I have proved on other occasions that Indian Azaleas will stand several degrees of frost. These facts are another proof of what has been so often taught in GARDENING—that many frozen plants might be saved if treated properly during the thawing.

L. C. K.

WINTER flowers.—Saturday, January 13th, was a lovely day here, more like April than January. The Bess of my large apirny were out in full force, humming round the beds of Snowdrops and Yellow Aconites—planted and blooming in loveliness in the Grass—and curling over the drooping racemes of the white of "White" Erica carnea growing near to them. A nice mass of Cyclamen europaeum has been in bloom since the middle of December, and though during the severe frost they lay prostrate, the flowers are now bravely erect, no worse, apparently, for the visit of the recent frost. In a corner in sand there is a nice lot of Iris reticulata, which are now 6 inches high, and are very vigorous. The position is a dry one, and they are growing in sand, such as composes the banks along the seashore of Cumberland and Lancashire, with a very little of the staple garden soil mixed with it. These "winter" flowers are indeed precious to the lover of the simple beauties.—JAMES STONEMAN JESSE, Kirkbride, Silloth, Cumberland.

529th. — *Lysimachia Nummularia aurea*.—This is a yellow sport from *Nummularia*, and it is doubtful if reliable seed could be obtained. It is true the Golden Feather is a sport from the common Green Feather, and the Golden Feather comes true from seed; but the *Lysimachia*, in many cases, does not seed freely. At any rate, there is no difficulty in getting the plants, and they soon spread, and may be rapidly increased by division.—E. H.

ROSES.

SCOTCH BRIERS.

The varieties of our native *Rosa spinosissima* are quite hardy, and if only the ground be well broken up and manured when the plants are first put in, Scotch Briers are better able to take care of themselves than any other kind of Rose of garden origin. Climbing Roses want training and tying; Hybrid Perpetuals require pruning and mulching, not to mention the keeping down of aphids and milliw; Teas and Noisettes need protection in winter, but Scotch Roses, if carefully planted at first on their own roots, need neither pruning nor protection, training nor top-dressing, are victims to neither green-fly nor milliw, and, in fact, may be trusted to thrive without any special attention for a considerable number of years. These Roses are not at all particular as to soil, but if it is very poor a light mulching of short manure in November will keep them in good condition. They should be planted in a place by themselves, when they will throw up their spine-covered suckers freely from the base, and soon entirely cover the ground, and as they do not grow more than 2 feet, or at most 3 feet, in height, they thus make a very ornamental mass, flowering freely at every joint. Indeed, their freedom of flowering tends indirectly to render them

maintained in the globular flowers of the more double varieties, while in soils and situations where the successful cultivation of most other Roses would be hopeless, flourishing plants and flowers in abundance may be had of the Scotch Briers.

5325.—**Climbing Rosess in pots.**—You need do simply nothing to the plants, either in the way of mulching or pruning. When the shoots you mentioned have bloomed, cut them back to about 6 inches from the base and keep the resulting growths as clean and healthy as you can. They will then bloom well the following year. Always avoid heavy feeding, in the form of mulching and liquid-manures, until the soil is somewhat exhausted. Plants thrive better when their food is assimilated almost as applied, and the overabundance too many amateurs affect is often the cause of partial failures. —P. U.

5331.—**Marschal Niel Ross.**—A pot 6 inches in diameter is not large enough to get this Rose to flower in satisfactorily, nor will you get a full measure of success from one 3 inches larger. You would do better by putting it into a large Rhubarb-pot, as you suggest, if you can find room for it in any other position in the house than under the stage. With regard to the stock losing its back and looking rusty, that is not of much consequence. It will be

is to let there be no Grass immediately round the stem, and the reason is obvious, as turf keeps away light, the freshening influence of rains, and deprives the roots of a certain measure of sustenance.—C. T.

— This is such a vigorous-growing Rose that it does not matter much whether turf should be removed from over the roots or not. In the case of any other Rose it is desirable to do so.—J. C. C.

— When a good-sized bush has been formed the roots may be buried over without injury; but to guard against injury from the mowing-machine it may perhaps not be advisable to bury close up to the stem.—E. H.

5327.—**Roses in pots.**—The Roses will not take any harm from the treatment, although they would have been all the better if they had been left out in the open for another two months, if the frost had been kept from the pots. The top-dressing, at the time you state, with guano was a mistake. If you had waited until they had shown their flower-buds it would have done me more good. I like to prune and top-dress fl. P. Roses growing in pots, that are not to be forced early, about the middle of December, and unless they can have quite a good-house, they are better in the open air. The buds and the Roses will do very well together.—J. C. C.

— I do not see how "Londonderry" could possibly have done better than he has. Roses and the bulbs he names are eminently suited for the same temperatures. Avoid too great heat for a time longer, and then attend to watering and syringing the young Rose growth, and I feel sure he will realise a highly creditable and satisfactory crop of bloom. I would keep as near to the following temperature as possible: Night, 40 degs. to 50 degs.; day, 50 degs. to 65 degs. Much of this must depend upon the weather, the higher points being reached upon mild and bright periods.—P. U.

5328.—**Forcing Rosess for cut bloom.**—Unfortunately I cannot put my hand upon an issue for Dec. 30, so cannot answer "M. E.'s" query so fully as I would wish. Under these circumstances I can only ask him to kindly repeat his query if the following does not suffice. Climbing Roses of the Marschal Niel type may be planted 6 feet or 8 feet apart, and limited to three rods each. This will give 2 feet of roofing to each rod. When in pots or the side borders, I would arrange them so as to afford this space to each rod; but in the case of pot plants one rod to each would be sufficient; thus needing about three times the number of plants.—P. U.

5276.—**Making a propagator.**—A cheap and simple propagator for raising seeds, &c., may be made in the following way: Take a packing-case about 15 inches deep; remove the lid, and nail a piece of sheet iron (which can be bought from any ironmonger's) in its place. Next cut a piece out of the side of the box large enough to let the lamp pass in and out; this must be covered over with a door to keep the warmth in, but holes must be bored round the top of the box for ventilation. On the top of this another box must be put the same size, or smaller than the first, 7 inches deep in front, and sloping slightly up. This must be covered by a light, which can be made by anyone with a saw, a screw-driver, and some screws. To make it cut some strips of wood (part of the lid of the box would do), two strips 2 inches wide and the same length as the box, add two more strips 2 inches wide, and 3 inches shorter than the width of the top of the box. Next cut two strips 1 1/2 inches wide, and 4 inches longer than the end strips, and one strip, 1 1/2 inches wide. Screw them together firmly, and hinge the light on to the top of the propagator. If the space seems too big to be filled by one pane of glass or more, sash-bars may be made of two strips. The lamp for the propagator should have a low tin tank, a duplex burner, and a glass chimney. It would cost about 3s. 6d. at an ironmonger's. Ordinary paraffin lamp-oil is the best to use, and if any carbon which has collected on the sheet iron is rubbed off whenever the lamp is trimmed it will do no harm. The top box of the propagator must be filled with sand, Moss, Cocoa-nut-fibre refuse, small pieces of turf, or anything that will hold moisture for long. The pots for seeds, &c., must be plunged in this, and it must always be kept damp.—H. G. ILLINOIS AT

Rose "Scotch Brier."

essentially garden Roses, as opposed to Roses for cutting, for in addition to their innumerable thorns, which make them somewhat uncomfortable subjects to handle, the flowers are so freely produced that they are liable to be inconveniently short-stalked, unless an entire wreath be gathered. It is true that the Scotch Briers are only summer-flowering, but then their delightfully fragrant flowers come so long before the generality of garden Roses that they are especially welcome. Moreover,

ONE OF THE PRETTIEST and most sweet-scented varieties is a perpetual, blooming a second time in autumn. This variety was raised at Stanwell, and distributed under the name of the Stanwell Perpetual. In habit and appearance it is not very different from the summer-flowering varieties, but its pretty globular lush flowers, of a most delicious fragrance, are freely produced both early and late, it being no uncommon thing to find them in good condition during October. Numerous varieties have been distributed at various times. These Roses are now hardly ever referred to or even obtainable by name, being, as a rule, merely described according to colour, as white, pink, yellow, &c. There are, unfortunately, in cultivation many very dingy-colored varieties, which have got these Roses a bad reputation from a decorative point of view. Nothing can be more charming than a mass of these dwarf, delightfully fragrant and very hardy Roses, whose buds are in miniature the perfection of form, a quality which is

better, however, if when repotting it you bury the whole of the stock and about 2 inches of the stem of the Rose. If you make a barrier for the roots you may plant it in the conservatory, and the growth may be trained to the wall until it reaches the glass; but whether the growth in the wall will flower depends on how much light and air reaches it to ripen it. There is no reason, however, why you should not succeed with it in the span-roof house if you give the plant more root space in a fairly light position. I may here tell you that I quite agree with "J.'s" statement that the only profitable way of growing this Rose is to plant it out in a border of good soil.—J. C. C.

5221.—**Rosa rugosa on a lawn.**—I suppose from your query that you are doubtful whether it would do to allow the turf close up to the stems of the Roses. The roots of Grass penetrate to an almost incredible depth, so that they naturally rob the soil to the disadvantage of the Rose. A further reason why I would not have the turf quite close to the plants lies in the great benefits accruing from slight surface culture; this is obviously impossible without injury to the turf; therefore, keep a neat and well defined edge around the plants.—P. U.

— This Rose would take no harm from having the turf up to the stem, but it would be better to have a space of soil round the bush, as though a top-dressing of manure or a good soaking of water may be given during the summer months. In the case of all trees, the better way

HOUSE & WINDOW GARDENING.

5301.—Creepers for a window.—The dwarf forms of Nasturtiums are wonderfully showy when hanging over the front of window-boxes, as also are Petunias. As you want a variety the Canary Creeper is very suitable, so is the little evergreen Virginian Creeper. Nierenbergia gracilis is exceedingly free flowering, and quite a change from other plants. Convolvulus major in variety is frequently used for this purpose, and in sheltered windows the drooping forms of the Tuberous-rooted Begonias will not fail to please you. Root to these the trailing forms of Ivy-leaf Geraniums and you have a good variety.—J. C. C.

—Creeping Jenny (Lysimachia Nummularia) is a capital plant for covering the fronts of boxes in town. Ivy-leafed Pelargoniums, Lobelias, and Nasturtiums are all useful.—K. H.

—The best of all flowering plants to hang over the sides of a window-box is the Ivy-leaved Pelargonium, which is well adapted for the purpose, its long shoots being wreathed with flowers through the best part of the season. It is most satisfactory in every way. The Creeping Jenny is another good plant to use, and if you plant good pieces they will grow quickly, and hang down over the box; their green shoots are surfeited with yellow flowers in the summer. Or you could get some of the small-leaved Ivies, and these are less stereotypical. There are also Campanulas, as C. isophylla alba, C. carpatia alba, or C. garganica; but these will not grow so quickly nor make such a perennial show, so to say, as the Ivy-leaved Pelargoniums.—C. T.

5311.—Room plants nipped by frost.—Take the plants to a warm greenhouse if there is one for a time till new growth is obtained. If no such convenience exists keep the roots just a little drier and wait patiently. The plants will probably shoot up again from the bottom if not too badly frozen.—K. H.

—I am sorry for your mishap, as I am afraid that the prospect of a good bloom is destroyed. Your only plan is to remove the plants, if possible, to a greenhouse, moderately heated—sufficiently so, at any rate, to keep out frost. They will start again, and it depends upon to what extent they were damaged as regards future blooming. From your query I am afraid it is hopeless. Remove the dead leaves, and with gentle warmth they will soon recover.—F. V.

TABLE PLANTS.

BERRIED SOLANUMS.

These are most valuable for table and general room decoration during the autumn and winter. Intending growers should bear in mind that the seed of these Solanums (S. capsicastrum var.) cannot be sown too soon after the beginning of the year, to obtain plants of a suitable size and well furnished with berries. Unless there is a

Berried Solanum.

temperature of 50 degs. available it is, however, of no use to sow very early, for the seed will not vegetate satisfactorily in a lower temperature. As soon as the seedlings are large enough they must be put into small pots, in which they should remain until the soil is full of roots. The easiest way to grow them is to plant them out at the end of May, in a bed of soil, in a frame, where they can have the protection of the lights for a few weeks. In the autumn they must be taken up and put into pots, and shut up again in the frame, until they will bear being sir and sun without being injured. Early in the

autumn they must be taken into the greenhouse, and in due time the berries will assume their proper brilliant colour. B.

5299.—Table plants.—There is no general rule as to the height of these now. Many years ago, when prizes were offered by the Royal Horticultural Society, the rule was for the plants to be grown as standards with 18 inches of clear stem, so that the guests could see each other beneath the foliage; but such plants were gawky and inartistic, and nobody of any weight followed the lead, and the most useful plants now are Feathered Palms, with small variegated Grasses, and similar light, graceful things of different heights to suit different tables and positions, and a good deal is done with foliage and flowers in the clothes. In growing table plants for exhibition sometimes the schedule states the size which must be exceeded, or else they are confined to a particular size of pot. The pots usually selected for table plants are 5 inches in diameter, but it is often found that Maiden-hair and other Ferns may be used in still smaller pots with great advantage, and such things as Fittonias and Mosses may be used in pans for a change.—K. H.

—You must abide entirely by the schedule in such a case. As far as I know, and I am acquainted with the majority of societies, there is no such rule, but many societies have their own characteristics. It would be well if table plants were always kept down to a certain height and used more sparingly than is the case too often. They are a hindrance to conversation between guests at dinner.—C. T.

—I never heard of any rule limiting the height of table plants, although it is well understood by good judges that they should not be too dwarf or too tall. Twelve inches above the pot is a safe rule to follow. The safest plan to adopt is to consult the rules of the particular show you intend to exhibit at. If no height is given you may follow your own inclinations. You must, however, understand that there are other points besides the height that have to be considered.—J. C. C.

—I have not heard of any rule as to the height that table plants shall bear any exhibition. This is a matter always left to the discretion of the exhibitor. Some judges favour very small plants, not more than 9 inches high from the top of the pot, while others consider they should be not less than 12 inches or 15 inches in height. Plants 1 foot high from the top of the pot, which ought not to be more than 6 inches in diameter, are very suitable for the majority of tables. For a large dinner party, where the table is of extra length, it would require taller plants, of course. A point of more importance is to select suitable kinds and as much variety as possible. In a collection of six plants there should not be more than two Crotons, a red and a yellow-leaved one. No chuss of plant is better adapted for dinner-table decoration than Crotons. They are not only light and graceful, but the rich markings of the leaves show to perfection under artificial light. In all cases the plants should be of a single stem, with perfect leaves shown to the top of the pot. Dracena gracilis, Andin Veitchi, Cocos Wobbellium, and a well-coloured plant of Pamlans Veitchi would make a capital six.—S. P.

5301.—Cow-manure.—Do not get anxious about the cow-manure killing your Rhododendrons; it will do them more good than harm, especially if it had been lying some time exposed to the weather. Some peaty soils are very poor. If you are of that description you may repeat the application once a year with manifest benefit to your plants. I have found that in a good loamy soil the plants liked a top-dressing of some fine material that washed away into a kind of powder. It is surprising what a lot some people know. I do not, however, object to their superior knowledge if they did not disturb the peace of mind of other people without a cause.—J. C. C.

—Unless it was put on in a very rank state it will not hurt the Rhododendrons. When Sir J. F. Llewellyn lectured at one of the Royal Horticultural Society's meetings last summer, he said that no manure was needed by Rhododendrons; but a gentleman who took part in the discussion which followed said that in his experience and dealing with a soil not adapted to the plants, he found good results followed from the use of cow-manure. A. H.

INDOOR PLANTS.

CAPE PELARGONIUMS.

We very seldom meet with these most useful winter-blooming plants now. Some ten years ago I had a fairly good collection, and I have seen them in fine form at Messrs. Cammell's nursery a few years back. I do not remember just how I lost my own, but they are all gone now. Their extreme usefulness was very forcibly brought to my mind when looking over

Cape Pelargonium "Pretty Polly."

a neighbouring garden at Christmas. In every respect these are unique and showy little plants; they are billians rooted, have very pronounced prickles, and the foliage is almost as strongly perfumed as the Oak-leaf and other scented Pelargoniums. P. echinatum, the type, was introduced from the Cape of Good Hope about a century back, and has trusses of white flowers, spotted and striped with deep maroon upon the upper petals. A variety of this under the name of Spotted Gem has rose-purplish as a ground colour, and is spotted with deep-crimson. It is a more compact truss, but not so close habitually a plant. Pixie, Beauty, Ariel, and Pretty Polly (here figured) are all distinct and good. I do not know how to describe the flowers of Ariel better than likening them to trusses of the old Unicorn, only more elastic in form and colouring. All through the late autumn and winter these Pelargoniums are most profuse flowering. When spring flowers are plentiful, strikes the young growths like the ordinary Pelargonium, and grow them on freely. I used to stand them in the sun on an open border from July to September, keeping them rather dry at the root and so securing wool almost ripe enough to cast its leaf. When introduced into heat in the autumn they bloomed profusely until March and April, when they were then propagated from. P. U.

5320.—Plants suitable for growing with Ross in an unheated house.—"Lewishamite" will find all of the following suitable for his purpose; but there are far too many which might be used to admit of a complete list being given: Spirea japonica, Dentzia gracilis, Lily of the Valley, Hycanthus, Tulips and other bulbs, Azaleas (both the Indian, Ghent, and Mollis sections), Camellias, Ixias, late Chrysanthemums, Carnations, Bonanias, and heaps more. I do not say they should be allowed to stand frost while in full bloom, as at this time Roses are in young growth, but the unheated house should form sufficient protection from frost. There are many foliage plants which would look well in the house during winter, and before other subjects come into growth. Osmanthus, Berried Aucubas, Solanums, Variegated Alms, and others would look well and benefit for the little protection until the sharpest of the spring frosts are past. Erica, Emmerises, and a few of the better forms of highly Heaths, such as E. carnea, E. vagans alba, and the Cyclonia japonica and its

varieties, *Chimonanthus fragrans*, *Myrtle*—in fact, a vast number of subjects are quite suitable for an unheated house and will form attractive companions to the *Roses*. The *Boissardias*, for instance, would make new growths from older wood which was sufficiently hard to stand a slight frost.—P. U.

5313.—**A saddle boiler.**—By "anno other material," I suppose you mean asbestos; but I do not think—in fact, I am sure—that it is impossible to heat a saddle boiler satisfactorily in this way. A properly constructed copper boiler would give far better results, however, at much less cost, certainly, when the cubic contents of the houses exceed a thousand cubic feet, as in this case. You had better get a good catalogue of gas-heating apparatuses.—B. C. R.

Probably with a very great waste of heat any sort of boiler could be heated with gas, but the proper thing is to have a boiler constructed on purpose for gas. I cannot, however, advise you to attempt the use of gas in this case; it would be much too costly. With a saddle boiler properly set and good coke or anthracite coal you can heat the two houses more economically than by any other means. You had better call in a skillful engineer in the first place to advise you about the position for the boiler and pipes.—J. C. C.

5208.—**Coleus-cuttings.**—These will strike freely at any time of the year; but if wanted for the summer conservatory decoration I should advise "J. E. J." to take his cuttings in the middle of the following month (February), as they will strike quicker and make better specimens than if inserted now, for if taken too early, one stands the risk of losing their under-leaves, which spoils the appearance of the plant. *Coleuses* thrive well in a compost of one-half good loam, one-fourth thoroughly rotted cow-mannure, and one-fourth good leaf-soil, with addition of a little sharp sand to keep the whole porous. Great care must be taken that the plants never suffer for want of water. Cuttings are best inserted separately in small pots, placed in a bottom-heat of 70 degs. As soon as the roots touch the side of the pots they may be shifted into larger ones, pinching out the end of the shoots occasionally to secure bushy plants. When well established a little liquid-manure is very beneficial.—F. T.

5105.—**Treatment of Cannas.**—Turn the plants out of the pots, remove all the soil from the roots, and divide them. By pulling them into pieces, every bit with a root attached will grow and make nice plants in a few months' time. Place each piece separately in pots of suitable size; those in which the roots will grow comfortably are large enough. A compost of loam and leaf-mould filling this latter, horse-mannure will answer with a little peat added—three parts of loam to one part of the leaf-mould, adding sharp silver-sand, according to the state of the loam, heavy or light. Stand the plants in the greenhouse, giving just sufficient water to prevent the soil becoming quite dry until growth is fairly on the move, when abundance of water will be advantageous. Do not dry them off with the idea of losing their leaves; the plants cannot carry too much foliage. When the plants are freely growing during the summer syringe the leaves once a day at least; this will keep them healthy, and free from dust and insect pests. S. P.

Divide the roots into pieces consisting of one strong crown, or two or three smaller ones, pot them singly in 3-inch or 4-inch pots, using good rich sandy loam, and start them in a gentle hot-bed, or in any warm-house or pit. Shift on as required, harden off in May, and plant out early in June in deep, rich soil and a sunny situation. The plants would have been all the better for going to rest for a short time, but it will not make very much difference to the growth. There is time enough to divide them yet. March will be quite soon enough, especially if you have not much heat at present.—B. C. R.

5314.—**Plants in a cold frame.**—I wonder you have been able to keep "*Ceraninus*" in a cold frame without artificial heat, unless you protected well, but take care in the future. You must not let any of the things mentioned get dust-dry, particularly the *Ferns* and *Chrysanthemums*. On mild days, such as the present, a good opportunity is given of watering freely. If the *Chrysanthemums* are permitted to go dust-

dry for any length of time they never recover satisfactorily, and always feel the effects of this neglect. Still, be careful not to go to the other extreme, and splash the water about anyhow, as this engenders damp, which means, in the winter in particular, decay.—F.

5310.—**Sowing seeds of Callas, &c.**—The seeds of the *Callas* may be sown in the hot-bed at any time now. If well grown they may flower next year, or some of them. I have had them flower in twelve months from the seed, but the flowers are generally small on seedlings at first. Seeds of *Genistas* may be sown in the hot-bed or in a warm greenhouse any time during spring. All the plants named may be bought cheaply now.—E. H.

Sow the seed at any time now in a pan of sandy loam and peat, placing in heat and keeping moist. The plants will probably not flower till the third year at least. Seeds of the *Genistas* should be sown in March or April, using sandy loam and leaf-mould; seedling plants do not bloom an soon or so freely as those from cuttings. If you want a large or considerable number, the best time to lay them would probably be in the autumn, when such things can often be picked up at the large trade sales very reasonably.—B. C. R.

WINTER GARDENS.

Nothing is more pleasing in the whole range of gardening than the effects which may be produced in a tastefully-arranged and well-kept winter garden. We are therein enabled to give some slight idea of the general aspect of tropical and other vegetation. The house itself need not necessarily be a large one; indeed, one of the prettiest winter gardens I ever saw was very small. It had been built for a lady in infirm health, and was attached to the dwelling-house. In it was nothing rare or tender, but the subjects were suitable, tastefully arranged, and the hands of the owner herself kept them healthy and clean by means of frequent washings and spongings. Many an hour was thus pleasantly spent in the exercise of a boring cure which had its reward in the bright appearance of the

&c. In the latter we get a strong tinge of tropical verdure to the arrangements by employing *Palma*, *Pandanus*, *Strelitzias*, *Brownias*, &c.; some of the *Tree* and other *Ferns* can be tried. The great mistake made in winter gardens is overcrowding; it is often just the same here as in outdoor planting, thinning is not done in time, and the whole degenerates into a weary tangle. Ultimately something must be taken away, with the result of more fully exposing the debilitated specimens. So avoid overcrowding and plant well in the first instance in good soil. It is scarcely necessary to dwell upon the uses and advantages of a winter garden; its name sufficiently indicates the end and aim of its existence—a place of resort when inclination, health, or weather forbids wandering far from home. The annexed illustration gives a good general idea of the arrangements of a small winter garden. C.

5297.—**Libonia floribunda.**—You would scarcely succeed with this in an unheated house as regards winter blooming. To get this we need a temperature of 50 degs. to 55 degs. It will bloom in the early spring with heat. *Libonia perhosiensis* (or *perhosiana*) is by no means the same as *L. floribunda*. The leaves are more acute, and the whole flower much brighter than the one heading this note. In the winter it is a deep fiery-red, and at no time has much of the yellow or orange found in *L. floribunda*.—P. U.

5323.—**Fumigating.**—The best of all fumigations is an oil sieve, having a coarse mesh through which the air can easily blow when the sieve is placed on two 6-inch pots on the floor of the house. The advantage of a sieve over any other utensil is that a greater area is employed for the smoke to ascend from. If a few hot embers are placed all over the sieve and covered with Tobacco-paper, slightly damped, a large body of cool smoke will issue from the sieve and quickly fill a large house. The point is not to allow the Tobacco-paper to blaze; if so the smoke becomes heated, and is thus injurious to the foliage operated upon. While fumigating a house water should always

be handy; in fact, it is best to have a small water-pot handy with a fine rose on it, and upon the first sign of the Tobacco-paper blazing sprinkle the whole with water. Covering the Tobacco when burning with freshly-gathered damp Moss is a good preventive from burning. There is nothing so efficacious as thoroughly good Tobacco-paper bought at a reasonable price; that which is sold at a low figure is seldom of much use. S. P.

You should not have accidents with the flower-pot, if you take care; but the way I used to fumigate was to get an old can and make a fair-sized hole at the bottom in the side. If the Tobacco-paper is not too dry it will not flare up, but there is a special contrivance now which you can purchase, I believe, cheaply. You make everything right beforehand, put it into the house, and leave it there, without fear of mishaps. Of course, in the case of the old-fashioned can or pot attention is constantly required and entering a houseful of smoke is neither pleasant nor wholesome.—C. T.

5295.—**A hanging basket.**—A hanging basket planted with Ivy-leaved *Pelargoniums* is very pretty and lasting. The basket may be filled now and hung up in a

View in a winter garden.

plants. Winter gardens may be placed in two categories—viz., those in which heat is only applied to exclude frost, and those wherein a regular comfortable warm temperature is maintained. It will naturally be seen that the plants used for the two places must be somewhat different in character. In the former we must rely upon the inhabitants of temperate climes, but which we cannot well grow the year through in the open air in this country; such are some of the *Avonarias*, some *Ferns*, also *Ferns*, *Camellias*, *Acacias*, &c.

URBANA-CHAMPAIGN

FRUIT.

5292. **Grafting fruit-trees.**—Whip-grafting is the best method for all young stocks and small branches of large trees after the young stock or branch has been cut back. A thick slice is cut off the side from 2½ inches to 3 inches in length, and made quite smooth. The scions or grafts may be about 4 inches long, and a slice is cut off the bottom to correspond with the cut in the stock, and the two are then fitted and bound together with raffia. The bark of the scion and that of the stock must join on one side, and the more perfect the fit the better the chance of a perfect union. It will be necessary to prepare some soft clay before the grafting is commenced, as the sooner the chying is done the better, and it should be so fitted round the wounded parts as to perfectly exclude the air. A little chalk mixed with the clay in the tempering will make it hold together and prevent cracking. Successful grafting or budding is very much a matter of selecting the right time. The best time for grafting is just after the sap has commenced its upward movement in March. Some seasons grafting may be done early in March, and occasionally it may be done to better advantage in April. Meet the sap in its full flow, and very few grafts will fail. In the grafting of large trees the tops should be sawed off to within a foot or so of the place where the grafts will be inserted before the sap begins to rise. For instance, all trees intended to be grafted this coming season should be cut back now, and the scions should be cut from the trees intended to be used as grafts and laid in under a north wall to keep the buds from starting, as it is better for the stock to be in advance of the graft. Whip-grafting is not suitable for large trees in most such cases. Graft, wedge, or ring-grafting is adopted; and usually two or more grafts are placed on each branch according to its size. In wedge-grafting a niche is cut in the top of the stock across its centre downwards. The saw should be set wide for this work. The grafts are made in the shape of a wedge, and may be of more than one year's growth, and are driven in tight, one on each side of the stock, with the bark of each in contact. In ring-grafting the grafts are cut smooth on one side, the bark is removed on the other, and the grafts are then thrust down between the bark and the wood, the smooth, flat side being next the wood. In windy places it is necessary to secure the grafts with sticks as soon as they begin to grow, as the wind may dislodge some of them.—E. H.

5317.—**An old Pear-tree.**—As the tree here a large quantity of fruit the roots cannot require pruning, which is the usual remedy to adopt when fruit is sparsely borne. Some fresh soil and manure might be worked carefully in amongst the roots for at least 10 feet away from the stem. If available, liquid-manure should be poured on to the roots in quantity any time between now and before the tree comes into bloom, choosing dry weather for the work. From fifty to one hundred gallons would not be too much to give the tree at once; all the roots have then a chance of being stimulated in consequence. The tree should receive nourishment also when the fruits are swelling. If the weather be dry and liquid-manure not available, cover the ground for several feet away from the stem with half decayed horse or cow-manure, and give the trench thorough soaking of clear water. The juices from the manure will then be washed down to the roots.—S. P.

5302.—**Lean-to house for a Grape.** **Vine.**—Presuming that the Vine is growing against the back wall, and is to remain there, Climbers and Tea-Roses may certainly be grown in the front part; but it will be too hot and sunny for a Lageria to do much good, as this plant revels in shade and moisture. If the Vine is trained over the roof neither Roses nor Oleanders will do much good; but Lagerias or Camellias may then be grown on the back wall.—B. C. B.

5305.—**Best market Melon.**—My advice, based on experience, is not to have anything to do with Melons for market. They are imported in immense quantities for cheaper than we can grow them. In nine cases out of ten the consumers will pay better.—B. C. B.

5304.—**Winter Apples.**—After the swelling process is over, wrap each Apple in soft paper, and pack in barrels or boxes, and place the barrels in a dry place or in any dry cool room where the light is not bright. The Apples will come out in splendid condition in March.—E. H.

GRAPE MUSCAT HAMBURGH.

It is much to be regretted that this high-class Grape is often unreliable. At its best it is of taking appearance, and is so much appreciated that it would rightly be placed before any other black variety in open competition, the Muscat flavour and aroma being even more pronounced than in the case of the Muscat of Alexandria. Mr. Barron in his "Vine Culture under Glass" states that it is a very old variety. For a time it was lost sight of, but was again brought into prominence by Mr. Snow, who named it Snow's

Grape "Muscat Hamburg."

Muscat Hamburg. Being well advertised, if I remember rightly, by Mr. A. Henderson, of the old Pine-apple Nursery, there was a very great demand for planting Vines, and it was thought that overpropagation was the principal cause of the variety failing to do well at the outset, but a longer acquaintance with this Muscat Hamburg demonstrated only too conclusively that no reliance whatever could be placed on it. Rather more than twenty years ago, Mr. Venn, living near Bristol, caused some sensation among Grape growers by showing repeatedly very superior bunches of a black Muscat-flavoured Grape under the name of Venn's Seedling. Each time I saw these exhibited I was much impressed with them, the bunches being medium-sized and compact, the berries fairly large, oval in shape, perfectly black, and richly flavoured. Evidently numerous other gardeners also formed an equally good opinion of Venn's Seedling, as large numbers of Vines were bought, planted, and in the course of two or three seasons cut out again owing to its soon being discovered that it was an old acquaintance under a new name. That the true old Muscat Hamburg can be grown to perfection in some few places there is no gainsaying, and if we can discover what conditions are most suited to

its requirements this will be a step in the right direction, as there are numerous gardeners who would be only too pleased to succeed with the variety. Mr. Goodlaere at Elvaston Castle, near Derby, has been the most consistently successful with this fickle Grape, and both in his and other instances where it has done well the soil is of a somewhat strong, retentive character. The latter alone will not ensure success, but it is an important factor in the matter. The variety is not easily grown too strongly, and I have never yet met with an instance of roots in a heated house failing to produce bunches very freely. It is very much the same whether the roots are inarched on the Black Hamburg or any other stocks or are on their own roots. During the first season or two there may be a slight improvement effected, the berries setting more regularly, colouring well, and shanking—but

little; but if there is no "back-bone" to the bonier, or, in other words, the soil is of a light, non-retentive character, a partial or complete failure soon results. A mistake very commonly made is the selection of what promise to be large bunches, but which only too frequently end in becoming mere frameworks. Instead of selecting the largest bunches that show, the wisest plan is to cut these off and save others considerably smaller. Better have a fairly heavy crop of bunches from 1½ lb. to 2 lb. in weight than a small number of great clusters badly furnished with fully-grown berries, and which are therefore an eyesore rather than a pleasure to the grower. Occasionally

EXTRA LARGE, WELL-SET BUNCHES may be met with, but, as a rule, the berries are nearer red than black in colour, while the majority of large clusters give signs of having had far too many small or stoneless berries cut out of them. The small bunches, besides setting and colouring the most surely, are the least liable to shanking—another had failing of the variety. There ought, then, to be no hesitation about either cutting away the large branching clusters, or reducing them considerably, this being done before the flowering period arrives. While they are in flower, a somewhat high night temperature, or, say, not lower than 45 degs., should be maintained, and towards midday artificial fertilisation ought to be resorted to. Supposing the Vines are in a house with Black Hamburg, Madresfield Court, Black Alicante, or other free-setting varieties, some of the pollen from these may well be transferred to the stigmas of the Muscat Hamburg flowers, this being done either with the soft palm of the hand, or, if the hand is too rough and hard for this to be done in safety, a rabbit's tail may be used instead. If the roots are kept active near the surface and overcropping is avoided, these medium-sized to small bunches will colour perfectly in an airy house and no shanking be noticeable. W.

5304.—**Pine-apples.**—Queens of the age named should fruit this summer. As regards repotting something depends upon their condition at the roots. A 6-inch is not a very large pot for a strong Pine, even of the Queen family, which can generally be grown in smaller pots than other varieties. But if they are to have a shift they should soon have it, as some of them will probably soon show fruit, or, at least, they could soon be made to show fruit now by lifting them out of the plunging-bed for a time, and cooling them down, giving all the extra heat afterwards; but under any circumstances 65 degs. at night need not be exceeded at present.—E. H.

5321.—**A Strawberry crop.**—It is simply impossible to answer this question satisfactorily. The yield obtainable from 2,000 plants depends not only upon the soil and season, but upon your experience and treatment as well, and the monetary return will be influenced immensely by the season, the kind of market you have, the system of packing, the distance, and, above all, the time you get the bulk of fruit into the market. President and Dr. Hugg are good kinds, but more of Sir A. Paxton than the former are grown for market, and Noble is just now prime favourite, on account of its earliness, size, and colour, which for market work counts far more than flavour. Further, in some soils certain varieties succeed best, on others, others. Your best plan will be to try half-a-dozen at least of the best kinds, and see which thrives best. If, however, you like to send an exact description of the kind of soil you have to deal with, I will tell you what varieties are most likely to do well.—B. C. B.

5330.—**Vine fruiting in pots.**—I should place the Vines that are planted in the outside border inside theinery toward the end of February, which would be early enough for them to start into growth. In the meantime the house can be utilised for growing plants in, the maximum temperature of 65 degs. being rather too high for Vines at this time of the year. In the meantime cover the roots from frost and excessive rains, first with some stable-litter or leaves, over this putting galvanised zinc or boards; anything that will ward off heavy snows will suffice. In pruning cut back the roots to three eyes above the caves; this allows for one pair of side shoots and a leader above

the canes, thus laying a foundation for the future fruiting of the Vines. All growths below the canes should be rubbed off as they start, thus concentrating the energy of the Vine into the three selected shoots. Pruning may be done at once, measuring the length of stem required to bring it the required length above the canes. No fruit should be allowed upon the canes this year. The pots in which the canes are that are intended for fruiting at once are quite large enough. A piece of turf 2 inches thick may be placed round the inside edge of the pot to provide space for a top-dressing of half loam and horse-manure, with a handful of finely-ground bones mixed. Prune the canes at once to within 5 feet of their base. Half-a-dozen bunches will be quite enough for the Vines to sustain the first year, allowing but one bunch to each shoot. The end of February will be soon enough to place the canes in the house, giving them a position near the front where the rods can be trained up the wires at the front. Pinch the point out of each shoot two joints above the bunch, removing all superfluous bunches early.—S. P.

CHRYSANTHEMUMS.

5306.—**Japanese Chrysanthemums, &c.**—No time should be lost in inserting about sneaker-like cuttings singly in 2½-inch pots in sandy soil, placing the pots under a hand-light on the stage of a coal-house. If the stage is of the ordinary batten type cover it with slates or tiles, laying on these half an inch or so of coal-ashes to exclude air, and provide a cool base for the pots to stand upon. Remove the lights for an hour or so every morning to dissipate condensed moisture from the glass and the inside of the lights, which is a means of preventing the cuttings from damping. Shift the plants into larger pots as required until those 9 inches in diameter are reached. In these the plants are to flower. At all times provide ample space for the plants, so that the growth will be stocky, and not in any way be drawn up weakly. Do not top the plants, but allow them to grow uninterruptedly until the first natural break is made by the formation of a flower-bud at the point of the leading shoot. Remove this bud, and reduce the shoots which will have formed about the bud to three, selecting the strongest, which are those nearest the apex as a rule. Pinch off all other growths so as to concentrate the whole energy of the plant into the three selected shoots. Place a stout stake to each plant, but some distance away from the stem, so as not to interfere with the roots no more than is absolutely necessary. To the stake secure the growths loosely. The bud showing at the point of each shoot, if not before the middle of August, will give the best blooms. With a view to strengthening the selected flower-bud and assisting in its progress all shoots that spring from the nodes below must be promptly removed as soon as they are large enough to handle. A fairly rich soil, pressed firmly into the pots, and abundance of water both at the roots and overhead are points in culture that must not be omitted. The following varieties can be depended on to give good blooms—Japanese Anemone; Queen Elizabeth (silvery-blush, rose centre, tipped yellow), Sir Walter Raleigh (guard florets pale-blush, disc deeper colour, tipped yellow). These two are quite new, but deserving a place in my collection. Duchess of Westminster (long drooping guard florets, silvery-blush, centre very full, rosy-bronze), Sœur Dorothea Souille (blush, white centre, guard rose colour), Phœnix de Médiane (deep-lilac, shaded purple and gold), Jeanne Marty (guard florets, rosy-peach, centre florets tipped white), Marguerit Villagenise (centre white, shaded rose, guard blush), Nelson (rosy-crimson), M. C. Lelecoqz (citron-yellow), Mons. Pankoucke (reddish-orange, bronze-tipped), N. C. Inkes (lovely rose colour, guard petals deeper shade), James Weston (candy yellow centre, guard florets, white), large-flowering Anemone; John Bunyan (candy-coloured guard florets, centre rich-yellow), Mrs. Judge Benedict (tipping light-blush, shading to pure-white, lemon-coloured centre), Sakine (sulphur-yellow, guard florets primrose-yellow disc), Miss Annie Lowe (bright-yellow), Lady Margaret (white), Gladys (pale yellow, brassy-yellow), W. G. Drover (purple-carmine),

Delaware (guard florets white, centre pale-yellow), Georges Saml (bronze-red), J. Thorpe Junr. (rich-golden-yellow), Laing's Anemone (deep rosy-purple, guard florets lilac-rose disc), Mimi. Nathalie Brun (pure-white).—K. MOLYNEUX.

5318.—**Vigorous Chrysanthemums.**—W. H. Lincoln (yellow) is an excellent late-flowering variety when grown as a bush for decoration. Avalanche is not so good, except when the flower-buds are reduced to one on a shoot, and then it answers very well. To flower this variety profusely is to spoil its appearance, because the flower-stems of the side buds are too short to give a graceful appearance to the plant. It is, however, an excellent variety for cutting down. Mrs. F. Jameson is another that is amenable to the cutting-down method, but it is not so well adapted for decoration when flowering in a mass. Leon Fracho is one of the best late-flowering Japanese kinds we have if cultivated in the following manner: Top the plants when 5 inches high, afterwards allow all growths to develop buds at will, not interfering with them in any form. Alberic Linden is suitable for either cutting down or growing as a bush for decoration. Lily Bates is a free-flowering single variety, good, like all single-flowered sorts are, for culture as a bush. Boule d'Or makes a capital late-flowering bush, but is not so good for the cutting-down method. J. S. Dibbons may be utilized for the last-named method of culture. Virginal Moral is one of those free-growing and flowering Japanese sorts that under any method of culture is a success. Gloire du Rocher is free-flowering and better adapted for bush culture than for cutting down. K. Molyneux is suitable for either method. Mr. R. Bahamit is like the bulk of the Inenreel section, better suited for cutting down than it is for decorative use. President Harrison is free-flowering, therefore suitable for decoration. Miss M. Davidson I am not acquainted with.—K. M.

5245.—**Whits Chrysanthemum.**—Klaine is a very good variety in its season, espe-

cellent dwarf-growing sort, but not more than one bloom should be allowed to develop from a single shoot. As a late-flowering variety L. Channing cannot well be surpassed. Lady Selborne is quite equal to Klaine for flowering early in November. Mlle. Lacroix is a capital sort where stiffness of flower is objected to, as in the case of Klaine. Beauty of Kilmouth, as a free-flowering late sort, is not surpassed.—K. M.

—As far as I know there is nothing exactly similar to Klaine, and certainly none that are more free or better for cutting purposes. The nearest in form and colour is, I think, La Vierge, an early flowering variety of extremely dwarf habit. Mme. Louise Leroy is also somewhat similar, and a most useful variety, but rather later than Klaine, and Mlle. Lacroix is another capital kind for cutting, flowering about the same time. The new Mme. Thérèse Rey is said to be the finest White Chrysanthemum extant, but whether it will prove as generally useful as Klaine remains to be seen. As a late pure-white kind I consider Fair Mail of Guernsey still equal to any.—B. C. R.

—Klaine is very difficult to beat amongst White Chrysanthemums, and you cannot do better than select this. There are, however, a number of good ones. Avalanche is a splendid white, free, and useful to cut, also Rysford White, which is even finer, and a lovely kind for cutting is Jane, or Snowflake, a single variety, with large, free, graceful flowers, narrow florets somewhat twisted. It produces, when not too much stopped, sprays of bloom. Ethel is a good late white, also Fair Mail of Guernsey and Mlle. Lacroix; but in spite of many good novelties amongst white-flowered kinds, Klaine ranks one of the best.—C. T.

5319.—**Early and mid-season Chrysanthemums.**—The following varieties will be found suitable by "H. W." for the purpose named. Early flowering: Mme. C. Desgrange (white), G. Wernig (pale yellow), Mlle. Leonie Lassalle (white), La Vierge (white, cream centre), Lady Fitzwygram (white), M. W. Holmes (crimson, tipped gold). Mid-season: Avalanche (white), Virginal Moral (blush mauve), Mrs. F. Jameson (orange-bronze, reverse golden), Chante F. Lurani (rose, frosted white), Mlle. Lacroix (white; pinch the point from the shoot when 4 inches long, and again when 6 more inches of growth has been made), Charles Doria (bronze-yellow). Late varieties: W. H. Lincoln (yellow), Boule de Neige (pure white), L. Channing (white), Golden Gem (rich bronze-crimson, elongating to yellow), Princess Teck (bluish-white, changing to white), Mme. Mezzard (white).—K. MOLYNEUX.

ARCHES IN GARDENS.

The annexed illustration gives a good idea of the pretty effect of a stone archway in a garden when covered with climbing plants. Ivy, Virginian Creeper, Ruess, Honeysuckle, Clematis, &c., may all be used for this purpose with excellent results. Very effective garden arches over walks, &c., may be made with bent wood or iron rods (painted), and covered with Roses, Honeysuckle, &c. These arches are also highly ornamental and profitable when covered with fruit-trees, such as Apples, Peaches, &c.

OUR READERS' ILLUSTRATIONS: Archway in the garden at "Glenwood," Leicester. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. A. Newton, 19, Belvoir-street, Leicester.

cially for cutting, and it cannot be dispensed with. But there are better whites than Klaine now. Lady T. Lawrence, Stanthelm White, and Avalanche are better than Klaine if size and bulk of flower counts for anything; but the varieties named are later, and, therefore, would not compete with Klaine.—K. H.

—It is difficult indeed to name a variety more useful than Klaine, and as easily grown. Klaine White will produce more flowers and is more graceful individually. Avalanche is a

or Phlox. A Vine-clad arch or archway in a garden forms a picturesque object and very agreeable shade in hot weather.

5312.—**Treatment of lawns.**—Wood-ashes are very good for top-dressing lawns. From 1 lb. to 2 lbs. per bushel of phosphates might be added, and the mixture may be used at the rate of 1½ bushels to 2 bushels per square rod.—E. H.

5313.—**Best time for top-dressing.**—Well-decayed manure or peat-ash, with a little soap and dung, may be used for top-dressing. Supplies should be at the rate of 1 lb. to 2 lbs. per square rod.—D. C. R.

FERNS.

A LACE FERN.
GLEICHENIA HICARIA.

Is reply to "R. H." and others, this is one of the most elegant of all the *Gleichenias*, and it may be grown successfully in a warm greenhouse. It has long, branching fronds of a deep-green colour. Good specimens of it sometimes measure from 2 feet to 4 feet in height, and about a yard in diameter. It is a Tasmanian species, and

Fronds of a Lace Fern (*Gleichenia hiearia*).

being a good grower, and one of the best of the section to which it belongs, it well deserves extended culture. It thrives well in a compost of good fibrous peat and coarse sand, stone grit, or well washed road or river sand. Drain the pots well.

5275.—Treatment of Ferns.—Only the fronds that are readily dead or past work ought to be cut off. Otherwise your method of procedure is not far wrong; but it is not well to water them too heavily at first, though if kept in a warm-house this will not matter much. You will also find that in the case of most varieties with clustered crowns, such as the Maiden-hairs, they will do better if divided into quite small pieces, placing them singly in small pots and shifting them on by degrees when established. The soil you name, with the addition of some sand, is right, and after potting they should be placed in a close warm-house or pit, and cleared overhead with the syringe almost daily, but water sparingly at the root until these begin to occupy the fresh soil.—B. C. R.

The herbaceous border in February.—Both during the autumn and early spring there is frequently so much to do that many worthy herbaceous plants do not get the attention at the proper time. So many of our herbaceous favourites are benefited by an annual or biennial division that a few notes may be of use. Unless the operation can be done early in the autumn, so that a few new roots are made before the soil gets cold and wet, it had far better be delayed until the latter part of February or March. I prefer the former time if the season has been fairly mild. *Dolphins*, *Melancholus*, *Daisies*, *Phloxes*, *Monarchs*, *Dianthus spectabilis*, *Doronicums*, *Pyrethrums*, &c., are all much benefited by division and replanting upon fresh soil that has been deeply moved and richly manured. These and many others are very hungry feeders, and cannot be provided with food in a better way than replanting. They also produce better flowers when so treated; but if the operation is delayed too late in spring, a dry time is much against them, and shows its effects more or less all through the summer.—P. U.

TREES AND SHRUBS.

WILLOWS IN WINTER.

SOME of the fairest and most beautiful trees for adorning our gardens whose soil and situation favour their growth are the Willows; but, unfortunately, one rarely sees them. Perhaps they are not adapted for such general planting as many other trees and shrubs that exist in most gardens; but even then, if only planted where they would grow, how many places would gain in beauty, and what a lovely series of pictures would be the result! The meagre assortment of trees and shrubs that we commonly see in gardens, their monotonous repetition at all times and in all places and districts is one of the worst features of gardens at the present day. This is the result of the want of knowledge as to what to plant, for there is no lack of material. The Willow in its summer dress is one of the loveliest of British trees, and nothing in our land is fairer to see than the great White Willows of the riverside; but the Willows I wish to draw attention to here are those which, whilst pretty in summer, are infinitely more so in winter, for some of them have coloured bark, which is brightest in the depth of winter, and glows in the landscape, then producing an effect that simply astonishes all who see it for the first time. Winter is regarded as a

DEAD, SUMMER SEASON in gardens, and so it is when they are filled with poor evergreens to the exclusion of all summer-leaving trees. But some things are most beautiful in winter, and this is certainly true of the Willows here mentioned. Among native or exotic trees and shrubs, excepting the Siberian Dogwood, there is nothing grown in our gardens that can be compared with them. The two very best are the Yellow and Cardinal Willows. The first one, botanically, is called *Salix vitellina*. It is much grown in nurseries, being very tough, and therefore valuable for tying. Its bark is entirely of a yellow colour, which in winter becomes very clear and bright, and a single tree or a group of trees has a charming and most conspicuous effect. It is surpassed in beauty, however, by the

CARDINAL WILLOW. The popular name I give here is that by which the Surrey nurseryman about Woking call it, and some of them grow it largely for tying. I remember one day in January, several years ago, I was in the district of Woking, and saw a wonderful mass of colour in the distance. It was a hed of this Cardinal Willow, with a forest of young shoots, each one of a brilliant red colour, and the effect of the whole was simply indescribable. In these nurseries the stools are cut close every year, but since that time I have planted a fair quantity of this same Willow, and some are now trees 20 feet in height, the prettiest and by far the most interesting trees in the place throughout the winter months. The Cardinal Willow is supposed to be a variety of *S. vitellina*, and bears the varietal name *Britzensis*. Whilst these two are the most brilliant in colour, they are likewise the toughest and most useful in other respects. Their shoots can be tied into knots as tightly as string without breaking. All who have a moist corner, a ditch, stream, or lake, should plant these two Willows in quantity if space permits, and associate with them the Siberian Dogwood (*Cornus sibirica*). In a very short time they will see the absurdity of the practice that some pursue in excluding from the garden the summer-leaving trees. *S. daphnoides* is another pretty kind, and very different from the preceding ones. It has long, slender shoots with bark of a dark-violet colour or almost black, and over this a white mealy coating, the shoots looking as though covered with hoar frost. Yet another kind, the name of which I am not sure of, has this same white substance on the bark. It makes a large tree, with long, straight shoots, and its effect is novel and beautiful. *S. laurifolia*,

THE BAY-LEAVED WILLOW, has rich nut-brown bark, and besides these there are many more that have been recently planted and look most promising. These Willows are a perfect revelation of beauty of a new kind. Everyone is charmed with their splendid effect, and those who see them for the first time are astonished.

5308.—A Privet-hedge.—If the plants were put in this autumn I should advise their being cut down to within 6 inches of the ground-line; but if the hedge has been planted a year the plants ought to be cut down to within 9 inches. By so doing strong, vigorous shoots will be forced from the lower part of the plants, establishing a thorough foundation for a good hedge. If the plants are left at their present length the hedge will always be thin at the bottom. Two or three times during the coming summer the hedge should be clipped to induce a stocky growth to be made.—S. P.

— If I wanted to plant a hedge, no matter for what purpose, the very last thing that I should think of would be the Privet. If the hedge is to be an ornament the Privet must be excluded, for it is one of the least ornamental shrubs that ever came into our gardens. If a strong barrier is required, then again the Privet is useless, for it offers no resistance to any marauder from the size of a cat upwards. To go into nurseries and see the great breaths of Privet and Laurel one would think there was nothing better for our gardens, whereas if we could get rid of these two things those who had planting to do would then have to look about more, and then, perhaps, by accident they would bring into use some of the numerous and pretty things that are beautiful as well as useful. Then, too, there would be more variety instead of the monotonous repetition of two or three things throughout a thousand gardens.—A. H.

— Cut the Privet down to within 1 foot or 15 inches of the ground to make the bottom strong and full.—E. H.

ALLSPICE-BUSHES (CALYCANTHUS).

THESE are American shrubs with handsome flowers of pleasant fragrance. *C. occidentalis* (here figured) grows from 6 feet to 8 feet high, with large mureno-erianum flowers of powerful fragrance. A fine shrub, worthy of cultivation in every garden, it requires ample room to spread. It also does well on a wall. *C.*

Flowering shoot of Western Allspice (*Calycanthus occidentalis*).

floridus is smaller and not so dense, with purplish-red flowers, strongly scented. The names in catalogues, such as *C. glaucus*, *levigatus*, *oblongifolius*, and *macrophyllus* represent forms or varieties of either the eastern or the western species. The two described are hardy, the Carolina species having been grown since 1757, while the Californian has been cultivated over fifty years. Their place in the garden is near a moist and shady walk, not in the open shrubbery, as they flourish best when overshadowed by other trees and where the ground is damp. They grow well near streams and wet places.

SOME OF THE HARDIER PALMS.

CHAMÆROPS.

PALMS are so suggestive of the Tropics that it is generally believed they all require a tropical temperature, and in the case of the greater number this is undoubtedly correct. There are, however, considerable numbers of species whose hardier nature renders them capable of cultivation in an ordinary greenhouse. Nothing gives a plant-house a more striking appearance than Palms, and the ease with which they may be cultivated renders them doubly valuable. The kind here figured is perhaps one of the best known of the many Palms which we possess, though its fitness for greenhouse culture is not generally understood.

CHAMÆROPS HUMILIS is the only Palm that is truly European, the Date Palm (*Phoenix*), so extensively cultivated in Southern Europe, having been introduced from North Africa. Although the specific name of this plant implies dwarfness, it is known to reach a height of from 20 feet to 30 feet, a fact confirmed by the fine specimens of it at Kew and elsewhere. It has been cultivated in this country since the year 1731, when it was grown by Phillip Miller, in the Apothecaries' Garden, at Chelsea. It is one of the few plants which produce offsets from the

base, too, is of a more graceful character than that of that species, and is divided into about forty segments, which are again less deeply split than in *C. humilis*. This description will answer for another supposed species named

C. EXCELSA, which is also a native of China, and to all appearances identical with *C. Fortunei*. The plant sometimes met with under the name of *arborescens* is considered to be only a form of *C. humilis*, and *C. tomentosa* is an Indian species also resembling in its young state *C. humilis*. Other less common species which resemble one or other of the above are *C. Martiana* and *C. Ritchiana*, both Himalayan kinds; *C. elegans*, a very beautiful plant, the young leaves of which are covered with meal-like scales; and *C. hystrix*, the only true member of this genus found in America. It is a native of Georgia, and has a creeping trunk, and spines sometimes 15 inches long.

ORCHIDS.

ODONTOGLOSSUM.

I AM much obliged to "Mrs. Cochrane" for sending me an assortment of *Odontoglossum* flowers, and also I am delighted to find her succeeding so well with their cultivation. The

autumn, and now they are rooting and growing finely, the soil being composed of about equal parts of good fibrous peat and chopped Sphagnum Moss, the pots being well drained. These things, having been well done at the time, will carry the plants along for a twelvemonth, so as to avoid potting in the dry, hot weather.

MATR. BRAYNE.

AERIDES.

I AM requested by "G. P." to tell him a little more about the East Indian Orchids? This I am the more inclined to do because I find from his different letters to me that he has sufficient heat and general accommodation for their management. It is not advisable to restrict amateurs as to what they should grow, because they take such curious whims in their heads. I recently noticed one of these, who had taken *Phalaenopsis* under his wing for a pet; another at the present moment is writing, urging the claims of *Vanda*. Others, again, I have calling upon me for information respecting the cool-house kinds, whilst numbers are devoting their time and attention to Slipper Orchids or *Cypripediums*, all of which indicate most assuredly that the cultivation of Orchids is spreading throughout the length and breadth of the land. In answer to "G. P.'s" requests, I shall commence with noticing some of the most charming kinds in this beautiful family of Orchids. The genus *Aerides* was established by Loureiro upwards of a hundred years ago. They are widely distributed in India, but seldom exceed six or eight years' growth. They are best grown in pots having ample drainage, the only material requisite for surfacing being clean white Sphagnum Moss. They should be kept in a high temperature—that is to say, 80 degs. in the summer-time and 60 degs. in the winter. There should be an abundant supply of moisture in the atmosphere, and with an abundance of fresh air they must not be dry in the winter, but be kept moderately moist. When growing again, about the end of February, the plants will require to have new Moss applied, and to see that the drainage is sound, and good advantage should be taken at this time to cut back the stems at bottom of any plants that have lost their lower leaves. From this time forward more heat and water should be given. The following are a few of the best kinds:—

A. CRISPUM is a beautiful plant, with dull-violet or blackish-purple stems, stout leaves, arranged in a two-ranked fashion, each some 6 inches to 8 inches long, and 2 inches broad. The spike is racemose and many flowered, the blossoms are large and sweet-scented, each being upwards of 2 inches across, waxy-white in colour, tipped with rosy-purple.

A. CRASSIFOLIA is a plant with thickly-set, fleshy leaves, the flowers being rather smaller than the last named, all of a bright rosy-purple. It is a superb plant.

A. FALCATEM.—Pollage of this plant somewhat glaucous on the other side, paler beneath, and some 6 inches and 9 inches long; racemes longer than the leaves; flowers waxy-white, tipped with light-purple.

A. FLEMINGI (the Fox-brush *Aerides*).—This is a stout, robust-growing plant, with a blackish stem; it has flower-spikes, which are branched at the base, some 18 inches long; but I have seen them nearly 30 inches, many flowered; sepals and petals are white, tipped with purple, lips tipped with bright-purple; a superb plant.

A. HOLLERIANI is a grand plant, the sepals and petals, as well as the lip, being of a light tawny yellow, tipped with bright-purple. It is called in French garden A. pictissimum.

A. LAWRENCEANUM is a gigantic and superb form of *A. odoratum*, sepals and petals white, tipped with rich purple. This plant is still somewhat rare, but so beautiful withal it could not be omitted.

A. MACULOSUM.—A very pretty plant. The spikes are a foot or more long, much branched, the flowers are numerous, and of good size. They are white, spotted with rich-purple.

A. ODORATUM.—This is a species first found by Loureiro in Cochin China, and which is still amongst the hardiest of its kind; white flowers, deep-purple lips, which are very fragrant. Amateurs should select plants with the longest racemes of varieties of this species, as there are many forms.

A. QUINQUEVASEM.—A very fine species

Chamærops Fortunei.

base, by which it may be readily propagated. In the South of England it has stood out-of-doors for many years without any protection from frosts other than that afforded by a mat, and has a very distinct and graceful appearance growing amongst other outdoor vegetation. If in tubs it may be placed outside in summer, sinking the tubs below the ground level; in the winter a place in a cool greenhouse may be afforded it. Grown in this way it has a much richer and more graceful appearance than when permitted to stand outside all winter. In pots it also forms a beautiful plant. A light rich loam well drained is the kind of soil in which this plant delights, and for young plants a little leaf-mould may be added; manure-water given now and then will also be found of benefit to it, especially when large. The petioles of this species are clothed with sharp brown spines; the leaf-blade is fan-shaped, rigid in texture, and divided into from twenty to twenty-five deeply-split segments. This species is what is generally known as the Dwarf Fan Palm.

C. FORTUNEI, of which the annexed is a representation, is a native of Northern China, from whence it was introduced into this country by Fortune in 1844. It is quite as hardy as the species just described, from which it may be distinguished by the absence of spines on the petioles, which are slightly serrate. The leaf-

flowers sent do not, however, represent a very fine type, and without wishing to discourage her, I can only say that there is scarcely a really good flower amongst them. Those she calls *O. Alexandrie* are not of the true species, but some natural hybrid forms of *O. Ruckertianum*, *O. Andersonianum*, and other crosses inferior to the type; indeed, they appear to me to be plants that have been selected by an unprincipled dealer, and sold after blossoming as unflowered specimens. This is frequently done, and I advise my readers who may be desirous of obtaining new forms to purchase them first-hand when imported. It may be said why am I so sharp on this matter? Because I am only exposing one of the tricks of the trade. "Mrs. C." seems delighted with her plants, and no doubt they are very acceptable ones, and will provide her with blossoms for a long time; but I think I may safely say that in the course of a year or two she will not look upon such flowers with any degree of favour. The cultivation of the plants appears to be correct, the temperature not being excessive, and the minimum point not too low. I quite agree with "Mrs. C." in keeping the plants in a house with a northern aspect, for this I maintain to be the one best suited for the growth of all cool Orchids. I find "Mrs. C." adopted this advice and repotted her plants in the early

ILLINOIS AT
URBANA-CHAMPAIGN

having bright-green leaves a foot long, and racemes exceeding that; the sepals and petals white, tipped with bright-purple, the lip having an incurved horn and a grand spur the same colour as the sepals and petals.

A. SAVIGIANUM.—A species introduced by Mr. Sander some four or five years ago. The flowers are individually somewhat small, are of a rich crimson-purple, white at the base, freckled with crimson-purple. A very choice variety.

A. SUAVISSIMUM.—This plant somewhat resembles *A. odoratum*; the racemes, however, are considerably longer and flowers more rightly set. The sepals and petals are white, each tipped with lilac; in some forms it bears branching spikes, and is then called *nobile*. A very fragrant plant.

A. VIRENS.—This is a more thickly-set plant than *A. odoratum*, to which it is closely allied. Racemes are longer than the leaves, bearing many flowers, having a white, waxy ground, rich-purple tip.

Many more species and varieties might be added, but the above dozen will be sufficient for "C. P." to make a start with; but he can have descriptions of more should he want them when he has established these. Some of the rarer kinds are purposely omitted.

MATT. BRAMBLE.

THE ELEPHANT'S TRUNK PHALANOPSIS (P. LOWI).

This *Phalanopsis* is certainly a very beautiful species, but yet it has not the purity or brilliancy of some others—for instance, such as *P. Aphrodite*, *P. granuliformis*, &c. It has, however, been one of the *Orchids* which I have always failed in managing, seven being the highest number of flowers I have got upon a scape; but I have seen fifteen blossoms on one spike, and when in this condition it is charming. It was generally in its deciduous state that I experienced the most difficulty, but it was from the error in making the resting season too long, and in keeping the temperature too high, that I think was the cause of my failure. Now I have ascertained that two months are quite long enough to keep them under the dry system. *P. Lowi* is a species that delights to be grown in pure limestone rock-land, and upon this I would recommend it to be placed in preference, as they seldom thrive in any other material. When in first-rate order this plant is exceedingly beautiful with its white flowers, which are suffused with violet. It also has a strange rostrum, from which it takes its vernacular name. I would have given the names of a few others which would thrive well under the same treatment, but I must delay them until another time.

MATT. BRAMBLE.

THE KITCHEN GARDEN.

GOOD SAVOYS.

Savoys are most valuable late autumn and winter vegetables, and if given generous treatment—like other Cabbages—will repay for the trouble. The following are excellent kinds: The Dwarf Early Green-curler (Fig. 1) is one of the

Fig. 1.—Dwarf Early Green-curler Savoy.

best for a general crop, forming, as it does, close, compact heads. The Long-headed Savoy (Fig. 2) is an excellent moderately early variety, of good quality, and it yields a large crop on a small space of ground, as on account of its upright, compact habit of growth the rows of it can be planted rather close together. It also possesses the good property of heading in well in the latter end of the autumn, so that it can be sown to advantage rather late in the season. The Drumhead is a large-growing sort, of good

quality, suitable for large gardens. The Gohlen Globe is a good, useful, yellow-hearted kind, hardy in constitution. Early Dwarf Um is the best dwarf variety. Its flavour is good, and it is very hardy, standing even severe frosts well. Tom Thumb, a small variety, is also crisp and good, and very hardy.

5293. — **Parsnips for show.**—This vegetable requires a deeply-moist soil, so that the root can penetrate easily 2 feet deep. If the soil is not deeply dug and not well broken up, or mixed with large stones, the Parsnips, instead of having one long straight root, will have a number of smaller ones which spoils them for exhibition, of course. The ground ought to be trenched 2 feet deep in the autumn, which allows time for the soil to settle down into its place before the seed is sown early in February following. Before sowing the seed, however, the soil should be forked over a good depth, breaking up any rough parts. Instead of sowing the seed in drills in the ordinary manner, make holes with an iron bar 2 feet deep, filling up the hole with prepared compost, decayed vegetable refuse, wood-ashes, sand, and old potting compost, well mixed together and sifted. These holes, made 15 inches apart in the rows, the rows 18 inches wide, will allow plenty of space for the leaves to develop fully. Sow three or four seeds in each hole, covering them lightly with a little of the compost. When the plants are large enough to handle, pull all out but the strongest. Student and Hollow Crown are the best sorts to grow.—S. P.

5324. — **Fixing hot water pipes.**—I should advise you to fix one row of pipes close against the front of house—near the eaves—and the return along the path, say 2 feet from the flow. Plant one row of Tomatoes between the pipes, and two more at the back; this is all there is room for. Or you might fix the flow and return pipes one over the other close along the front, and the plants behind, with equally good results.—B. C. R.

— In a house only 5 feet wide, the proper place for the hot-water pipes is close to the front wall. Your first row of Tomatoes may then be 1 foot from the wall. Your proposed arrangements of the rows of plants do not, however, appear to me to be right, as the height of the house in front is only 2 feet 6 inches. You had better fix some wires to the roof 8 inches apart, and 1 foot from the glass, and have one row of plants along the front to be trained to wires. You will then be able to attend to the plants with comfort, and if you set out 1 foot apart, and train them to a single stem, the one row will fill up the space on the wires. You may, however, try a row of plants on the back wall. They will be all right for a good part of the season if you do not allow those on the wires to shade them too much. You may depend upon it, if you crowd the house with the number of plants proposed, that you will make a mistake.—J. C. C.

Gloxinias.—These are not so generally grown by amateurs as they deserve, more especially now that a good strain of seed will produce plants of infinitely better quality than those formerly secured in this way. The *Gloxinia* is one of the plants which the hybridiser has taken in hand with remarkable success, and as the seedlings are more healthy in growth and less liable to disease than any propagated in other ways, I would strongly advise one or two of my amateur friends to go shares in a small packet of some reliable strain. Leaf-soil and sand in equal proportions, and only a small layer of this over a well-drained and rough compost will answer very well. Sow thinly, and do not cover the seed. In a former note I gave directions for sowing seeds under glass, and they apply to *Gloxinias* equally with other subjects. Sow in February, and prick off into thumb-pots in May. Never let the seedlings be checked and grow as near to the glass as possible. A moist stove heat during the earlier stages, followed by that of a warm greenhouse later on, with plenty of light and water, will generally be successful in raising good plants. Good drainage, and a compost of turfy loam, leaf-soil, and sand, with a dash of sharp sand, should always be accorded them as soon as the seedlings

pots are full of roots. It is also much best to place them into their flowering-pots direct from the small ones, the leaves being easily injured and retaining any dirt which may come into contact with them. They have a more or less tendency to recurve over the sides of their pots, and this renders future shiftings difficult. *Gloxinias* enjoy a generous treatment, and will benefit from liquid-manure when the pots are full of roots, but care must be taken that it

Fig. 2.—Long-headed Savoy. (See Article "Good Savoys.")

does not touch the foliage, or their woody character will cause them to remain disfigured.—P. U.

OUTDOOR PLANTS.

5316. — **Plants for a bed.**—Judging from the reference to turf in the inquiry, I gather that this is growing on the site for the lairder, or has been. This should be dug in, but not too deeply; if more than 1 foot from the surface the roots will fail to reach it before it has decayed, and therefore would be lost. It is always a good plan to trench the soil 18 inches deep before planting herbaceous subjects. No time should be lost in doing this, to allow time for the soil to settle down into its place before planting is done early in March. With the exception of burying the turf as suggested, the surface-soil ought to be kept in the same position, leaving that from the bottom in the same place, but thoroughly breaking it up to admit of a free percolation of the water from heavy rains. If the plants are put in angle-wise four rows can be accommodated. The back row planted at 3 feet 6 inches from the front will admit of the others coming in very well. Allowing on an average of 3 feet from centre to centre of the plants in the back row, seventeen will be required. The following will be found suitable. I append the height which each grows, varying, of course, according to circumstances. *Helianthus communis*, *Soleil d'Or*, 5 feet, *H. multiflorus*, 7 feet, *Bocconia cordata*, 6 feet, *Chrysanthemum latifolium*, 4 feet, *Achillea millefolium roseum*, 3 feet, *Pyrethrum uliginosum*, 6 feet, *Delphinium*, one double and one single, 4 feet each. *Phlox herbaceous* type, at least two sorts, 4 feet, *Spiraea Aruncus*, 4 feet, *Spiraea venusta*, 4 feet, *Double Peony*, albiflora, *Mono. Vilmorini*, 3 feet, *Lychnis chalcidionica*, 3 feet, *Tritoma glaucescens*, 3 feet, *Aster Nova-Anglie* (deep-rod), 3 feet, *Novi-Belgi elegantissimus*, 3 feet. For the rows in front the following is a good selection: *Alyssum saxatile*, 1 foot, *Anemone fulgens*, 6 inches, *A. japonica alba*, 2 feet, *Aubrietia Campbelli*, 4 inches, *Burkholderia salicifolia*, 2 feet, *Campanula persicifolia alba*, 1 foot 6 inches, *C. p.*, 2 feet, *C. murralis alba*, 1 inch, *Carnations*, *Dianthus chinensis hybridus*, 1 foot, *Erigeron aurantiacum*, 9 inches, *Lychnis viscaria splendens*, 1 foot, *Gaillardia grandiflora*, 1 foot, *Helenium autumnale*, 2 feet, *H. pumilum*, 1 foot, *Heuchera sanguinea*, 1 foot, *Iris pallida*, 2 feet, *Chrysanthemum maximum*, 1 foot, *Monarda purpurea*, 1 foot 6 inches, *Orolon vernus*, 1 foot, *Rumbeckia Newmani*, 1 foot, *Spiraea astilboides*, 2 feet, *Zauschneria californica*, 1 foot, *Trollius europaeus*, 2 feet, and *Tiarella cordifolia*, 9 inches.—S. P.

— You should have the following: The best self-coloured *Carnations*, not forgetting the *Ch. King of the South*, and the white variety *Gloire de Nancy*, which will give plenty of bloom in June. *Chrysanthemum* of the *Plum* class, and plentiful in June,

such varieties in particular as Mrs. Sinkins, a large, fine white kind, very free, but too apt, unfortunately, to burst the calyx. For June and July also Lilies, *L. candidum*, followed by *L. auratum*, the Tiger Lilies, and varieties of *L. speciosum* in autumn. *L. speciosum album* is a very beautiful flower, and of purest white. Delphiniums for summer and the lilies will give a splendid lot of cut bloom, the German kinds in particular. Queen of May (rose-lilac, the falls veined with yellow), Anrea (golden-yellow), Celeste (lavender), Florentino (nearly white, free, and sweetly-scented), Gazello (lavender, with the standards marked with white), More. Cherean (white, the standards and falls edged with violet), Ialmatica (lurmler), Rigidetto (golden-yellow), and Victoria (white, with blotches of purple-blue). These are the finest for colour. You could also have a few Spanish and English Irises, bulbous kinds, which have very fine flowers, displaying considerable range of colours. The Tuffed Pansies in variety will prove helpful, and an edging might be formed of them to the bed. There are many varieties, the flowers ranging from purest white to almost black. Pyrethrums for early summer, particularly the single and double whites. Scabious, Blue Carnation, Stocks, Zinnias, very fine in the autumn, Daffodils for the spring, the White Pines Narcissus, and double variety blooming in May; Campanulas, *C. persicifolia* alba, Canterbury Bells; Chrysanthemums in September, especially Mima. Desgrange and its sports; Dahlias in variety, Perennial Sunflowers for autumn, Michelons Daisies for the same season, Gaillardias, Everlasting Flowers, Christmas Roses for winter, besides other things; but you have quite sufficient for the bed, and they will give plenty of bloom from early summer until the frosts occur.—C. T.

5324. —**Making a flower garden.**—It appears to me that you are going to a lot of unnecessary expense in trenching up the ground in the way stated, except where there are to be flower-beds or shrubberies. You would have done better if you had sought the advice of a landscape gardener and got him to have given you a plan of the ground to lay out in the way you would like it best. You would then have seen at a glance where to trench and where not, as the space that is to be devoted to lawns certainly does not want trenching. Nor is it necessary to wait until next autumn before you begin forming the flower garden. If you decide to do the work without any further help than your present advisers, mark out the walks in the first place; then do the same with the borders for shrubs and trees, and decide on the number and size of the beds for flowers. For the two latter you may trench the ground, but except to bury the turf I fear that you must not bring the bottom soil to the top, but after stirring it up leave it in the bottom of the trench. With regard to the walks, the top soil, after the turf is removed, may be used to the depth of 6 inches for other purposes. Do not be persuaded to trench up the remaining space. Take off the turf to the depth of 3 inches, and convert it into ashes by making a slow fire; then dig over the ground an ordinary spit deep at once. Early in March fork over the space again, and then spread on the surface the ashes from the turf. Another light forking over to mix the ashes with the soil early in April, and a roller run over the ground a few days after when the surface is dry, and you will have a capital bed for the reception of Grass-seeds to form your lawn, and at the same time keep all your good soil near the surface to benefit the Grass, whereas in ordinary trenching you bury the good earth and bring the inferior to the surface.—J. C. C.

—It is rather difficult to see what can be gained by sowing the land with Oats and Grass if it is truly infested with weeds, for these crops will neither charm the weeds away nor destroy them. The right thing to do is to clean the land, and as mowing the crops will prevent this the proposed plan would hinder operations. I should take advantage of spring and summer to clean the ground thoroughly. The weeds may then be materially reduced, and all the worst of them got rid of by early autumn. The ground would also be in good order for the carrying out of the permanent plan. The luras could be made in the autumn. If the Grass is to be sown, this should be done about the last week in August or the first week in September, and then the

young Grass will make a little growth before winter, and soon make a good turf the following spring. If all the land has been treed up, that to form the lawns should be well rolled and trodden previous to sowing, or there will be unequal settlement, and a lawn not at all fit for tennis. The flowers-beds, and borders, too, could all be prepared during summer, and they, too, would then be ready for planting in autumn. I think I have said enough to make it clear to "A. C. J." that by taking a crop he is only hindering operations and depriving himself of the opportunity of doing the work thoroughly at the most favourable time and in the best way.—A. H.

THE ASIATIC RANUNCULUS (R. ASIATICUS).

This beautiful old plant produces neat, dressy double flowers of almost every colour of the rainbow. Its innumerable varieties are divided into sections, such as the Dutch, Scotch, Persian, and Turkish, each representing a distinct race, but all beautiful, and well deserving any amount of care and attention, for they look well anywhere or in any position, but are best where they can be seen in bold masses. The culture of this *Ranunculus*, though usually considered somewhat difficult, is simple enough if a few essential particulars are observed. The situation should be open, but not exposed, and the soil a good loam, thoroughly mixed with

Asiatic Ranunculus.

decayed stable manure, equal to a third of its bulk. About a month previous to planting, the bed should be prepared to a depth of 15 inches, and planting should take place in about the last half of February, but in some seasons it may take place in October, though such an early date is not advisable. Drills about 6 inches apart and 1½ inches deep should be made with a small hoe; the claws of the roots should be placed downwards, and be firmly pressed into the soil, which should be raked over the roots, and a top-dressing of about 2 inches of good loam given. If the soil is very light it may be gently luted down with a spade in order to obtain a firm surface, and this may be repeated just before the foliage appears, say about a month or six weeks after planting. As this *Ranunculus* delights in moist soil, water should be plentifully supplied if there is a scarcity of rain, and in no case should the roots be allowed to become very dry. A light top-dressing of artificial manure or guano just as the foliage is developed will be beneficial. When the flowers are past and the leaves have faded away, the roots must be taken up and dried and stored in a cool place in sand till the next planting season, for roots left in the ground are often injured by rains and are never strong. The Persian varieties are the finest as regards colour, compactness, and symmetry of growth; but the Turkish varieties are of hardier constitution and of freer growth than the edged and spotted kinds, and therefore are better suited for beds, lawns, and masses. The Scotch and Dutch

varieties are also fine for masses in beds being all of highly effective colours. It is useless to enumerate the different varieties, as they are usually sold according to colour and are mentioned in nearly every bulb catalogue. The large semi-double French (de Caen), and the Italian forms of this plant are good additions. G.

TUBEROUS BEGONIAS IN DISTINCT BEDS.

EACH year the Tuberos Begonia advances in favour, and it is a common practice to have distinct beds of the plants one colour, or shades of one colour, to each bed. This is commendable, as new effect is gained. Of course, one does not require too many beds of this character, otherwise the aspect of the garden will be garish and uninteresting. I noticed last year in the London parks, and also some of the parks in the North of England, that the Tuberos Begonia was planted in this way, in one instance the bed being composed of a pure white variety, set off by an edging of *Dactylis glomerata variegata*, a very charming, because graceful, plant to associate with the Begonia. This plan is rendered easier now that seed of Tuberos Begonias in selected colours can be raised true to those colours. During the past few years the Tuberos Begonia has undergone a great change, and its usefulness for bedding-out increases each year. The plant is now of dwarf, compact habit, the leaves almost resting on the soil, sturdy, and without the scraggy aspect of the older types, whilst in the form and colour of the flowers we can see the same advance, the flowers being broad and very pale in the case of the double kinds, the colours ranging from purest white to intense shades of orange. The Tuberos Begonia is finer for bedding than the fibrous-rooted types, but we may mention that Princess Beatrice is a gem for edging, the small pink and white flowers appearing in profusion and almost hiding the leafage from view. This is the season for raising Tuberos Begonias from seed, and in all gardens where effective colouring is desired in the summer months good use should be made of this flower. Get a good strain of seed, in which the colours are decided, the form and size of the flowers all that can be desired, also the habit of the plant. They succeed better in cool, moist seasons than when the weather remains hot for weeks, as in the year 1887, but it is not often that they fail absolutely, which is more than can be said for the Zonal Pelargonium. A moderately light soil, inclined to be peaty, is the best, and during the summer give the beds liberal waterings if the soil is dry. At Haddon, Lord Rothschild's residence, the Tuberos Begonia is used by the thousands, and produces rich pictures of strong colour, not so garish and formal as in the case of the Pelargonium or carpet plants. G.

Callas.—Whilst there seem to be differences of opinion as to whether it is wisest to plant out Callas in the spring for the making of good summer growth, or to retain the plants in pots, I find very many growers adopt the plan of keeping all their stoutest ones in pots, only turning them out at the proper season, removing into shoots, rubbing down the balls of soil, and potting in as small ones as well can be at the first, keeping them in the pots all the summer, and pushing them along by housing early for the production of early flowers. In many cases a further shift into rather larger pots becomes needful during the summer. The market growers regard this as the best course where Callas have to be forced. That the weaker or smaller stems or offshoots when planted out into highly manured ground do relatively make the strongest growth there can be no doubt, but as these, even if the stems and leafage have become ever so stout, still being newly potted in the autumn are less fitted to stand early forcing than are those which have been kept in the pots all the season. It is very important, however, especially seeing that Callas are of a semi-aquatic nature, that very ample waterings be given, especially to pot plants, and also that the pots stand on a bed of ashes or Cocoa-nut-fibre refuse. Liquid-manures are of more service to pot plants where the roots are densely packed than to plants outdoors, where because of ample manure and root room the chief want is not water but plenty of moisture.—A.

LILIUM AURATUM.

There is nothing in the way of bulbs with which I have had to deal which has disappointed me more than Liliun auratum. I grew it first in pots, and on the whole this system has given the greatest satisfaction, as the bulbs have lived longer than when planted in the open. I think they would have lasted still longer if I had used greater care in preventing bright sun from reaching the foliage when it was quite young. The leaves may perhaps bear the full force of the sun when they are growing in the open air, but it is very different when it reaches them through the glass, and they are at the same time surrounded with a hot and dry atmosphere. It has been after passing through such an ordeal that I have found the leaves more or less scorched, and ultimately turn black. This last condition would make them susceptible to attacks of insects or fungoid growth, to which some people fancy they can trace the cause of failure; but I think the presence of insects or fungoid growth on the injured leaves is the effect and not the cause. The longest time I have kept a bulb of this Lily in a satisfactory condition was six years. This was one that was very promising the first year. It sent up a strong stem, which was well studded with leaves and showed seven flower-buds. These I reduced to one as soon as the buds could be seen. The reduction of the number of flowers had a greater effect on the diameter of the growth than I anticipated, as this plant was conspicuous amongst the others for its stately stem and large and handsome leaves; but, strange to say, the one flower left came deformed. The next and three following years the bulb so treated was in every way far more satisfactory than the others. It is about eleven years since I planted the first lot of bulbs in a bed amongst Rhododendrons, but they all disappeared in about four years, and the same thing occurred with others planted in a well-prepared soil in a mixed flower border. Five years ago, when I made a new garden, I started growing this Lily again in the open air, this time with English-grown bulbs, which came to hand apparently full of life and vigour. They, too, have disappeared, and that in a garden where everything else thrives in the most satisfactory manner. I certainly hope for better things when I grow bulbs in a maiden soil.

J.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton Street, Covent Garden, London. Letters on business should be sent to the Publishers. The name and address of the writer are required in addition to any designation he may desire to be used in the paper. Where more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, rules, and menus vary so infinitely that several answers in the same question may often be very useful, and those who reply should do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

- 5311.—Wireworms.—Will someone kindly tell me what are wireworms?—ALFIA.
5312.—Gloxinias from seed.—Will someone kindly inform me how to raise Gloxinias from seed?—S. D.
5313.—Heaths after flowering.—I should be glad to know how to treat heaths that have done flowering?—J. H.
5314.—Preserving Green Peas.—Will someone kindly give a good recipe for preserving Green Peas for winter use?—ELMACARON.
5315.—Striking cuttings of Golden Elder.—What is the best time to strike cuttings of Golden Elder in the open ground?—BALMACRIBB.
5316.—Treatment of Chinese Primulas.—Will someone kindly inform me as to treatment of Chinese Primulas, and the best time for sowing the seed?—J. H.
5317.—Early Lily of the Valley.—Will someone kindly tell me how I can best get Lily of the Valley to flower early? I have a frame, but no hot-house.—T. HARRIS.
5318.—Lucilla gretselma.—Will someone kindly inform me the best means for striking cuttings of Lucilla gretselma? I have tried to do so, but have failed.—J. M.

- 5340.—Best Lilies.—Will someone kindly tell me the names of some of the best Lilies (white preferred) for outdoor cultivation, the times to plant, and the months they bloom in?—W. R. L.
5350.—Making a Tomato-house.—I have some garden frames which I want to make into a lean-to house for Tomatoes. 1. What height must it be? 2. What width from the wall?—H. B.
5351.—Ashes for the garden.—I have a receipt made under my fireplace for use for the dust, or ash, or fish from the fire. Can I use them to advantage for the garden, and if so, how?—JIMIE PARKER.
5352.—Using Pigeon-manure.—I have some Pigeon-manure. Will someone kindly tell me how I can use it to the best advantage? Can I use it for vegetables, and if so, what kinds?—H. H.
5353.—Aspidistras in pots.—I have some Aspidistras in pots, which are crammed full of roots. The new leaves are a smaller size than last year's. Is it that they have not enough room to grow?—H. S.
5354.—Tomatoes under glass.—Will someone kindly tell me the name of the best Tomato for growing under glass for market? Also the name of any book on Tomato-growing for the market?—S. H.
5355.—Salt for an Asparagus-bed.—Will someone kindly inform me what quantity of salt is required per yard for an Asparagus-bed, and which is the best time to apply it?—F. HENRY, Surrey.
5356.—China Asters, &c., from seed.—Will someone kindly tell me if China Asters and African and French Marigolds can be raised from seed in a cold frame to make good results, and when to sow?—HARRO of TORKIN.
5357.—Ferns for a bank.—Will someone kindly tell me what Ferns would best grow on a bank at the bottom of the garden? Some of our neighbours' trees are overhanging it, but it gets the sun in the afternoon.—J. M. R.
5358.—Flowers for Christmas.—What flowers are there I could have in blossom next Christmas (with preference), either in the open or under glass? A few brief hints as to mode of cultivation would much oblige.—J. F. H.
5359.—Tomatoes in boxes.—What would be the best size to have boxes for Tomatoes under glass? Please give depth, width, and length? Would it be best to have one plant only in each box, or boxes large enough to hold several?—J. F. P.
5360.—Plants for a greenhouse.—I should be much obliged if anyone would give me some advice as to how to fill a greenhouse (also 15 feet by 7 feet) with plants that would not require much skill to manage?—AN AMERICAN, Stamford, Virginia.
5361.—White Cluster Rose.—What is the name of the White Cluster Rose so often seen in the country, both as a climber up the front of cottages, and as a standard, with small, pointed, dark green, very glossy leaves, and a sweet almost scent?—M. H. W.
5362.—Drooping plants.—What are the names of two or three good drooping Fuchsias and trailing Begonias for hanging-baskets? Also any other plants that will hang down and cover a basket (not Campanula or Mother of Thyme)?—M. H. W.
5363.—Rooting cuttings of fruit-trees.—Will "J. C. C." or "J. H. E." kindly give me a few hints on this, especially Cherries, including Governor Wood, Baronne Preost, Annetta, May Drake, Knight's Black, also Apple and Pear-cuttings?—SEASIDE, ENGLAND.
5364.—Tomatoes in a greenhouse.—If I sow Tomatoes at end of the month, would it be possible to keep my "Geraniums" and other half-hardy annuals in the same greenhouse until bedding-out time? If so, which would be the best way to manage?—J. F. P.
5365.—Yield of Tomatoes.—What is the average yield of perfection and Ham Green Favourite Tomatoes under good cultivation in a greenhouse? When would plants (sown end of January) commence fruiting, and how long would they continue fruiting?—J. F. P.
5366.—Manures for Cinerarias and Calceolarias.—Would someone give me the names of good manures for Cinerarias and Herbaceous Calceolarias? Perhaps "H. C. E." would kindly help me in this matter, as I have some fair plants and should like them to flower well.—I. T.
5367.—Length of a Tomato plant.—What is the average length of a Tomato-plant (perfection and Ham Green Favourite) in a greenhouse (6 feet high open-roof), would it be best to grow them in pots or boxes raised 6 inches off the floor, or on shelves like "Geraniums," &c., and?—J. F. P.
5368.—Wire-netting for Peas, &c.—Will an experienced cultivator of Peas who uses wire-netting kindly give myself and other readers an account of his work? Does he find any trouble with (a) Garden Peas or (b) Sweet Peas? Is a double row preferable to a single one?—A. D. M.
5369.—Tea Rose cuttings.—Last October I had a few Tea Rose plants and cut up a few broken shoots and stuck them in round the edge of a large pot. Some of them have rooted and are growing. Should I leave them where they are, or pot them off into small pots of good soil now?—RINDROSS.
5370.—Corrugated iron for stages.—In a recent issue of GARDENING corrugated iron was recommended as covering or shading over hot-water pipes to be used with hot lime-wash. Should both sides of the iron be covered, or only the one next the pipes, and should the time be freshly glazed?—ENGLISHMAN.
5371.—Clematites.—Will "P. H." kindly tell me if any of the Clematites mentioned in GARDENING, January 13, have only four petals, as I do not wish to get any crested varieties? Can I raise them from seed, and where can I get it with the various orders kept separate?—C. J. H., Market Harborough.
5372.—Ferns for a case.—I have a glass-case and wish to know what would be the most suitable Ferns for it? It is in a room in which a fire is burnt daily in a gas-lamp house. I have a upper frame, movable for the sun, and a lower frame for the sun, and should give other hints would oblige.—A. D. C., GARDENING.

- 5373.—Moss on a tennis-lawn.—Will some practical person kindly tell me how to get rid of Moss on a tennis-lawn? It has been raked off and leaf-mould has been spread over it and seed sown, but the following year it is not had as ever. The soil is very sandy and light, so that lime makes it very hot.—S. S.
5374.—Cutting back Rhododendrons.—Will someone kindly tell me the proper time to cut back Rhododendrons? I have some 7 feet and 8 feet high, and I want to cut them down to within about 3 feet of the ground. If I cut them down next month will they shoot again the same as the common Laurel?—T. LLOYD.
5375.—Raising plants from seed.—Will the following plants raised from seeds I sown now come to perfection this summer, or, if not, when should they have been sown?—Phlox Trimmoulli, Scabiosa, Grains, Mikato Poppy, Sunflower, Antirrhinum, Clarkia, Coreopsis, Eschscholtzia, and Verbena?—M. G. W.
5376.—Climbing flowering plants.—I should be extremely obliged to "J. C. C." or "H. C. E." if they would tell me what kinds of climbing flowering plants would grow in a hopper back west, and that gets no sun till noon? I want them to grow up my house window, and plants that do not die down every year.—G. H.
5377.—Tuberous-rooted Begonias.—I have some bulbs of these Begonias, and would like very much to increase them by division in the roots. Can I cut the tubers in two like Potatoes, and let it best done before or after starting them? Also, will it weaken the flowering in any way, as I want to have some good flowers?—KENT.
5378.—Datura cornucopia.—Will anyone kindly tell me if the new American plant Datura cornucopia is a delicate one, and requires heat during the winter? I have had some plants which flowered well this summer, and they were housed in the end of September, but killed off in November, and are seemingly dead to the roots.—VERA.
5379.—Heating a vinery, &c.—Would someone kindly inform me—1. When would be the best time to heat a vinery by propagating-houses by means of a boiler and hot-water pipes or by stoves? 2. If there are, say, three houses to be heated, I presume it is more economical to have them all heated by one fire, if possible. Locality Isle of Man?—STRELLIANA.
5380.—Rhododendron dropping their buds.—Will someone kindly tell me the cause of sweet-scented Rhododendrons dropping their buds? I have five plants rather large and one small one. The large plants have lost the majority of buds, while the small one is all right, the buds swelling nicely. The buds go black and rotten inside while the outside appears to be all right.—G. T.
5381.—Flower farm in the Riviera.—Which part of the Italian Riviera between Ventimiglia and Leghorn is most suited for a flower farm? Does it require a large sum of money to begin with, and about how much? Which would be the best market for the sale of the produce? Could a practical man undertake the heavy work by obtaining by advertising in GARDENING?—G. M.
5382.—Heating a sitting-room.—I am desirous of obtaining a heating apparatus suitable for a sitting-room 13 feet square, 11 feet high, in order to protect my plants, which are in the bay window, from frost. Will some kind reader say a good apparatus, either oil, or coal, or coke? Someone's experience on this matter would be most welcome. Many of your readers, it is I am sure, much needed just now.—A. SANDERS.
5383.—Good blue annuals, &c.—Will someone kindly give me the names of some good blue annuals, which will bloom well during the summer? I wish to fill in a border at the back of which there are dwarf Roses, so require some flower in front which will not grow too high. I thought of a carpet of white Nasturtiums with some taller blue flower, but any suggestions would be gratefully received. Also if the White Nasturtium is as good a bloomer as the ordinary red? The border is about 34 feet wide in front of the Roses.—FAVY FAY.
5384.—Pruning Vines.—I have in my vinery some old Black Hamburghs growing for a number of years, and pruned on the spur system. These spurs are nearly 1 foot in length (from the main rod) from cutting them back every year to 1 inch or 2 inches. I have been told by a friend of mine to cut these old spurs all away clean into the leader, and that they will break out again and bear on the young shoots this year. I would be much obliged to any person that would kindly let me know if this would be a good course to pursue?—KENT.
5385.—Treatment of Carnations.—I have about 150 last year's layers of Carnations, chiefly Malmaisons, in small pots, now in a cold frame. When should they be repotted, into what sized pots, and also best compost for same? I have some "market" pots 4 inches. Are these large enough? After repotting I purpose standing them in an unheated span-roofed Rose-house. Will this be the best? Last year my plants did very badly. Many of the buds failed to open, others were very small. I thought this was caused by harbing them in pots too large for them—6 inches. Shall be glad of any information re above, and any hints for after treatment will be welcome? I am much obliged to "J. C. C." and "P. H." for their instructions re Roses.—H. S. H. C., Birmingham.
5386.—Window-houses.—I wish to have boxes made to fit on to five windows, with stone ledges, in front of my house at Aylescombe. The situation is north-east. What is the best material to use, and what should be done to ensure proper drainage without danger of drought? What breadth and depth should they be, and what ought to be the soil, allowing about 12 inches for each box? With what sort of soil should they be filled, and what would be the best kinds of plants to purchase to obtain a constant supply of bloom from spring till late autumn? What kinds of creepers would look well either in climb up the sides of windows or hang them from the front of boxes? And should separate boxes be made to fit on front and side of two windows, or would a continuous box be better?—H. OSBORNE.
5387.—Plants in Rhododendron beds.—I am much obliged to "J. C. C." and others for their kind replies to the above query of mine (see GARDENING, December 23rd, page 561). I should be further obliged to any of your kind readers who could give me any hints what would make a good compost for the peat beds to grow

with the filices. World Lobelia, Golden Feather, Pansies, Crassulium tomentosum, or any of these hardy low-growing plants do in the west? I want to furnish up the beds as they look so bare. The beds are 10 feet by 10 feet and 2 feet deep, a Rhododendron 1 foot high planted in the centre of each in a good open aspect. I would also like to know if the *Glaucium leucocorymbium* will grow in the peat as well as the *garlyonias* mentioned by "J. C. C." A definite answer will be highly esteemed by—K.R.T.

5388.—Name of a bulb.—I shall feel greatly obliged if anyone will kindly tell me what is likely to be the name of the bulb which I must have received by mistake with some others from England a few years ago. When grown it had long narrow leaves somewhat like a Narcissus. The flowers were pendulous, like yellow stars, and reflected when open, the outside and buds a deep orange, almost red, the flowers about the size of a shilling, and there were black spots somewhere, but I cannot remember whether on flowers or leaves. It was raised in a slightly heated frame and flowered in June. The nearest approach I can find to it in any catalogue is *Tritonia aurea*, but this is given as *Crocus aurea*, which is said to be the same as *Montbretia crocosmeiflora*, which I have grown, but it is not the kind of plant I had before.—M. B., *Helenburgh*.

5389.—Growing *Dianthus*.—Will anyone be good enough to tell me the best way to grow *Dianthus*? I am most anxious to grow my grand, but they seem most difficult and troublesome to grow. The year before last I sowed them in a shady border in August or September, but nearly all of them died away. The few that were left bloomed very well. I took seeds from them, which have not come up. Then I got some seeds from one of the best seedmen in England, and sowed them in a box, putting them in a sunny gallery in the house, as I have no heated greenhouse. They came up, but now they seem to grow very long and thin, and then die off. Who can I do? Shall I put them in little pots? They are 2 inches high, and 4 inches long. If I sow some out-of-doors in March or April, will they flower this year, or could I get plants of *Dianthus*?—C. M.

5390.—Evergreen hedges.—Two or three weeks ago there was an interesting paper in *GARDENING* on "Evergreen hedges for shelter," either by "J. C. C." or "J. Groom, Gosport," both of whose articles I always read with great interest. I should be grateful for instruction on one point—viz., when to plant laurels (common and Portugal), *Cypripedium leucanthemum*, and *Hollies*? Should the latter especially be planted in April or May, and not in autumn? I have a large kitchen garden, sloping south, east and west, and much about the year, with the south-west winds which prevail on this coast (near Westmouth). It is surrounded by a high Thorn hedge, getting thin at the bottom, and I want to plant evergreens inside to thicken it without cutting down the Thorn hedge. How near may they be planted? *Hollies* are hardy here, but very slow growing, as it is apt to be very dry in summer.—M. T. S.

5391.—Construction of a propagator.—I am about to make a propagator, heated with a paraffin lamp, and build pretty much as follows. Body boxed in close and made of l-inch match-boarding. Tin pan for water, 2 inches deep, over which is a plate of corrugated galvanised iron, punched full of holes. Cocoa-nut fibre refuse on top. Pots of cuttings, &c., in this, and a glazed and hinged lid lined with the top of boxing and sloped flesh facing. A small sliding door at one end to put the lamp in and out. What height should the tin pan be off the top of the lamp chimney? Should there be a tin chimney constructed to carry the draught up by the end of the propagator opposite to that at which I introduce the lamp, or will there be enough draught by letting the heat (and presumably the fumes too), ascend up between the sides of the box and the edges of the tin pan, and so through the perforations and into the Cocoa-nut-fibre? I want to start seeds, cuttings, &c., for spring.—T. H. BROWN, *Stour*.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5392.—Standon's Manure.—Mrs. Watson should look into the advertising columns, where she will find all she requires to know.—J. J.

5393.—*Cypripedium insigne* (*Guernsey Correspondent*).—Pot in about equal parts of peat and loam and chopped sphagnum, adding a little sand.—M. B.

5394.—*Ansellia africana* (*T. J.*).—The flower sent under this name appears to me to come near to the plant known now as *Ansellia confusa*, which is of a lighter yellow, smaller flowers, and is not nearly so brittle as the typical plant.—M. B.

5395.—*Pholidota imbricata* (*T. J.*).—This is a plant I used to grow with the greatest ease potted in Sphagnum Moss, mixed with a little peat, and given a large amount of heat. I do not, however, think it is worth the trouble.—M. B.

5396.—*Cymbidium Lowianum* (*Mandianum* (*C. J.*)).—This is a rare plant and should be well taken care of. The flowers are of a buff-yellow, with the lip a tawny yellow. It requires the same treatment as the typical plant. There is much controversy about the beauty of this Orchid.—M. B.

5397.—Orchids in a drawing-room (*Mrs. W.*).—I do not think you will succeed in growing any of the six Orchids mentioned in the drawing-room, neither do I think you would find much better success with them in a cool greenhouse, but you might manage *Cypripedium insigne*.—M. B.

5398.—*Moorea irrorata*.—*J. B.* asks for information respecting this plant; but the truth to tell, no one knows very little about it, it having been imported a few years since from Peru. The flowers are produced upon an upright spike and are reddish-brown in colour, with a pale centre, and it is named in honour of Mr. Moore of Dublin.—M. B.

5399.—Plant questions (*T. Eastlake*).—I really cannot comply with your requests, for your questions would make a perfect dictionary. While quite willing to give all my readers every information they require, at the same time they should certainly remember a good old

saying that Providence helps those who help them selves.—J. J.

5400.—Orchids in plant-house (*K. T. Clark*).—I quibble with you (that *Odontoglossum Rossi majus*) by no means a warm-house plant or a difficult one to manage; but all are not of such an accommodating disposition, and you must get someone to answer your numerous queries who has had practice with a gas-stove, and knows more about its effect on Orchids than myself.—M. B.

5401.—*Coclogyne cristata* (*C. J. P. F.*).—Your plant appears to have made a good lot of new limbs. They are all, however, of a small size, and you cannot expect any flower-spikes from them. The fact of keeping to the *Odontoglossum* should not lead you to expect flowers yet, and being so treated I do not think it could have flowered so early as Christmas in any season.—M. B.

5402.—*Cymbidium sinensis* (*A. W. S.*).—You, like the rest of amateurs, appear to be much troubled about repotting. This plant requires rather a large pot for its size as the roots are thick and fleshy. The soil should be two parts good turfy loam and one part peat, well mixed. The plant may be potted now as soon as it has done flowering. The temperature will do.—M. B.

5403.—*Cypripedium Leeanum superbum* (*A. Grant*).—A grand flower of this hybrid and prolific species the name of *superbum*. It is very bright and showy kind. It was first raised by Messrs. Vetch and Son, and which time many others have obtained seedlings of a greater or lesser degree of excellence, yours being a very fine one, but still it must retain its original name.—M. B.

5404.—*Maxillaria tenuifolia*.—*H. H.* sends flowers of this species, asking if it is a new plant, saying he had never seen it before? This Orchid was sent home here nearly sixty years ago, and has been largely cultivated; therefore, I think "H. H." must be a young beginner in Orchid-growing, or he certainly would have seen it before now. I should advise "H. H." to grow the plants, which have long, dark, lanceolate leaves, and bright richly-coloured flowers produced in abundance.—M. B.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we do not answer queries taken from letters to correspondents, or insert queries that do not contain the name and address of sender.

C. J. B. Market Harbor.—Apply to Messrs. Richard Smith and Co., Worcester.—Mrs. Fullagar.—Apply to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, London, N.—E. M. P.—The better plan would be to grab up the fruit-trees and plant young ones.—A. B. G.—The Hoses are affected with green-fly and brown-scale. Fumigate with Tobacco and then wash with soapy water, applied forcibly with a syringe.—*Ignoramus*.—Your best plan would be to get a good local gardener to come in and look at your tree and advise you as to pruning. We cannot do so without seeing it.

NAMES OF PLANTS AND FRUITS.

* * * Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, W.C.

Names of plants.—*D. Bull*.—1, *Cypripedium Spicerianum*; 2, *Cypripedium barbatum*; 3, *Cypripedium venustum*; 4, *Anchidium flexuosum*.—*J. Buniler*.—*Diclyogramma japonica*.—*Hannah Burton*.—1, 2, 3, are very strange forms of *Sceloporus* vulgaris, which we shall be very glad to see again from this year's brood; 4, *Lastrea polypodiifolia* apparently, send again when fertile; 5, Looks like *Lastrea amabilis*, send when fertile; 6, Cannot determine.—*G. B.*—Cannot name from leaves only.—*Miss Morrison*.—1, *Asplenium germanicum*; 2, *Adiantum Capillus-veneris*; 3, *Pteris acrostichata*; 4, *Adiantum species*; 13, *Polytrichum angustifolium proliferum*. Would have named the remainder had they not been such very little pieces.—*Ernest*.—*Callitriche prelobata*; 2, *Adiantum macrophyllum*; 3, *Cheilanthes scabellata*; 4, *Polytrichum triangulatum*; 5, *Conocarpus javanica*; 6, *Onocleum harpoceras*.—*Henry Thomas*.—1, *Odontoglossum triumphans*; 2, *Odontoglossum crispum*, fair var.; 3, *Oncidium triquetrum*; 4, *Cypripedium Meirax*; 5, *Laelia autumnalis Arnoldiana*; 6, *Laelia alida bella*.—*G. Piggitt*.—1, *Trichomanes humile*; 2, *Hymenophyllum leptopteris superba*; 3, *Ceterach officinarum*; 4, *Adiantum formosum*; 5, *Nephrodium venustum*.—*R. How*.—1, *Eranthemum pulchellum*; 2, *Urtica racemosa*; 3, *Baccharis speciosa*; 4, *Humbugo cespitosus*; 5, *Maranta zosterifera*; 6, *Ophiopogon Jaburan variegatum*.—*Rosemary*.—1, *Cralagea Pyracantha*; 2 and 9, are apparently varieties of the common *Green Oak*; 3, *Sond in flower*; 4, *Biota orientalis*; 11, *Stachys lanata* (*Grey Wound-wort*). Other specimens of Conifers sent again when bearing cones. Please give your name and address next time and send good specimens.

BEEES.

SEASONABLE NOTES.

The wintering of Bees in straw hives is attended with much less trouble and risk than when wooden hives are used. When the combs do not touch the sides, as in the case of the bar-frame hive, the heat escapes round the ends of the combs, and extra precaution is required to be taken by the Bee-keeper in order to maintain the right temperature within the hives. If, however, the Bees in frame hives are crowded into as small a space as possible by means of division-boards, one on either side of the frames, and the space between the division-boards and the sides of the hive filled with chaff or Cork (or, better still, small cushions are used

outside the division-boards and over the frames, being stuffed with Cork-dust and sewn through and through to keep them in shape, all draughts are excluded, and with plenty of stores the Bees winter very comfortably.

WINTER TREATMENT.—During the winter the hives should be kept at a regular temperature as possible. Bees, as a rule, do better in cold winters than in mild ones. In cold weather they cluster into the centre of the hive, and in the severest weather become dormant; there thus being but little wear and tear, they live well into the spring. When snow falls it should be swept away from the neighbourhood of the hives as much as possible, or the frosts of the hives shuded from the rays of the sun, because when the sun shines upon snow numbers of Bees leave the hive, and, settling upon the snow, become chilled and unable to return; thus great loss is sustained. It is, therefore, a wise precaution to place something in front of the hives, on the appearance of snow, to form a shade from the rays of the sun. A good shield to use with the bar-frame hive is in the form of a hinged porch, which, when unsupported from below, leans on the alighting board at a distance of about 2 inches from the hive front, leaving easy means of exit at both ends. In front, opposite the entrance, there are two 4-inch openings, cut out of the lower edge of the porch, which gives easy access to the Bees alighting at their usual place. Other hives can be shaded by fixing before them, about 1 foot away, a wooden screen, nailed to a post sunk into the ground, and large enough to shade the whole front from the rays of the sun. Many of the old Bees of a colony die during the winter months, and are, as a rule, cast out of the hive. In very cold weather, however, the Bees are unable to cast out their dead, and in consequence it sometimes happens that the entrance of the hive becomes blocked; it is, therefore, good policy to pass a searching wire round the floor-board occasionally, with a view to removing any dead collecting there. If, on inserting the searching wire into the entrance healthy Bees are disturbed, and they show great activity, it may be taken for granted that the hive is in a prosperous condition, and attention need only be given to keeping entrance clear to promote ventilation; but if on withdrawing the wire dying Bees are discovered, it may be concluded that the colony is suffering from hunger or disease. The best thing to do in this case is to stop the hive entrance with a piece of perforated zinc, and carry it into a warm room, and supply the Bees with some warm syrup, so that they may get immediate relief. Upon their showing signs of returning life and activity the hive may be returned to its stand, and as the Bees become quiet from the excitement of feeding, the entrance may be unstopped, a cake of candy placed over the feed-hole at the top of the hive, and the whole covered up warmly. In the case of a bar-frame hive a feed-hole may be cut through the quilts over the frames.

KEEPING HIVES DRY.—Roofs of bar-frame hives should be examined, and where there is any doubt as to their being quite weather-proof they should be painted, barred, or covered with roofing felt. Where hives are in exposed situations precautions should be taken to guard them from the full force of strong winds. Roofing-felt makes very excellent covers for straw skeps, being very durable and impervious to water. Beneath these outer coverings plenty of warm material should be used. Outer cases of wood are also very serviceable for straw hives, and have the appearance of square bar-frame hives. Bees suffer from dysentery, which is brought on through dampness of hive, cold, and partaking of unsuitable watery food, such as unripe or fermented honey. All unnecessary manipulation and disturbance of Bees during the winter causes excitement within the hive and an undue consumption of food, and tends also to bring about this disease. Hives found to be foul with dysenteric discharges may have the combs and Bees transferred to fresh clean hives during mild weather, all soiled frames being scraped and washed over with a weak solution of carbolic. The Bees should be supplied with a cake of candy, or a comb or two of sealed stores, the division-boards moved so as to reduce the size of the hive to the number of combs covered by the Bees, the spaces filled up with chaff or

Cork-dust, proper ventilation given, the hive well protected from cold, and the Bees disturbed as little as possible.

S. S. G., *Sturminster Newton.*

POULTRY AND RABBITS.

5272.—Poultry keeping.—It certainly is not injurious to keep a hen in darkness whilst she is sitting, but is rather to be desired than otherwise, for in my opinion hens sit more steadily and the broods are more successful when they are out of sight in as secluded a spot as can be found. Of course "Kitty Belluwa" will take care that there is some fresh air obtainable and will not sit the hens in a small box and refuse the light, so to speak, upon her. With regard to feeding the laying hens at this time of year, I prefer to use sharps and Spratt's meal mixed with hot water for the first feed in the day. I occasionally add a little cress or mixed meat, and should the mornings be very keen I should give some earlote which answers much the same purpose as crumbe. Shortly after dinner the fowls are fed with hard corn, Buckwheat or Wheat for choice, but now and then I may give a feed of Barley. I never use Indian Corn. If a hen will not roost with the others, but gives a lot of trouble, I should certainly send her to the kitchen, unless she is extremely valuable for breeding purposes. It must be remembered that the cost price of an ordinary hen is not as a rule very high, and therefore it cannot pay her owner to spend much time upon her. To sell or kill the offender would thus appear to be true economy. —DORRINA.

—Fresh eggs at Christmas.—If there is one thing which causes a poultry keeper to feel annoyed with his birds and everything around him during the winter months, it is the fact that while his fowls are doing nothing what-aver towards earning their keep, his neighbour's poultry are laying freely, in spite of frost and snow, or rain, as the case might be. The case is doubly trying when good housing, the best of feeding, and careful selection of stock are all attended to, for the owner has then good reason to feel disgusted with his stock. One important point remains, and it is to the neglect of this simple matter that so many owe their failure to procure eggs at midwinter; it is to hatch at the proper time. It is out of the question for pullets to lay at the beginning of October, unless they are fully six months old, yet this is what many expect them to do. What, then, I would urge at this moment upon the readers of GARDENING, is that they should take time by the forelock, and contrive by some means or other to have some chickens out by the middle of March. Then they may look forward to an abundance of fresh eggs from October onwards, and for once in their lives be in a position not only to supply their own wants at a season when fresh eggs are scarce and a luxury, but also be able to meet the demands of their neighbours. —DUFFING.

BIRDS.

5105.—Crossing Canaries.—I am anxious this spring to try crossing between a Nonpariel bird and hen Canary. Would anyone who has tried the experiment tell me if they were successful, and if the young ones were delicate to rear? Any advice on the subject would be gratefully received. —J. F.

RUGS! RUGS! good, all-wool; 8 ft. long, 6 ft. wide, and weigh over 4 lb.; Government grey; only been used a little; much better than common now.—I will send one post free for 3s. from H. J. GASSON, Government Contractor, Eps.

FLOWER POTS. 12 8-in., 20 6-in., 50 3-in., 50 4-in., 50 3-in., packed in cases and sent to rail for 7s. 6d. Cash.—H. GILLIBART, Bultery, Belmont road, Heckham.

PROTECT YOUR GARDENS.—Garden netting, oil and dressed; will not rot if left out in all weathers. 100 yards by 1 yard, 3s.; 100 yards by 2 yards, 4s.; 100 yards by 3 yards, 5s. No use in any width. Carriage paid on all orders over 5s. I do not require payment till you have received and approved of the writing from—H. J. GASSON, Hardware and Wares, Eps.

DON'T FORGET!—The Patent Invinicible Crook for plant-pots keeps out worms and all vermin; saves time, expense, and annoyance; its own pot; lasts for many years; will be used in every garden when known. 20 lb., 10s.; 10 lb., 5s.; 5 lb., 2s. 6d.—A. FORSTER, Stone House, Maidstone.

RAFFIA for Garden Tying.—Hear Quin's! Cash with order; carriage free. 1 lb. 3d.; 2 lb. 6d.; 5 lb. 12d.; 7 lb. 18d.; 10 lb. 24d.—CLIFFORD, 35, Bank-st., Maidstone.

G. HAYWARD F.R.H.S.

CRYSTAL PALACE HORTICULTURAL WORKS, 359, BROCKLEY ROAD, BROCKLEY, LONDON.

2, Park-st., Stoke, Devonport, Nov. 17th, 1893. Dear Sir,—In answer to yours of the 15th soliciting an order, I beg to inform you I wrote for the Price List of Greenhouses for Mrs. B. Belmont-place, Stoke, and persuaded her to purchase the smallest greenhouse which you sent her. This is not the first greenhouse I have had sent from London, but I must say this is the prettiest and best house I ever saw for the money. Any customer of mine requiring a greenhouse or frame I shall do my best to send you the order. The little Tower Heater answers splendidly.—I am yours truly, J. STEVENS.

ILLUSTRATED PRICE LISTS FREE.

This is Hayward's No. 1 and No. 2.

No. 1 Span-roof and No. 2 Lean-to Greenhouses are prepared especially for amateurs, made of Best Red Deal, thoroughly seasoned, completely fitted with Ventilators, Door, Stays for plants, Painted zinc coat, 16-oz. Glass, all necessary iron-work. Delivered and packed free on rails at the following prices, satisfaction guaranteed. Write for New List.

Table with 2 columns: No. 1 Span-roof and No. 2 Lean-to. Rows show dimensions (7 ft. long, 5 ft. wide) and prices (£2 10 0, £2 8 0, etc.).

For other sizes and prices write for Illustrated List to

G. HAYWARD, 359, BROCKLEY ROAD, BROCKLEY, S.E.

NATIVE GUANO. BEST AND CHEAPEST MANURE FOR CAROEN USE.

Price £3 10s. per ton, in bags. Lots under 10 cwt., 4s. per cwt.; 1 cwt. Sample Bag sent Carriage paid to any Station in England, on receipt of P.O. for 5s.

Extracts from 18th Annual Collection of Reports: NATIVE GUANO from PATAPUES, VICTORIA, B.C. It is the best manure for Potatoes, Turnips, and Carrots; results: "Very good; never had better crops." A. J. ALLEN, Gardener to Lord Portman:—"A better quality Guano I don't wish to have. I can thoroughly recommend it as a valuable manure for vegetables."

NATIVE GUANO for PEPPERS, RUSES, TOMATOES, &c. R. McINTOSH, Harbinger to F. T. Cuddihy, Esq., Edin. shows: "For Cucumbers, Melons, Peaches, and Vines, it is my favourite manure. For Vines in frames, Chrysanthemums, and nearly all kinds of plants, we use it with excellent results." H. HICKMAN, Gordon Road Nursery, S. Woodford:—"Used for some years, and am satisfied it is the best manure of the price I ever had. Specially good for Cucumbers and Tomatoes." Orders to the NAVEO Guano Co., Ltd., 20, New Bridge Street, Blackfriars, London, where Pamphlets of Testimonials, &c., may be obtained. AGENTS WANTED.

EVERYONE WHO HAS A GARDEN, GREENHOUSE, OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. WITH, F.R.S., F.C.S., Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. Shows how crops of vegetables may be largely increased, lowers flowers grown to perfection, and fruit-trees enable to bear in abundance. Selections from Hundreds of Testimonials. Post free from JAKEMAN & CARVER, Printers, Hereford.

GARDEN NECESSARIES.—Virgin Cork, finest, 112 lb., 17s.; 56 lb., 10s.; 28 lb., 5s. 6d.; 14 lb., 3s. Bamboo canes, 4 feet, 3s. per 100. Tobacco-paper, strong, 1s. per lb. Yucca cuttings, 6d. lb., and 1s. 6d. each. Raffia 1s. per lb. Cocoon-fibre, 1s. 3d. each. Mannins, Mats, Garden Sticks and Labels, Sand, Post, &c. Price List on application.—WATSON & SULLIVAN, 29, Lower Thames-street, London, E.C.

LOOK! LOOK!! LOOK!!!—Greatest Bargain on Earth, 10,000 WATERPROOF THINGS and CAPS.—I purchased from Government. Cost 7s. 6d. each. I will send a Hood and Cape for 21 stamps, post free. Quite new, but put out of service.—H.V. JOHN GASSON, Government Contractor, Eps.

GREENHOUSE MATERIAL.—Red Deal Sash-latt, 3 in., 6s. 3d.; 2 1/2 in., 5s.; 2 in., 3s. 9d. Slide plates, 4 in. by 3 in., 10s. 6d. per 100 lb. run. Prepared timbers (not fitted), including floor and roof ventilators for forcing-houses, 20 ft. by 12 ft., 25; 40 ft. by 12 ft., 35. Insurance done for building free to customers.—J. FAIRBANKS, 217, 11, first-road, Reading.

BAILIFF AND WOODREVEE.—A gentleman recommends an active, trustworthy man as BAILIFF or WOODREVEE, or both, on a small wooded estate. English name, used to fruit and woodland work.—Address B. F. E., care of Editor of FARM AND HOME, 37, Southampton-street, W. U.

WANTED.—A Man who knows the lending Gardens and Horticulturists in the United Kingdom to sell a Specialty of an edging and covering.—Address H. H. GARDNER, 217, Deodar-street, London, E.C.

GENTLEMAN recommends good Gardener with good experience in early flowers, Roses, Chrysanthemums, and 32 varieties in family; good character.—O. BIFFE, care of Editor, 37, Southampton-street, Strand.

OUTLAGE WITH GOOD GARDEN.—A Cottage with large garden or field, in the beautiful Home Counties.—Address full particulars to "GARDENING," 11, Abchurch-lane, London, E.C.

FAWKES' SLOW-COMBUSTION HEATING APPARATUS

Most Efficient and Cheapest in Existence.

Requires no sink or boiler and no brick setting. Will last all night without attention. Will burn house chimneys, therefore makes next to nothing for fuel. Anyone can fix it. A domestic servant can stoke it. SUCCESS GUARANTEED.

Enormous numbers in use all over the country. ONLY SLOW-COMBUSTION APPARATUS OF THE KIND. Complete Apparatus from £4 12s.

CAUTION.—Beware of imitations. Incomplete apparatuses which will not heat all night.

Full particulars and prices of every sized apparatus and numerous testimonials for five seasons, showing numerous success, post free on application.

BEST CONSTRUCTED and CHEAPEST Greenhouses, Forcing Houses, Pits, Frames, Plant Protectors, Poling Sheds, Tool Houses, &c.

Illustrated Priced Catalogue post free from CROMPTON & FAWKES, CHELMSFORD.

FIRST-CLASS SILVER BANKSIAN METAL

Awarded by the Royal Horticultural Society, 1893.

THE DUCHESS

We are the first inventors and makers of this style of Heating Apparatus; all others are outward imitations only. Price: No. 1, to burn oil with 6 feet flow and 6 feet return of 3-inch pipe, 34s. No. 2, to burn oil with 6 feet flow and 6 feet return of 3-inch pipe, £2 2s.; fitted with Hink's best Duplex Burners for oil, or Fletcher's best burners for gas. Complete and guaranteed. We also make a cheap imitation of the Duchess, of cheaper material and workmanship, consisting of 5 feet flow and 5 feet return of 3-inch pipe, for 17s.; or 6 feet flow and 6 feet return of 3-inch pipe for 18s. 6d., including ordinary lamp or gas burner. Illustrated Catalogue of New Titles sent post free.

FERNS.

EASILY-GROWN FERNS.

As the season is approaching when Ferns are purchased, it may be useful to point out a few of the vigorous, easily-grown Ferns that will thrive in a greenhouse not much heated. Those mentioned will also succeed in a room, resisting better than any others the trials of such a place.

The *PRELATES* afford much variety, and all the kinds enumerated are of vigorous growth. *P. cretica* is one of the best, and should come into the smallest list of Ferns for the greenhouse or room. There are several varieties. One is named *albo-lineata*, the central line of white running down the frond adding much to its attractiveness. Another good variegated variety is *P. e. Maji*, which is very finely marked with silvery-grey, and is not less strong in habit than the type. Crested Ferns, as a rule, are not beautiful, nor has the variety named *nobilis*, a crested form of *P. cretica*, the elegance of the parent; but it is a good sturdy variety, the habit is bold, and the crested fronds stand up well. But, firstly, get the type *P. cretica*, and then the variety *albo-lineata*, as these are cheaper than the others, whilst the latter may be added as the interest in Ferns deepens. *P. tremula* is a thoroughly useful Fern. I have kept a specimen in full beauty for several years in a room, standing it out in warm weather to get the advantage of gentle rains. The plant is elegant in habit, and the fronds of a light-green colour. Two forms may be noted as of importance—one is called *Smithiana*, a very finely-crested Fern, vigorous in habit, each frond being split up into what we may call *fronlets*, which individually terminate in a dense tuft, not ugly by any means, as in some of the curious, not to say fearful, monstrosities of the *Scelopendrium* or *Hart's-tongues*. There is also a variegated variety of *P. tremula* named *variegata*, similar to the type in habit, but each of the pinnae is marked with a linear line of silvery-white. *P. serrulata* is not so well adapted for rooms as the others, but it will succeed well in a warm greenhouse, and the crested variety of this is well worth noting. It makes a spick, vigorous growth, and is in every way a thoroughly useful Fern. *P. t. Smithiana* is a heavily crested form.

The *NEPHRODIA* for baskets are difficult to heat, and *N. exaltata* is the cheapest and best known. It makes a splendid basket Fern, the long fronds hanging down over the same in a graceful way, but it requires the temperature of a warm greenhouse and plenty of water in summer months. Basket plants require soaking, or the water, if the drainage is in good order, quickly runs away.

AMANTHUS is the most useful of the Maiden-hairs, especially for cutting, the fronds lasting extremely well. It is needless to describe this Fern, which is unquestionably the most popular in cultivation. A very beautiful Fern is the variety of the hardy *A. capillus-veneris* named *Mariesi*, the fronds of a rich green colour. Of course, there is a host of

lively *Adiantums*, but they require heat, and the object of these notes is to mention merely those to form the nucleus of a collection or one as easily grown as any kinds. The same remark applies to the

ASPLENIUMS, of which *A. bulbiferum* is the most readily managed. Other useful Ferns are *CYRTOMIUM PALMIFOLIUM*, an excellent kind for rooms, the fronds quite feathery in texture and deep-green, the *Hart's-foot Fern*, *Davallia canariensis*, *Lastrea cristata*, and its variegated variety, which has deep-green fronds, each marked with a yellowish linear stripe, so to speak.

ONYCHIUM JAPONICUM is a useful Fern, and difficult to kill. I do not mean by this it is happy under any treatment, but it is a thoroughly vigorous kind. Many of the

HARRY FERNS are well worth growing in pots, especially varieties of the Lady Fern, as *Athyrium Filix-foemina superbum* and *plumosum dissectum*, which are new kinds, as yet rather expensive—at least, plants cost about half-a-crown each. The fronds of the flower are finely crested, and those of the latter delicately cut. A very beautiful variety of the male Fern is *Lastrea pseudo-mas cristata fimbriata*, the fronds of quite a delicate texture, and tasselled in a charming way. There are several good forms of the *Hart's-tongue* also, one named *capitatum* having handsome, tasselled fronds. It is a common mistake in the winter months to keep Ferns in the greenhouse and rooms too dry; the soil should never go dust-dry, but less water is required than in the summer months. More failures result from this mistaken management than from any other cause. *ARATROPIL*

Killarney Fern.—I have had a root of this Fern for some years. I have kept it in a dark corner of the hall, and have watered it very little at the root; but it has had almost daily syringings from a throat-spray over the leaves. It is planted in peat, and has a bell glass always over it.—M. C. B. H.

NOTE.—Ferns for a case.—The best Ferns for a case in a town are such hardy kinds as *Filix cretica cristata*, *P. e. albo-lineata*, *P. serrulata*, with an *Adiantum* or two, such as *A. elegans*. Along the front of the case *Pteris tremula* does very well, but soon gets too large. *Brachium latifolium* thrives well, and has dark-green Mahonia-like fronds. It is sometimes called the Holly Fern.—E. H.

5357.—Ferns for a bank.—You might grow many charming Ferns in the mountainous positions, such as forms of the Lady and Male Ferns, *Scelopendrium* (*Hart's-tongues*), the *Blechnum*, and all the commoner kinds, if they are not exposed to drip. Ferns do not like drip, and the fronds soon wear an unhealthy aspect if exposed to it. In shady places Ferns are the best things that can be planted. I had once a corner against a wall where nothing would grow through absence of sun, and generally unpleasant surroundings. Ferns were tried, and the soil made good by incorporating with it plenty of peat. Good clumps were planted, and in time with careful attention, copious waterings through a hot summer and gentle syringing of the fronds occasionally, they made a remarkably well spreading out into bold luxuriant masses. This was attained, too, in a suburban garden where little could be got to

thrive. As it is a bank, it is all the more necessary to take care that during the first summer, at least, water is freely given.—C. T.

—Any of the hardy British Ferns would do admirably here, if planted in suitable soil. Ferns do not require much sun, and, in fact, succeed best, as a rule, in moderately shady places. A few suitable ones would be the common Male and Lady Ferns, the Basket Ferns (*Lastrea*), the Shield Ferns (*Polystichum*), the *Polypodies*, the *Hart's-tongue* (*Scelopendrium*), &c.—B. C. R.

5322.—Asphalting.—"Bart" put too much tar to the shingle; he ought also to have mixed about one-eighth weight of mineral pitch with the tar—say, 14 lb. pitch to 112 lb. tar. Boil them together until all the pitch is dissolved, stirring it well to prevent its boiling over, as it is likely to do unless kept well stirred. Mix the shingle after drying it well, as moisture will not unite with tar, and lay it down as hot as possible, and roll it well, throwing a little wet sand on the roller, as it turns round. By following this plan he will get a good walk for several years. Take the loose material up and reboil it, adding the pitch as above.—R. N. M.

5375.—Raising plants from seeds.—The plants raised will all come to perfection this summer raised from seeds. It will be better to sow *Phlox Drummondii*, *Verbenas*, *Sedum*, and *Antirrhinum* under glass in a little heat to flower early. Any time during February or March will be time enough to sow. Sow *Cyanus*, *Poppies*, *Smileflowers*, *Clarkias*, *Echscholtzias*, and *Careopsis* outside in March. The other plants named, if there is no glass, may also be sown outside in a warm, sunny border end of March or beginning of April, according to the season.—E. H.

—By *Cyanus* I presume you mean the *Cornflower*. This and all the others, except the *Antirrhinum*, may be sown in the spring for a summer display. The *Phlox* must be sown under glass, and it is a splendid flower for the garden, well worth making even a distinct bed of. A good catalogue will show you what a variety of kinds there are, the flowers presenting considerable diversity of colour. All the others may be sown out-of-doors. Sow thinly, and give each plant sufficient space to develop its own natural beauty, impossible when crowded up into a mass. The *Antirrhinum* is a biennial, and may be sown in the summer or as soon as the seed is ripe in the open. It is very readily grown, as may be surmised. Avoid the pigmy plants, dwarfed by some recognition almost, which some are pleased to admire and praise. They are the most horrible things I have seen amongst so-called novelties.—C. T.

5356.—China Asters, &c., from seed.—Very thinly; both Asters and Marigolds may be raised in a cold frame with perfect success, if placed in a warm and sheltered position. Sow the seed from the middle to the end of April, according to the locality and the weather, throwing a mat or two over the glass on cold nights.—B. C. R.

Asters and Marigolds may be raised in a cold frame. Sow the seed in a cold frame or hot bed in April, and more tender than Asters. The least frost injures them when young.—E. H.

GARDEN WORK.*

Conservatory.

Tea and Nolsette Roses will now be showing flower, and must be kept free from insects. Tobacco-powder is useful where it is not convenient to fumigate. Spraying and clipping may also be resorted to with success. Soapy-water, with a dash of Tobacco-liquor mixed therewith, makes an effectual wash, and on bright days a good deal may be done with the syringe and clean water. All the syringing should be done in the forenoon, so that the leaves may be dry before night. The Chrysanthemum cuttings, for the production of large blooms, will now be pretty well all in, and the early cuttings are all rooted and placed on a stage in a light cool house to keep them strong and sturdy. For general decorative work cuttings may still be taken, and if the plants are grown on without check they will do good work. Fuchsias starting into growth should be put into shape and repotted, shaking away a good deal of the exhausted soil, and shortening back a few of the largest roots. A cherry at work will be a good place for the production of large blooms. Pelargoniums will now have had their final shift, and must have a light position near the glass. The early blooming varieties will soon be showing buds, but late roses may have the strong shoots stopped once more. Zonal Pelargoniums which have exhausted themselves by flowering through the winter may be cut back, and the cuttings put in. The plants struck now will be useful for flowering next winter. Primulas, Genetias, and Cyclamens are now very bright and effective. Galatarias should have a final shift into 7-inch pots. If large plants are required, keep these plants in a cool place not much exposed to sunshine. They will do well in a north house. If exposed to sunshine the leaves will probably lose colour. All well-rooted plants coming into flower may have liquid manure occasionally. Mignonette just showing flower will be improved by an occasional dose of some stimulant. Heads which have done blooming may have the young shoots shortened back, and be taken to a house where a little warmth is kept up, to encourage growth; but the night temperature for them need not exceed 45 degs. Buds of all kinds coming into bloom may have liquid manure, as may also both Indian and Japanese Azaleas, but it should be weak and clear. Tree-Carnations should have a temperature of 50 degs. to 55 degs. to bring out the colours well. As soon as the Linnæas have done flowering shoots should be trained back to about three buds. This plant is not considered an easy one to propagate, but the young shoots, when about 3 inches long, taken off with a small leaf, will root under a bell-glass in sandy peat. The bell-glasses must be wiped dry every morning to prevent damping; and this refers to the propagation of all plants under bell-glasses. Begonias, Justicia, Poliosettas, and other plants taken from the store will now be past their best. Some may be thrown out, and a few of the best only reserved for cuttings, which should be rooted now as soon as possible. There will be a constant stream of forced flowers coming in now from the forcing-house, and to meet the wants of these the ventilation must be carefully managed, avoiding cold draughts.

Stove.

Cuttings of many things may be taken now. Where there is no regular propagating house a case for striking cuttings and raising seeds may easily be improvised over the hot-water pipes, a plugging bed of Cocoa-nut-fibre being made inside. Camælas are beautiful things, though I think hardly so popular as they were. They are easily grown in a warm house with a moist atmosphere. The greatest difficulty in their culture is to keep them free from mealy-bug. Wherever this insect is present an effort should be made to chase them out before the flower-buds are prominent. Cuttings of the young shoots will strike any time in a close frame with a brick bottom-heat, and small well-furnished plants in 5-inch pots will produce several flowers. Alantums and Begonias should receive what pruning is necessary, and in the course of a fortnight should be repotted. Lianas and other hard-wooded stove plants may soon have a shift if required. The night temperature now may range from 40 degs. to 60 degs. As the days lengthen more warmth will be required at the roots of the plants, and also in the atmosphere of the house. Early flowering lilies, such as Gloriosa and Adonis, may be started. Some of the former will now be showing flower-buds if started early enough. Any thing that requires repotting may now have its roots started into growth. They will do best plunged in a bed of Cocoa-nut-fibre on a bed or stage not far from the glass.

Ferns under Glass.

This is the best season for repotting Ferns, beginning with the hardest varieties first; but it is not advisable to let the young growth advance much before repotting, especially if the plants are intended to be shifted to make a stock. Young growing Ferns may be repotted any time when a plant is merely shifted from a small pot to a larger one; but whenever division is necessary it is best done just as the new growth is making a start in spring. Loam is used more for Fern growing than was the case in the past, and the plants do better in good loam lightened with leaf-mould and sand, than altogether in a peat and compost. Spores may be sown now to raise young plants. Small plants in thumbs and small 60's are a good deal sought after now for filling small vases to stand on the drawing-room table, and small well-grown Maiden-hairs are useful on the dinner-table. Ferns are charming basket-plants, and no fernery is properly furnished without a few well-filled baskets. Some families are well adapted for baskets. All the Nephrolepis and Darwins do well in baskets, or other of the same kind, but I prefer the home-made wire, the wires being well covered with Moss and creeping plants.

October House.

Strong plants set out now in a warm house where there is a comfortable bottom-heat will soon make rapid progress. Bottom-heat of some kind there must be, though

it need not be hot-water. Very good crops of Cucumbers are grown in houses where the narrow pits in which the Cucumbers are planted are filled with stable manure, the Moss-litter-manure being the best. It must, of course, be fed from the stable so that a brisk heat will be maintained as long as the Cucumbers require it. I have one house, the only bottom-heat of which is German Moss-litter-manure, and the plants do so well that I should incur the expense of pipes in any house planted in February or later. The top-heat would, of course, be regular and steady from hot-water. In raising Cucumbers or Melon-plants at this season it is well to have a dozen or two of plants to spare rather than plant weaklings.

Cold Frames.

Many of the cold frames will now be placed on beds of manure to force various things in. For wintering plants which require protection a turf pit is better than a wooden frame, or even a brick pit, so far as regards keeping out frost. Anyone can build the walls of a bed with clay soil or turf cut from an old pasture. In the course of a few years the banks may be taken down, and the product used as potting material, and a new pit built with fresh soil.

Window Gardening.

Genetias in flower are now common, and if the flowers are to hold on well the plants must be watered, and a little stimulant will be useful. In towns the gas has been the greatest difficulty to plant growing, but this will soon be altered now as the electric light is coming into general use, and it will then be the fault of the grower if the plants die suddenly. The best plants to stand the gas are Aspidistras, Bravancas (green-leaved sort), Fainas, India-rubbers, Casts, Aloes, and Mosenyriastricums.

Outdoor Garden.

The early flowers will soon be showing colour; some are, in fact, now in bloom—Snowdrops, Aconites, Primroses, and the early white-flowered Arabis alba—and Iris reticulata in throwing up its spikes on the sheltered rockery. Wallflowers are in bud and will soon scatter their sweetness in many sheltered gardens. Wallflowers grow and flower best in hard dry ground. If grown in a frame, and is less liable to injury from severe frosts. Some of the double Wallflowers are very fine, but they will shelter in cold weather. I am growing them in pots in a cold frame. A few will be potted immediately into 5-inch and 6-inch pots for the conservatory, and the remainder will be planted out. Turf goes down well now and the roots will soon get to work. Box-edgings may be planted, and various trees and shrubs of all kinds will transplant safely. Some of the things which everybody ought to plant are: Acacias in variety, Almonds, Honeysuckle, Cherries, Prunus Pissardi, The Prunus and the Silver Maple in mixture makes a very pretty division line or hedge in a garden. Birch a hedge had a very striking effect in Messrs. Paul and Son's nursery at Brookbourne last summer. Their nursery also contains much in the way of hardy plants that is worth a visit, and the plants both on the rockery and the border may be seen in masses, and this gives a very different effect to the different plants. I was asked the other day, "Why do you not try to grow Hepaticas? I have mired them at all seasons with a fair amount of success, but I suppose there is a best time, which I should take to be October; in fact, I think all early-flowering subjects should be sown in October. They then get established before cold weather sets in, and are in a condition to support the blossoms when they expand. What a charming thing Primula rosea is! A shady nook in the rockery is the place for it, and all Primulas in fact.

Fruit Garden.

Those who intend to do any grafting should secure the grafts at once and lay them in a cool position in the north side of a wall till they are wanted. Finish training Plums and Apples on rails. Peach-trees also may be pruned and trained, though in some instances the training is delayed until the time of returning the blossoms. If there has been any trouble with insects in the past season give the trees a good washing with Gishurst Compound, 4 oz. to 6 oz. to the gallon. The best and most economical way of using the wash is to use a brush for the large branches and a sponge for the young wood. This dressing will carry the trees well through the blooming period, and a little Tobacco-powder will keep them clean till after the covers are removed, and then the garden-engine and the soap-suds from the laundry may be used, or a slight remedy dissolved in warm water can be used. The present genial weather is good for the Strawberry-forever, as it permits of all being given. The camel-hair, or some other means, must be adopted to induce the blossoms to set well, and the thing should be done as soon as the best shaped and largest fruit can be selected. Preparations must soon be made for overhauling the Pines, where they are grown extensively. Many have discontinued growing Pines, which I think is a pity. It is perfectly true that it is expensive, but the Pine-stick is generally used for other forcing purposes. Flowers for cutting, French Beans, and other things may be grown on shelves to help pay for fuel. The early vinery, with the Grapes just ready for thinning, or, perhaps, just being thinned, should have a night temperature of 60 degs. to 65 degs., the lowest point being usually reached about sunrise in the morning. Do not crowd the young wood. There is a great temptation to lay in too much wood, and the foliage, in consequence, is small, and this in turn reacts upon the fruit. Errors have very often a far-reaching effect.

Vegetable Garden.

Autumn-sown Peas, which are now up, should be staked, a ridge of soil being drawn up on each side before starting. We are not yet out of the wood as regards frosty weather, and it might be advisable, where there is the means to do it, to sow a quart or two of a good early kind in pots to be planted out in March, or when the weather is settled. There are plenty of early Peas to select from now, and good selections of the old sorts, such as King Edward, William I., Dickson's First and Best, Keuthen Violet, and others will not disappoint. Keep up a successful supply of forced Seakale, Asparagus, Rhubarb, and Mushrooms. These are all necessary in a first-class establishment, and many good-class places have them in considerable abundance. If it is not a question of providing the means, make Peas, for instance; it is much easier produced than

Asparagus in winter, and the beds need not be large to produce a moderate supply throughout the winter months, either in the old-fashioned way, or covered with mats surrounded with fermenting material, or the roots lifted and planted 3 inches or 4 inches apart in the Mushroom-house, or planted in deep boxes and placed in a warm corner under the stage in the greenhouse. I have seen Asparagus forced in boxes and baskets, the roots being packed closely together in the baskets and covered with light rich soil, the baskets being placed in the vinery or any house where there was sufficient heat to start the plants into growth. There is abundance of Winter Green of all kinds as the plants made up their lost time in the autumn, and the frost since Christmas, though rather sharp whilst it lasted, has done but little harm. Early Cabbages on warm borders will soon be turning in, and the forwardest may have a string of netting placed round the hearts, drawing up the leaves loosely. Do not forget that the early border may be cropped as soon as the soil workable. E. HUBBAY.

Work in the Town Garden.

No plant thrives better in the smoke and dust-taken atmosphere of a large town than the Vine, and though its near relation, the Virgularis Creeping, also succeeds equally well, on the whole the foliage of the Vine is the more handsome of the two; and then there is a chance of getting a few bunches of Grapes in a fine, warm season. For covering bare and ugly walls and fences outside there is no better subject than a Vine of some hardy variety, such as the old Sweetwater, the Royal Muscadine, Chasselas d'heret, or the Black Winter, and even if no fruit is produced the foliage is most useful to the eyes. As a climber for covering the roof of the town greenhouse a Vine is rapid or superior to anything else, and even within a very short distance of London Bridge I have succeeded in obtaining very thick bunches of Grapes from such varieties as the Black Hamburg, Foster's Seedling, and the Black Sweetwater. If the growth is kept thin the shade afforded by the leaves is grateful rather than otherwise to plants in pots beneath during the summer time—certainly to such things as Ferns, Palms, Fuchsias, Begonias, and others—and with ordinary care a very decent crop of Grapes may be obtained. Where the Vines have not yet been pruned this should be done at once, as if any artificial heat is employed the sap will be beginning to move again very shortly. The rule is to cut back all the young shoots of last year, whether they bore fruit or not, to a good joint eye near the base. Sometimes the second bud will be sufficiently strong, but the third is often a better one, and if you want fine bunches it is better not to prune too hard. When the spurs get long and saggy it is an easy matter to cut the rod right out and run up a young and vigorous one from the base. The best time to plant Vines, whether indoors or outside, is just as the buds are beginning to plump up, and on the point of starting in the spring. Get plenty of boxes, pots, soil, &c., ready to begin sowing seeds and striking cuttings of many subjects very shortly, and the seeds at hand. Sowing is a mistake, if any, or the beginning of March, often the better than the start earlier, especially if the amount of heat at command is limited, or the situation is very smoky, or lacks sun. Such things as Lobelias, "Golden Feather," Pyrethrum, Mimulus, Petunias, Verbenas, Centaureas, Chærisia maritima, &c., always better, however, when sown reasonably early than when left till later, and having to be pushed on rapidly to heat. Cuttings of Zonal Pelargoniums may be inserted at any time now in a rather dry heat. H. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from February 2nd to February 10th.

Put in cuttings of many things, including various bedding plants, soft-wooded stove plants, and other things suitable for the conservatory in winter. Salsolas are very useful when one has a large house to fill in winter, and cuttings rooted now and planted out early in June will make large bushes by September. It is very important to get the cuttings of all plants intended for winter blooming in early, including Zonal Pelargoniums; but these will do best in a dry heat, generally strike mine on a shelf over the hot-water pipes, and they will be the kept moist, and the soft young shoots, of which plenty have been produced by the plants which have been flowering all winter, will strike with the greatest certainty; but other soft things will be rooted in the hotbed, the bottom-heat being about 80 degs. Put in cuttings of Tree-Carnations. These also are rooted freely in sandy soil kept moist in a brick bottom-heat. Potted off Tomatoes, I want to get these strong to go out into a house now being prepared for them. Salsola is a mistake, I think, to turn out out-bound plants. As soon as the roots have passed through the soil, and can hold it together, the plants should go into the border, or the boxes if boxes are used. For an early crop I like boxes, but for summer and autumn gathering the plants are better with more root-room, and involve less labour in watering. Cucumbers set out just after Christmas are now running freely, but will be stopped. They have travelled some 4 feet or 5 feet up the rafters. Early stopping may give a few fruits earlier, but it detracts from their vigour. I believe if we could wait till the main stem was 6 feet up the rafter before stopping there would be a gain in the long run; but when Cucumbers are wanted the only means of getting them must be adopted. Sowed more early Peas, and planted more early Potatoes. The Beauty of Helbron type does well with me, and as it is a good cropper that rarely is planted largely. Meant's Prolific is another sort which always gives a return. Early Potatoes are always planted on well-manured land, and when the Potatoes come off the land is ready for another crop immediately. Sometimes Turnips are sown, or Strawberries planted at once, or Brussels Sprouts are planted between the rows of Potatoes whilst the latter are still growing. Potted more Chicory. The blanched leaves come in useful as a salad. A succession of Mustard and Cress is kept up by sowing in boxes twice a week in heat. Radishes sown in a frame on a gentle slope have just coming up, and will be ready for use in frames or hotbeds, and

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated, with a few exceptions.

soon as the Asparagus-roots are exhausted and removed early Potatoes are planted, which have been started in boxes in gentle heat, and after the Potatoes are lifted some other crop will be planted, such as Cucumbers, Capseiums, or Tomatoes, so that each bed carries three crops, and the manure afterwards comes in useful for the garden, after being turned and incorporated. Sowed a bed of the Queen Onion. Though not large it turns in early, and is always useful. Sowed a box each of Sweet Basil and Marjoram to have it early. Mint, Tarragon, and Chervil are required in a green state. The latter stands outside very well in the average winters, but it is always advisable to have some inside to provide for bad weather. Stirred the soil among spring flowers in the beds and borders. Bulbs are pushing through, and care is necessary not to disturb these.

OUTDOOR PLANTS.

MECONOPSIS.

The most familiar of this genus is our Welsh species, *M. cambrica*, a true perennial, while the others, natives of Northern India, two of which only are found in general cultivation, are only of biennial duration. They are all, I believe, quite hardy, but require considerable attention on account of their biennial duration, as they have to be raised annually from seed, the seedlings requiring great care in handling while in a young stage. They are also difficult to please as regards position, and strong, vigorous plants are almost impossible, unless in rich, deep, light soil and a partially shady situation, where they can have abundance of moisture without its becoming stagnant. The better way in handling seedlings is to grow them in pots during the first winter, planting out early in spring, when the stronger plants may be expected to show flower in July. The smaller ones will go on growing, forming large rosettes which will make robust specimens the following summer. Unless under the most favourable conditions a slight protection will be required in wet autumns and winters, this being best effected by squares of glass raised a few inches above the crowns. All the species usually flower the second year, and the grower's aim should be to get as much vigour into them in that time as possible.

M. ACULEATA is usually a small plant in gardens, but capable under proper and liberal treatment of forming bold, massive pyramids of purple flowers. It is a singularly beautiful plant. The leaves are cut up as in *M. Wallichii*, and the flowers are produced much in the same way. It is a biennial also, and a native of the Himalayas.

M. CAMBRICA.—For the truly wild portion of the garden, for the rock garden, or for the flower bed the Welsh Poppy is one of the most charming and useful. On old crumbling walls wherever it can get hold its ample Fern-like foliage and abundance of orange-yellow blossoms are striking and attractive. It will grow almost anywhere. It requires no attention, unless that of thinning out occasionally, as it is a free grower and will overrun almost anything. On the other hand, where it can be allowed space in out-of-the-way corners, stony ground, or even the edges of gravel paths, it flowers freely.

M. NEPALENSIS, the commonest Indian species, found in gardens, is altogether smaller than *M. Wallichii*, but withal a pretty fine-folaged plant, and on this account alone should be much oftener seen in collections of hardy plants. The soft yellow-green leaves form dense rosettes, which are said in a young state to close up or fold over as a protection to the tender crowns. The flower-stems vary from 3 feet to 5 feet high, producing numerous nodding blossoms 2 inches to 3 inches in diameter, and of a soft golden-yellow. It is also biennial, requiring a rich deep soil and partial shade. A native of Nepal.

WALLICH'S GIANT BLUE POPPY (*M. Wallichii*) is, perhaps, the finest of the Poppy-worts in cultivation. It is a truly handsome herbaceous biennial, remarkable inasmuch as it is one of the few, if not the only truly blue-flowered Poppy in cultivation at the present time. It

grows from 4 feet to 7 feet in height, forming a perfect pyramid, extremely beautiful in full flower, the drooping Poppy blooms, of a fine pale-blue colour and perfect in shape, being always interesting. The flowers first open at the top or ends of the branches, continuing until those nearest the main stem have opened. Although, as a rule, not more than about twenty flowers are fully open at one time, there is something fascinating about *M. Wallichii* in full bloom that attracts those not even specially interested in plants. Its curious, deeply-cut leaves, the conspicuous long red bristle-like hairs, its general habit, &c., all tend to mark it out among its fellows for special attention. It was first discovered in Sikkim by Sir J. D. Hooker, and seeds sent home produced plants that bloomed in the Royal Gardens, Kew, in June, 1852. It forms a rosette of large leaves, 12 inches to 18 inches long, deeply cut, and so brittle that,

Wallich's Giant Blue Poppy (*Meconopsis Wallichii*).

although well able to stand our winters, they are apt to be damaged by snowfalls, heavy coverings, &c. The plants naturally like a moist situation in a rich, deep, peaty soil, and partially shaded from the midday sun. It is biennial, and to keep up a stock, seed should be sown annually, and this as soon as gathered. In strong plants and from the first flowers the seed is invariably good and sound. It is an interesting and conspicuous rock plant (see accompanying figure). The varieties fuscopurpurea and purpurea are not so desirable as the type, and when allowed to grow together, spoil the fine blue of the old form. D.

5316.—Plants for a bed.—The most satisfactory system of planting an herbaceous border, to my mind, is to set out a good bold group of any one thing, keeping the tall subjects to the back of the border, with a due regard to the arrangements of colours of the various clumps

that are likely to be in flower at the same time. "Thankful" will find a good and varied choice of useful herbaceous perennials suitable for supplying cut flowers in the following list: *Achillea Ptarmica* fl. pl. (1½ feet, double white); *A. Ptarmica* "The Pearl" (larger variety of preceding, 3 feet); *A. Mongolica* (2 feet, single white, summer flowering plants, very free and useful); *Alstromeria chilense* (1 foot, colours various); *Anemone japonica* (rose) and *A. japonica alba* (white, 2½ feet, autumn flowers of great beauty); *A. sylvestris* (the Snowdrop Anemone) (1½ feet, will grow almost anywhere, flowers white, flowers in spring); *Calystegia pubescens plena* (the Double Bearbind) (3 feet to 4 feet, needs support, flowers from June till October); *Campanula persicifolia* (blue) and *persicifolia alba* (white, 2½ feet), the perennial Cornflowers (white, yellow, and blue forms are very free, 2 feet); *Chelone barbata* (scarlet); *Chrysanthemum maximum*, the best hardy Marguerite (1½ feet); *Coreopsis lanceolata* (yellow, 2½ feet, flowers nearly all summer); *Delphinium* (hybrid varieties, 3 feet to 5 feet, various shades of blue); *Dielytra spectabilis* (2 feet, early summer); *Doronicum austriacum* and *D. plantaginum* (Harpur-Crewe) (1½ feet, yellow spring flowering plants); *Gaillardia* (2½ feet, shades of yellow, orange, and crimson, very showy and useful, and with a long-flowering season); *Galega officinalis* (blue) and *G. officinalis alba* (white, 3 feet); *Geum coccineum* and *G. atrosanguineum plena* (bright-scarlet, 1½ feet to 2 feet); *Cypso-phylla paniculata* (2½ feet, very small starry flowers, borne in great profusion); *Helianthus rigidus* and *H. multiflorus major*, and several other perennial Sunflowers (yellow, 4 feet to 6 feet); *Hemerocallis* (Day Lilies) (yellow, 2½ feet); the Everlasting Peas (*Lathyrus latifolius* and *L. alba*), (4 feet, are very prolific if not allowed to seed). Of Lilies probably *L. candidum*, the Madonna Lily (white); *L. cruceum* (orange); and *L. tigrinum* are the most satisfactory without special treatment. *Lycnis chalcidonica* and *L. Haageana* (scarlet); *Malva moschata* (pink) and *M. moschata alba* (white, 2½ feet); *Matricaria inodora plena* (white, 1½ feet); the Iceland Poppies, *P. nudicaule* 1 foot (this can be had in distinct colours—yellow, white, bronze, and rose); Perennial Phloxes are very numerous, and can be had in various heights. *Pyrethrum nigrosum* (a tall, autumn flower, white, 4 feet to 6 feet); Hybrid *Pyrethrum* (double and single, about 1½ feet, are very valuable, can be obtained in any shades of colour required); *Ranunculus acemitifolius plena* (2 feet, double white, spring flower); *Rindbeckia Newmanii* (1½ feet, yellow, with black eye); *Scabiosa caucasica* (2½ feet, mauve); *Solidago* or Aaron's Rods (yellow autumn flower, several varieties vary in height); *Spirea Filipendula plena* (white, 1 foot); *S. japonica*, 1½ feet, white); *S. palmata* (2 feet, rose). Then we have Pinks, Carnations, a great variety of choice of Gladioli, from early summer flowers, like *G. Colvillei* alba, to the later-flowered hybrids of *gamlavensis*; nor should we forget the newer race, Lemoine's hardy hybrids, showy biennials, like the Canterbury Bells, and a host of hardy annuals.—F. B., *Wurchester*.

5376.—Climbing flowering plants.—You could select Honeysuckles, which are very charming growing against a wall; Clematis Jackmanii and other kinds of Clematis; Rose Gloire de Dijon, the best of all climbing Roses; Jasmines, particularly the Winter-flowering *J. nudiflorum*, which bears a profusion of bright-yellow flowers on the naked shoots throughout the winter when the winter is mild. These will all succeed in the position mentioned.—C. T.

5373.—Moss on a tennis-lawn.—It seems to me that the best remedy is to thoroughly overhaul the lawn and put down fresh turf in the places where it is needed. Your patching-up process will not make a lawn fit to play upon in the coming summer. Get some good turves, and if you are not able to do so yourself, get a competent man to lay them down. This will be far the better plan in the end and save much vexation.—C. T.

—There are two causes of Moss on lawns—viz., damp and barrenness. In your case the soil appears to be poor, and rich heavy soil should be beneficial.—E. H.

5380.—Good blue annuals.—Two of the best blue annuals that I can suggest for this special purpose are *Lupinus nanus* and the blue *Dracopis* of the annuals. The Lupin is

a very pretty and continuous blooming species. Its flowers are really blue and white, but its effect is that of a blue flower. These two things would come in at the back of the Nasturtium, as proposed; but I may say there is no truly white Nasturtium, and the nearest approach is a very poor thing in colour, not a plant to be made much of in front of a border. Two other good blue annuals that would be charming in front of the border are *Nolana atriplicifolia* and *Phacelia campanularia*. If one was not restricted to the use of annuals the old Blue Salvia and the Blue Daisy (*Agathina caelestis*) are quite two of the most beautiful things. They can be bought cheaply and planted out in May.—A. H.

— One of the best blue annuals, *Phacelia campanularia*, would probably be too dwarf, as it only grows a few inches high. It would look well in front of the dwarf White Nasturtium. *Nemophila insignis* is pretty, but will hardly last all the season. I need to have beautiful seedlings of *Viola cornuta*. Seedlings raised now will flower during summer.—E. H.

5389.—Growing Dianthus.—I presume you mean the varieties of the Chinese or Indian Pink (*Dianthus Fuldewigii*), the seed of which must be sown under glass in the early spring. You do not appear to have been very happy in your management of this very beautiful and varied-coloured flower, but avoid the dusty, pinkish colour, which may be quaint, interesting, or æsthetic, as they are sometimes called, but very ineffective in the garden. They require a good rich soil, plenty of space to develop, and careful treatment during the summer. I should pot up your little plants; keep them near the glass to prevent the growth getting long drawn. If kept in a shady place or a long way from the glass the growth soon gets drawn.—C. T.

TREES AND SHRUBS.

HONEYSUCKLES (LONICERA).

These graceful, fragrant, and beautiful plants may be made a charming aid to the flower garden or pleasure-ground. Whenever picturesque gardening is attempted they are beautiful, if isolated and allowed to ramble as tufts in their own way, while occasionally in bold rock gardening, on banks, in groups, or in tufts, they would be charming. The common native Woodbine or Honeysuckle (*L. Periclymenum*), particularly its fine varieties, the Dutch (see Fig. 1) and Late Dutch, are as beautiful as any. Both varieties bear dense clusters of fragrant red and yellow blossoms, and are vigorous climbers. The late Dutch variety blooms throughout the autumn, and hence is perhaps preferable to the

japonica (also called *L. Hilleana*) is one of the loveliest of all, being very elegant in growth and profuse in bloom. It has broad, pale-green foliage, and its deliciously-scented flowers are first white and then pale-yellow. It is an extremely vigorous grower and free bloomer, continuing in flower for several weeks in July and August. *L. etrusca*, with very sweet-scented flowers of a yellow and purplish hue, is a strong twiner, and so is the

NORTH AMERICAN L. FLAVA, the flowers of which are a rich yellow, though it requires the warm shelter of a wall. A variety of *L. flexuosa*, having foliage netted with yellow veins, is called *aureo-reticulata*. It is an elegant and effective climber, but not so desirable a flowering variety as the typical *flexuosa*. The North American Trumpet Honeysuckle (*L. sempervirens*) (Fig. 2), though usually grown as a greenhouse climber, is quite hardy enough for open walls in the south, and a very cheerful climber it is throughout June when covered with an abundant crop of orange-scarlet flower clusters, which are often borne again in September. It must have a light warm soil, and grows admirably in sandy peat. The commonest variety of it is that called minor, which blooms more freely than the type. A little known, but elegant Honeysuckle is *L. acuminata*, from the Himalayas, a tall, strong shrub with large leaves, which bears large purple flowers in pairs from the leaf axils throughout July. Besides the twining Honeysuckles, there is a group of them which do not climb, these are called Bush. They are numerous, and several are worthy of attention. The winter-flowering *L. Staudishi* and *fragrantissima* belong to this group. Though strictly non-climbers, they are usually grown against walls or trellises. Their very fragrant white flowers, sometimes produced in mid-winter, make them most desirable for the walls of a house or garden, where their fragrance may be enjoyed; or they may be grown as bushes in the open shrubbery. *L. Ledebouri* is a common Bush Honeysuckle of strong, wide-spreading growth, bearing in summer an abundance of yellow and red-tinged flowers, and, as it rapidly spreads in a graceful mass, is an admirable lawn or bank shrub. *L. tatarica* and *Xylosteum* are common shrubs, not so important as the foregoing; the first bears pink flowers, the other, a native plant, has white blossoms. G.

5392.—Cutting a Privet-hedge.—If you want a thick hedge cut it down within one foot of the ground in March. If you state the height you require it to be I will be able to give you more instructions.—P. D. D.

5435.—Striking cuttings of Golden Elder.—Cuttings 3 inches or 40 inches long of the ripened young shoots, planted firmly in the ground, will soon make good plants.—E. H.

5371.—Clematises.—The best petalled Clematises in the list I gave on page 690 are in the Jackman section. The old Jackman frequently only carries four petals, but this is not hard and fast rule.—P. U.

5374.—Cutting back Rhododendrons.—You may cut down your Rhododendrons to any height you like. You must, however, understand that the lower you cut them the harder the wood will be; consequently, the longer it will take them to start into growth. Old wood makes very freely shoots the first year and does not quite recover until the end of the third season's growth. Something depends, however, on the condition of the roots. If these are in a deep bed of natural soil the growth will be fairly strong the second year. If the plants are in a prepared bed, not more than 18 inches deep, you had better give the bed a surface-dressing of peat or suitable loam 3 inches thick to help the roots. If these materials are not available, make up a mixture of rotten turf, leaf-soil, and sand, and lay it on the bed. The end of March is a good time to cut them down.—J. C. C.

— If cut back in March they will break and get green during the following season, but the wood is harder than that of Laurels, and the buds will consequently be longer in breaking.—E. H.

5387.—Plants in Rhododendron beds.—Please avoid such commonplace things as you have mentioned. Such a position gives ample opportunities to plant the finer kinds of Heaths, which are delightful in such a position and succeed remarkably well, and you may have the pretty Dog's-tooth Violets, Grape Hyacinths, the *Hebe* (spring Star-flower), Glory of the Snow, and many other flowers. The dwarf varieties of Lily would do also, but I should plant the

various forms of Heaths. They are much neglected, and yet as charming as anything one can get in a garden. A peat bed is exactly the place for them. I have usually seen *Gladiolus brechenleyensis* in a good loamy soil, but possibly it would succeed well. It is a glorious *Gladiolus* for planting in a mass, none better—far preferable than many of the high-priced hybrids for this purpose. A good clump of this scarlet flower in the autumn is a gay picture.—C. T.

— Seeing that your beds have only a single plant of *Rhododendron* in the middle, and this only 1 foot high, you have a good space of uncovered ground to fill up. For the summer you may fill up between the Lilies and *Gladiolus*, the

Fig. 2.—North American Trumpet Honeysuckle (*L. sempervirens*).

remaining spaces, with *Lobelia* and Golden Feather, and plant a few Zonal Pelargoniums, China Asters, or Ten-week Stocks. The *Gladiolus brechenleyensis* will grow in the peat as well as the other kind. Next October, when these subjects are over, you may put in their place such bulbs as Hyacinths, Tulips, Snowdrops, and Crocuses; also a few Pansies and Forget-me-nots.—J. C. C.

5350.—Evergreen hedges.—There is nothing that associates so well with Thorns for a hedge as Privet, and if you get the oval-leaved form it is nearly evergreen, and grows quickly, and will bear clipping or cutting back in any way you like. There is certainly nothing better for filling up the bottom of your hedge quickly. The common Laurel is the next quickest-growing plant, but it resents constant clipping after a few years. As Hollies are so slow in growth, my choice would either be the Privet or the English Yew. The latter makes a neat hedge, and is thoroughly wind-proof.—J. C. C.

5177.—Tuberous-rooted Begonias.—If the tubers are large they may be successfully divided, but each piece must have one or more "eyes" or they will not grow. The best time to divide them is just as they are on the point of starting. Cut them clean through with a sharp knife, and lay the pieces on a dry shelf for a day to heal the cuts thoroughly. Then place them singly in small pots of sandy soil, place in gentle heat, and water very sparingly till they are well in growth. I do not consider divided bulbs equal to whole ones; but in one way it does good, as the stems will be stronger, and with good culture they will do very well.—B. C. R.

5351.—Ashes for the garden.—Nothing better, especially if the soil of the garden is naturally heavy or damp. Even otherwise good coal-ashes contain a certain amount of manurial properties. All you have to do is to spread the ashes on the soil and dig it in.—B. C. R.

5370.—Corrugated iron for stages.—Only the upper surface of the iron need be lime-washed, the other is of no consequence. The lime should be fresh and hot.—B. C. R.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of *Gardeners' Flowers* and good fruits and vegetables for drawing. The drawings so made will be engraved in the next number and will appear in due course in GARDENING ILLUSTRATED.

Fig. 1.—Flowering spray of Dutch Honeysuckle.

other. In Continental gardens it is sometimes the custom to train common Honeysuckles as low standards for borders, and when in flower their appearance is pleasing. *L. Caprifolium*, also found wild in England, makes a beautiful garden climber, and is a good deal like the native kind form. A very charming climber is *L. flexuosa*, from Japan. It can always be recognised by its dark purple stem and very hairy purple-stained leaves. The flowers are purplish-yellow and very sweet-scented. *L.*

INDOOR PLANTS.

5346.—Treatment of Chinese Primulas.—These are among the easiest of all greenhouse plants to manage, and at the same time some of the most useful, flowering continuously for six months at a stretch, and often longer still. To obtain nice plants in bloom by Christmas or even earlier, the seed should be sown early in April, though for late or spring flowering a month later will do. If large plants in 6-inch or 7-inch pots are wanted better sow in March. Any well-drained pan or box will do to raise the plants in, or pots may be employed, though these dry too quickly to please me. The best soil is a mixture of fine loam and leaf-mould in equal parts, with plenty of sand and a little sifted Cocoa-nut-fibre to keep it open; drain well, press the soil gently to an even level, sow the seed, water in well, and just cover the seeds with a little sifted leaf-mould (or Cocoa-nut fibre will do almost as well) mixed with a fourth of sand. Place in a temperature of about 60 degs. (I have often raised the plants capitially in an unheated house in May and June), and keep regularly moist and shaded from sun. Prick the seedlings off when fit, and pot them first into small 60 pots, and afterwards into 4½-inch or 5-inch size. Grow on till October in a cold frame, lightly shaded, but with plenty of air, then house. These charming plants are much hardier than many suppose, and when hardily reared will endure several degrees of frost uninjured.—B. C. R.

5385.—Treatment of Carnations.—The plants now in small pots should be repotted into 6-inch ones in February. These are not anything too large for single plants of "Malmaisons." They would do very well in an unheated Rose-house if the plants are placed near the glass-roof and kept clean. Some of my last year's layers of Malmaisons are so large that they will be potted to flower in 7-inch and 8-inch flower-pots. The pink-flowered one is stronger in growth than the blush.—J. D. Y.

5343.—Heaths after flowering.—Harden the plants off slightly (especially if they have flowered in a warm-house in the winter), and give rather less water than usual for a time, then prune them moderately, cutting out most of the weak spray, and shortening the strong shoots that have flowered to half or a third of their length. Afterwards keep close in a warm house or pit and not the syringe freely overhead, but give water at the root only, so as to prevent the soil becoming really dry. As soon as they have fairly "broken" again give more water and thin out the shoots a little, if necessary. When these are an inch long give the plants a moderate shift, using good sandy peat made quite firm. Keep moderately warm and close for a time until well in growth again, when the best place for the plants of most varieties is standing on ashes in the open air; at least, until the middle of September. The hard-wooded kinds will not bear so much pruning as those of a comparatively soft growth, such as the well known *E. hyemalis*.—B. C. R.

— Pick off all dead flowers, and shorten back all long shoots. The soft wood Heaths such as *Hyemalis gracilis*, *Melanthera*, &c. will be benefited by a little warmth after pruning, till they break into new growth. When the young shoots are fairly started the plants may be repotted.—E. H.

5353.—Aspidistras in pots.—Doubtless the reason why these plants are not making such strong healthy leaves as heretofore is owing to the plants having exhausted the soil in the pots in which they are now growing; the only remedy for this is to repot the plants into large flower-pots. Good yellow loam, leaf-mould, and decayed manure is the compost they thrive best in, a little coarse sand added serves to keep the compost open. If it is undesirable to have the plants in larger flower-pots than those they are now grow in they may be broken up, and the plants can be replanted in smaller flower-pots. They are easily grown plants.—J. D. E.

— Your plants are evidently in a starved condition, and require to be repotted. Give them a few doses of weak guano or root-water, and in a month or six weeks' time shift them into other pots (clean and dry), 2 inches or 3 inches larger across the rim. Use a mixture of loam (or good garden soil) with a third as much leaf-mould, and some sand; drain the pots well, and make the soil quite firm.—B. C. R.

— The leaves will get smaller when the roots are cramped. To obviate this divide and repot or shift into larger pots, or give liquid-manure.—E. H.

HERBACEOUS CALCEOLARIAS.

These plants come in capitially to succeed the Cinerarias. The flowers in a cut state do not last a long time, but the plants when used for the decoration of the greenhouse or rooms, and placed so that they receive a fair amount of light, are very showy and most interesting, as the colours vary much when seed is procured from a good strain. The habit of growth, compared to what it was a few years ago, is also so much improved by careful selection as to render this plant much more desirable in every way. The accompanying engraving shows an excellent type of plant—dwarf, bushy, and one mass of bloom. To have the plants in full flower by the end of April or early in May, the seed should be sown thinly in large pans about the first week in June, using a compost of half peat and leaf-mould, adding to this a plentiful supply of silver sand, the whole passed through a fine sieve. Sow the seed thinly. If the soil is moist no water will be required for a time; but when water is required it should be allowed to soak through the bottom of the pan until the whole mass is thoroughly moist, care being taken not to wash the seed off the surface. Thoroughly drain the pan by filling it three-parts full of crocks, and over these place a layer

of 2½ inches in diameter, using rather more loam and not sifting the soil so fine; return the plants when potted to the frame. By keeping tho

FRAME UNDER A NORTH WALL during the summer months shading is dispensed with—an important item in the culture of these plants, as it often happens that when the frame is placed in a sunny position sufficient moisture is not maintained without the plants, and they fall a prey to green-fly, which, if not quickly eradicated, soon cripples the plants to such an extent that they hardly ever retain that vigour which is essential to success. During the summer months a damp atmosphere within the frame must be preserved, the plants standing upon a thick bed of coal-ashes. As soon as the roots reach the sides of the pots, and before they are in the least pot-bound, shift them to a larger size, according to the size of the plants, until they are in their flowering pots. Those plants in 6-inch pots are the most useful. After the first shift the soil may have more turfy loam and a small quantity of partly decomposed horse-manure added to the previous mixture, and leaving out some of the peat. For the final potting, which usually takes place in January, when the plants are in their winter

A good type of Herbaceous Calceolaria.

of rough leaves, pressing the soil firmly in the pan and maintaining an even surface to within half an inch of the rim. Upon this surface sow the seed thinly, gently pressing it down and covering the whole with white sand, which induces a quick rooting of the plants. Over the surface of the pan place a square of glass, covering the same with Moss, which assists in retaining the moisture in the pan; or a piece of slate, which preserves the moisture better than glass, may be placed over the top of the pan. Place the latter in a cold frame behind a north wall. The seed will quickly germinate, and as soon as the seedlings appear above the soil admit air by slightly tilting the glass on one side and removing the shading, and if slates have been used substitute glass. As growth progresses remove the glass entirely, and give a little air to the frame. When the seedlings are large enough to handle transplant them carefully into other pans about 1 inch apart, using the same kind of soil, with the addition of some loam, sifting all fine as before. Return them to the frame, and keep close for a few days until the roots have taken to the new soil. Gently dew the plants overhead with tepid water, and admit air gradually as growth proceeds. When the leaves touch each other the plants will be ready for their first shift into

quarters, should be well prepared. About the middle of September, or sooner, should the weather be cold and dull, they should be placed where they will obtain more light and a little sun. A cool-house from which frost is excluded suits admirably. They will need but little fire-heat during winter.

AS THE SPRING ADVANCES and the pots become filled with roots a little weak sheep or cow-manure three times a week will be very beneficial. Early in March the flower-stems will begin to develop above the foliage, and they will each require the support of a small stake. When in flower in April and May a slight shade from hot sunshine is required. Mind, if the plants are allowed to become pot-bound or ever-dry at the roots they seldom regain their natural vigour. When there are any signs of green-fly on the leaves smoke the plants carefully with Tobacco in the evening, and again in the early morning, as the second application will generally effectually destroy any that may be left alive from the first fumigation. After this give the plants a good washing with the syringe. B.

Original Flowers for Christmas.—There are few flowers that will open their blossoms in the open air at Christmas. The Christmas

Rose (*Helleborus niger*) will do so. The best variety is that with pinkish flowers named major. It is also grown in some districts under the name of *altifolius*. There is a pretty variety later in flowering, but with whiter flowers, grown as *angustifolius*. Under glass the best white flowers are the handsome *Arum Liliæ*, Roman Hyacinths, Double and Single Dutch Hyacinths, Double and Single White Azaleas, *Eucharis amazonica*, and the tall spikes of white-flowered *Callianthes*.—J. D. E.

5368.—**Plants for a greenhouse.**—You could begin with a few good vigorous-growing Ferns, such as *Pteris cretica*, its variety *abnormalis*, *P. tremula*, *Onykelium japonicum*, *Cyrtodium falcatum*, and *Adiantum cuneatum*. These are not at all troublesome to manage, and may be brought in, when so desired, for room decoration. Then you could have *Aralia japonica*, *Aspidistra lurida variegata*, both good easily-grown things, *Cytisus racemosus*, producing a wealth of yellow flowers, bulbs in variety, Hyacinths, Tulips, &c., *Campanulas*, as *C. carpatia* and the white *C. isophylla alba*, or *C. muralis*, very charming in a basket, Zonal Pelargoniums, and Ivy-leaved varieties particularly, the salmon rose-coloured *Mme. Crousse*, *Cinerarias*, Chinese Primulas, the sweet-scented Tobacco-plant (*Nicotiana glauca*), a very useful pot-plant, bearing a profusion of large ivory-white, sweetly-scented flowers, *Maréchal Niel* Rose planted in the border, and the graceful *Grevillea rubra*. Amongst flowering plants I should rely chiefly upon the Pelargonium, which is very easily grown, as possibly you are aware, and there are a number of splendid varieties, both single and double.—C. T.

5348.—**Luculia gratissima.**—After the plants have all been pruned back young shoots will break out, and when the smallest of these are 3 inches or so long take them off with a sharp knife, cutting a small heel of the old wood with each cutting. Dibble in pots of sandy peat, a layer of sand being placed on the top. Cover the cuttings with a bell-glass, and shade from bright sunshine. Wipe the bell-glass dry inside every morning.—E. H.

—The cuttings should be inserted in March, in well drained pots of sandy peat, sifted with pure sand, covered with a bell-glass, and placed in a warm-house or propagating-pit. They must never be allowed to flag, or they will fail to root. Of course, the condition of the cuttings is a matter of considerable importance.—B. C. R.

5342.—**Gloxinias from seed.**—These plants are very easily raised from seed; but the *Gloxinia* is a hot-house plant, and the seed, which is small in size, should be sown in fine soil, and slightly covered with the finest particles, which should contain a good deal of white sand. The seed vegetates most freely if sown in pots or pans, and they ought to be placed in the forcing-house or plant stove, and the seed will vegetate all the more freely with a little bottom-heat. When the small plants have formed the first leaf or two after the seed-leaves they may be pricked out into other pots or pans, and after making good growth they may be planted singly in flower-pots, and if the seed is sown now and the plants grown on freely in a hot-house, they will flower well during the ensuing summer and autumn, and well into the winter.—J. D. E.

5329.—**Plants for a small greenhouse.**—The fact that the window of a sitting-room opens into this greenhouse would not be sufficient to keep the frost from it in severe weather, but with due care Violets might be grown well in it, and many other plants, such as Auriculas, Roses, and Carnations. These, however, will not flower in winter except in warmth, but they might do well in spring and autumn. Climbing Roses, such as *Niphetos*, William Allan Richardson, *Gloire de Dijon*, and *Reine Marie Henriette*, may be planted in the border, and this edge with English Ferns, especially *Hart's-tongue* (*Scelopendrium vulgare*), *Asplenium Adiantum-nigrum* (sometimes called French Fern), and Holly Fern (*Polystichum lonchitis*), which are all evergreen, and therefore are decorative in winter as well as summer. Small hot-water arrangements for heating are now so attainable that "B. B." might easily keep the frost out, and have more flowers in winter. Bulbs of many sorts can be grown, however, without heat—Tulips, Narcissus, Hyacinths, &c., and Wallflowers. Forget-me-not and *Polyaroses* used to make a spring show. The Zonal Begonias can be grown here in summer.—I. L. R.

HOUSE & WINDOW GARDENING.

CUT-FLOWERS IN THE HOUSE.

NARCISSUS.

WHERE cut-flowers of these are desired they should be planted in bold groups on borders, in beds, or on Grass sheltered by hedges or shrubs. The first crop of blossoms can be obtained from pots or boxes in the greenhouse, and these will be quickly followed by fully formed and bursting buds in sheltered and sunny places. These buds will open large, fresh, and fair if placed in pots of water in a warm greenhouse or a sunny frame or window. In cutting Daffodils or Narcissi for indoor decoration, cut the flowers when the buds are opening or even

OUR READERS' ILLUSTRATIONS: *Narcissus biflorus*. Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. J. R. Pearson, Chilwell, Notts.

just before, and let the stalks be long, as the flowers group better with long stalks. Do not cut the leaves of choice kinds, but use the foliage of common sorts with choice flowers. Put each kind in a separate glass. Put together as many of the same kind as you like, but always avoid overcrowding. Amongst the many kinds of Narcissus useful for cutting, the creamy white, *N. biflorus* (here figured) is valuable. It is one of the easiest of all kinds to naturalise, spreads rapidly and flowers freely. B.

5311.—**Room plants nipped by frost.**—These plants should not be placed in strong heat or sunshine, but be syringed overhead in a moderately warm place when frost-litten. But by this time they will have probably partially recovered, and will be useful next year although their beauty is spoiled for the season. The *Callus* must be kept safe from frost until the end of May, and then turned out of their pots to gather strength, in a rather shady border, until September; placing them in good soil, and giving them an occasional drenching with water or liquid-manure in dry weather. They should be potted up in September, and brought on, in slight heat, to flower by Christmas, giving them abundance of water, but carefully sheltering them from frost. The Hard-foot Fern will recover best in the damp warmth of a fernery, where it will throw out new fronds in time; and the *Freesias* should be kept in their pots until their green has quite turned to brown, and repotted in July; then placed in a warm sunny position out-of-doors to start. The best way to save room-plants from the frost is to remove them at night to a heated greenhouse; if this is not feasible, take them away from the windows, and place them together in a corner near the fireplace, covering them at night with several newspapers, which are light, but keep out a good deal of frost. During intense cold, the fire should be banked up and left burning, with a guard on; a lamp, if kindled on the floor between the plants and the window, prevents the air freshening (the current of hot air rising between) and if the

lamp be placed in a metal tray it will be safe from accidents. A bath-room, where hot-water pipes are constantly warm, is a good night refuge for plants in frosty weather; but if placed out of all draughts, and well covered with newspaper, they are safe in ordinary weather. This covering should not be removed until after the room has been aired and brushed out in the morning; a most dangerous time for delicate plants in pots, or during the prevalence of cutting winds.—I. L. R.

5386.—**Window boxes.**—The window-boxes should be made of wood, painted green or other suitable colour, which may be left to individual taste, but avoid anything conspicuous. Each box should be about 1 foot in depth, and have two or three good-sized holes in the bottom for drainage. As regards the breadth, the box should fit the window, and a local carpenter will give you an estimate. An ordinary window-box should cost little, but it is better to have them substantial in the first place. If covered with virgin Cork they will look less formal, but this is a matter for you to decide. In my own case I have little separate boxes to fit into the side windows, but perhaps a continuous box, so to say, would be better, as then you could get a regular fringe of flowers. Fill up with ordinary soil, such as used for Pelargoniums and greenhouse plants generally. Put in a few large crocks in the bottom, and then some flake leaf-mould to prevent the fine soil from running down and choking up the drainage. You must make good use of the Ivy-leaved Pelargoniums, which are numerous; but I like the salmon rose-coloured *Mme. Crousse* as well as any. It is a very charming variety, and will bloom throughout the summer and until cut by frosts. There is really nothing better than this class of Pelargonium for the summer, and for growing up the sides of windows you have the quick-growing Virginian Creeper, particularly the variety *marialis*, the leaves changing to fine colours in the autumn, or you can make good use of the annual *Convolvulus*, very pleasing with their gay-coloured flowers. Ivies, particularly the pretty variegated kinds, could be also trained up the window, or the gay yellow-flowered Canary Creeper, which is a remarkable free bloomer, with its pretty light-green growth and bright-yellow bloom. Then you may make use of the climbing *Nasturtium*. To fill up the centre of the boxes you may use *Lobelia*, *Musk*, *Tuberous Begonias*, *Night-scented Tobacco*, *Zonal Pelargoniums*, *Fuchsias*, and similar things.—C. T.

—Although the metal boxes are lighter and occupy less space, I consider the wooden ones superior in several respects. They are easily made of flooring-boards, which run to 6 inches to 6½ inches wide, and about ½ inch thick—these for the sides; for the bottoms use the same, or those 9 inches or 10 inches by 1 inch thick are sometimes more convenient. The front can be ornamented with either the glazed tiles now so common or pieces of virgin Cork nailed on. Make them the full width of the sills, so as to have two or three rows of plants instead of one if possible, and a depth 6 inches (inside) is quite sufficient. For bow windows three boxes will be necessary, each made to fit its place as nearly as possible. Bore five or six 1-inch holes in the bottom of each for drainage, and place 1 inch of broken bricks or ashes in the bottom, with some rough siftings over. Soil, three parts of good loam to one of leaf-mould or well-decayed manure, some sand, and a little soot. The best plants are ordinary "Geraniums," *Fuchsias*, *Calceolarias*, *Margarites*, *Begonia*, *Lobelia*, &c.; for the front Ivy-leaved Pelargoniums and *Fuchsias*.—B. C. R.

5382.—**Heating a sitting-room.**—Why not heat your sitting-room at night with one of the oil-stoves, like *Toopoo's* or *Rippingille's*, either of which would suit you admirably, as if there should be any smell to them the fumes could escape up the chimney? It is when there is no escape for the injurious fumes that they are objectionable. The main point, however, is, in such a case as yours, to light the stoves only in frosty weather. Place a thermometer on one of the pots nearest to the window, and when it gets down to 35 degs. light the stove and put it out again when the same instrument indicates 45 degs.—J. C. C.

—The City of Urbana has a sitting-room of fair size with an oil-stove. It is surprising the perfection

to which the oil-stove has been brought in recent years, and when the wicks are kept properly trimmed and the bowl, so to say, not too full, no small arises, except perhaps a little when first lighted. Light the stove some time before the room is aired, and if stood in the centre, the whole place will soon get comfortably warmed. An oil-stove in a bedroom or bathroom is of great service.—C. T.

— I should say that one of the numerous stoves on the slow-combustion principle, and preferably one cased with terra-cotta or porcelain, would be very suitable, as they give off a nice gentle warmth for many hours without attention, and at a very small cost for fuel. One of the small hot-water apparatuses, heated by either gas or paraffin-oil, such as are advertised, would do equally well if fixed in the window beneath or near the plants. These require next to no attention, and give off a perfectly steady heat.—B. C. R.

DOUBLE-FLOWERED FUCHSIAS.

Fuchsias make admirable window-plants, and can be so grown to great perfection. Though opinions may differ as to whether single or double-flowered Fuchsias are the more beautiful, there can be no doubt whatever that the double flowers are admired by many, and the demand for them is, I think, greater than for the single forms; consequently among the new varieties sent out within the last few years there is a preponderance of double-flowered kinds. Some of the rather doubles were rather apt to run up tall, and were therefore not so well suited for growing in the shape of little bushes useful for rooms as many of the single ones; but this cannot now be urged against them, as the accompanying illustration of Frau Emma Tejfer will show. Few classes of plants had themselves to so many different modes of treatment as the Fuchsia; for instance, they may be grown as bushes, pyramids, or standards, employed for covering roofs and furnishing pillars, or for beds in the open ground. For all these varied purposes suitable varieties with double blossoms are to be found among the numerous forms now in cultivation. These double-flowered Fuchsias are not so popular with the market grower nor for exhibition as the single forms, for, owing to the blooms being much heavier, they are far more liable to drop when shifted about than those of the single-flowered varieties are. In making a selection of the best double-flowered Fuchsias, I should be inclined to give a place to the following with light-coloured corollas:

FRAU EMMA TEJFER, a free-growing, freely-branched variety, with a very large corolla, of a kind of pinkish-white, deeper towards the base of the petals. The sepals of this are coral-red, and, in common with many large-flowered varieties, they do not appear of sufficient size for the huge corolla. The blossoms of

MISS LACEY FINNIS (a spray of which is figured on page 688) are something in the way of those of the last, except that the corolla is pure-white and the plant is not so free in growth. This when first sent out (about sixteen or seventeen years ago, I think) attracted a large amount of attention. It makes a good pot plant, but as the branches are weak and the flowers heavy, ample support must be afforded them. It is largely grown for Covent-garden-market.

MME. JULES CURETIN forms a fine large specimen and is suited for furnishing a pillar, as it grows quickly, while the flowers are bold and effective. The corolla is large and pure-white, and the sepals are more conspicuous than in either of the preceding.

MOLESWORTH is a good variety for any purpose, and one that has become popular with our market growers. The corolla is large and pure-white, while the bright coloured sepals are of a proportionate size and reflex in a very pleasing manner.

BUFFON, a somewhat upright-growing variety, is noteworthy from the peculiar pinkish-tinged corolla. The last variety to mention of those with white corollas is

DUCHESS OF BOWSWORTH. Of this I have had but a limited experience, but still sufficient to lead me to think it will turn out one of the very best of this section. It was introduced by Mr. George Ruddle, so well known in connection with the Fuchsia, and was announced as a cross

between Molesworth and Mrs. E. G. Hill (one of Lemoine's varieties). It is a large bold flower, while the petals are unusually thick and wax-like.

Of dark-flowered varieties there is a great number, many of which differ in little else but name from each other, though of course there are some very distinct forms:—

AVANCEUR, which was sent out about twenty years ago, is still one of the best, the habit being good, while the flowers are freely borne.

PHENOMENAL flowers profusely when small, yet the blooms are, with one or two exceptions, among the largest of all Fuchsias. The corolla of this is of a deep violet-purple colour, marked with rosy-crimson at the base. It is a good variety for growing in the shape of little bushes.

NOUVEAU MASTROINTE has a large purplish corolla, flaked more or less with red. This latter feature renders it when well marked very attractive.

CANTIE LEON TILSTON is notable from the closely-packed corolla being of a deep bluish-purple, without markings of any kind. The habit of the plant too is very good.

LA FRANCE has large, well-reflexed sepals and a distinct tinted corolla, which has been described as blue, and though a long way from that colour it is very distinct shade.

SIR GARNET WINSLEY is a good variety for any purpose, with a large plum-coloured corolla.

GUSTAVE FLASHERT, one of the newer French varieties, is of good habit, free-flowering, and

it received a certificate from the Royal Horticultural Society in 1875, but it is now not much grown. About twenty-five years ago a variety was sent out under the name of Norfolk Giant, that attracted a good deal of attention from the size of its flowers, but it was much inferior to Champion of the World, although from the many points of resemblance there is, I should think, but little doubt that this last was a seedling from the older one. Of light-flowered Fuchsias, that is to say those with white tube and sepals and coloured corolla, there are, as far as I am aware, none with double blossoms. The Fuchsia is a good illustration of the varying fashions in flowers, for from 1880 to the present time only three garden varieties have been noticed by the Royal Horticultural Society—viz., Mme. Galli Marie 1880, Mrs. Randle 1883, and Dorothy Fry 1889, while in the ten years previous to that no less than forty-two varieties received certificates. H.

5301.—**Creepers for a window.**—The Tropaeolum family undoubtedly furnish the prettiest window creepers, having both bright flowers and neat foliage. Tropaeolum ram-ricense is one of the best for this purpose, bearing masses of yellow flowers in luxuriant sprays, if well cultivated. Seed can be put in during March out-of-doors, unless in a very cold situation, when it may be raised in a pot inside the window, and planted out in May. Tropaeolum Ledebianum, too, in several handsome varieties, with brilliant scarlet flowers, is very

OUR READERS' ILLUSTRATIONS: Double-flowered Fuchsia "Frau Emma Tejfer." Engraved for GARDENING ILLUSTRATED from a photograph sent by Miss Helen, Hamstead, N.

especially noteworthy from the corolla being of a very distinct lilac-mauve tint. We have had two or three of this class lately from the Continent, another being

OTAVIE FROUILLÉ, a good deal like the last, but with more of a rose tinge in the corolla.

CHAMPION OF THE WORLD, a gigantic flowered variety, whose massive corolla is of an intense dark-purple. This does not bloom so freely as many others, and the flower-stalk is of unusual length, so that it is useless for blooming in a small space, but as a pillar plant in the conservatory or in some such position it will often prove to be one of the most striking of all Fuchsias. This variety is by no means new, as

suited for the purpose, and can be sown at the same time as the Canary Creeper. An twiler to hung from the windows the Ivy-leaved Pelargonium ("Geraniums") are very useful, especially such free-growing varieties—Mme. Crousse, Mme. Thibaut, and Souvenir de Charles Turner. These can be bought now as small plants, repotted, and pinched back, if straggling; they will then be ready by put out at the end of May, when they should be covered with bloom.—I. L. R.

—Original name of the Ivy-leaved Pelargonium in variety, Tropaeolum Ball of Fire, Fuchsias of drooping habit, such as Mrs. March, single flowers, and Lobelias of the double type, some of the very best plants for this purpose.—H. C. H.

ORCHIDS.

COCLIODA VULCANICA.

This is the plant which I have before brought to the attention of my readers under the name of *Mesospidium vulcanicum*, but that given above appears to be the one most recognised now. It is a great beauty, and well deserves the attention of everyone. The flowers are of a bright rosy-carmine. I see the Messrs. Veitch quote its discovery many years ago by Dr. Spruce, the German botanist, and I have always been under the impression that Spruce was a native of Yorkshire. The plant appears to grow at a great elevation, between 10,000 feet and 11,000 feet above the sea being given as its range. It is one of the beautiful small-growing kinds which every amateur should possess, being a fine companion plant for many of the cooler *Ophroglossum*, and its gay colour is a very attractive foil for the whites which are so prevalent in the last-named genus. These plants were formerly included with the *Ophroglossum*, but Lindley had established the genus *Cochlidia* upwards of fifty years ago. These Orchids should be kept in a cool-house and in a shady part of it, and they must be well drained, for they like an abundance of water during the growing season. For soil use peat-fibre and Sphagnum Moss in about equal parts, pressing it down firmly and elevating the plant upon a cone-like mound above the rim of the pot; but do not use much soil in potting, these plants do not like it, for the species grow generally amongst the erupted lava of the volcano of Tunguragua, from which it was introduced by Mr. Backhouse, of York, little over twenty-one years ago. One or two other plants of great beauty are also included in this genus. "Miss Chisholm," who has caused me to write this article, sends me some fine examples of this species, which shows that she has just the sort of accommodation which the plant requires, may add the following to her collection with the greatest confidence: *C. Ruziziana*, which is a handsome species introduced some two or three years ago by Messrs. Limon, of Brussels, and Messrs. Charlesworth and Shuttleworth, of Bradford, and which has not yet become thoroughly established in our collections. *C. rosea* is another species well deserving attention; it is a little less bright in colour than *vulcanicum*, but everywhere sought after when it was grown under the name of *Ophroglossum roseum*. The above three species should be grown by all amateurs, therefore; little expense in their culture, they produce long spikes of gay flowers which last a long time in full beauty. MATT. BRAMBLE.

ONCIDIUM LURIDUM.

This is a plant which is widely dispersed over the West Indian Islands, and of which "Mr. J. Ranko" sends me a specimen which has rotted off at the base. This I should say arises from excessive moisture with a short supply of air. This *Oncidium* was known to Linnaeus, and has been an inhabitant of our gardens for over seventy years. "J. R." wishes me to state the kind of flowers it bears, but this I would rather not do because the varieties are so numerous that I might be altogether misleading. Suffice it to say, a good variety of this plant is very handsome, and as your friend brought them home personally you must give him credit for having obtained a pretty variety. The plants naturally grow in the shade, and in very hot and damp situations, and therefore require similar treatment when under cultivation, but at the same time they need a good circulation of air. Indeed, this is a point that is quite ignored by some growers; they give any amount of heat and moisture and they exclude air. The plant should be well drained and elevated upon a cone-like mound of good peat-fibre, mixed with Sphagnum Moss. It should be placed in a shady position, and during the summer season have an abundant supply of water. The good drainage before mentioned will quickly carry this away, but in the winter the plant having no bulbs must be carefully watered from time to time to keep the thick leaves from shrivelling. This will be required very seldom, and so that not much water is necessary this time of year, and in giving too much arises the cause of "Mr. Ranko's" failure.

COELOGYNE LOWI.

I AM asked by "J. J. Tilley" to give him some information as to the treatment this plant requires to grow it successfully? It is better and more correctly known by the name of *C. asperata*, but it is a beautiful species under whichever name it is grown. The plant was imported just upon fifty years ago from Borneo by the Messrs. Low, of Chaptin, and was named *Lowi* by Paxton, but Lindley had named it *asperata* before. It remained a very scarce plant under cultivation for a great many years. Why that was I do not know, for it is one of the commonest Orchids in the Indian islands, where it is found growing upon trees in swampy ground in the neighbourhood of streams and also in the shade. Some two or three years ago very large quantities of this species were imported from time to time, so that if the plants were properly treated there should now be an host of grand specimens in the country. Yet my memory does not call to mind many of them. There is one, I know, in Sir Trevor Lawrence's collection, which is under the care of Mr. White. This plant is thriving very vigorously. *C. Lowi* is a strong, hoist-growing plant, with oblong, lanceolate, dull-green leaves, some 18 inches or 2 feet long. It bears a raceme about a foot in length, bearing some dozen flowers 3 in. across, which are creamy-white, having a bright orange-coloured lip, margined with cream colour. The

Flowering spray of Double Pheasant "Lucy Finnis."
(See page 687.)

plant is best grown in a pot, which should be well drained, and as it delights in a little loam a thick layer of living Sphagnum should be placed over the crocks in order to keep the drainage in good, open order. For the compost use a mixture of peat-fibre and Sphagnum Moss, adding a little light loam, from which a greater portion of the soil has already been beaten out. It requires ample pot-room. The plant should be kept well elevated above the rim of the pot in the summer season. When growing it requires an abundance of water, but during the winter months just sufficient to keep the bulbs and leaves in healthy condition will be all that is necessary. In the spring of the year, when the roots and growths begin to appear, the plant, which should have been resurfaced or repotted some time previously, should have an extra amount of water given it. It is an Orchid which enjoys a vast amount of heat, without which very few flower-spikes will be seen; therefore, grow it in the warmest part of the East Indian-house, keeping the atmosphere well charged with moisture. The flowering season is usually in June and July. MATT. BRAMBLE.

DENDROBIUM LINAWIANUM.

This species is an old inhabitant of our gardens, having been introduced some seventy years ago; but it does not appear to have been imported since, for no localities are recorded as yielding the plant. The flowers sent by "T. Murray" are of good size and pleasing appearance, the

sepals and petals being bright cherry-colour in the upper half, passing to white at the base; the lip also is white at the base, tipped with rich magenta. This *Dendrobe* was grown before 1860 under the name of *D. moniliforme*, but when the true moniliforme came to hand from Japan it was found to be a white species and of a very dwarf habit, so that another name had to be found for the Orchid now under consideration, which, indeed, looks more like *D. nobile*, and when grown into a good specimen it is equally pleasing. It is a plant with clavate bulbs, growing some 18 inches high, requiring the same treatment in all respects as *D. nobile*. When the situation that this plant grows in comes to be known we may have some new species introduced. MATT. BRAMBLE.

5347.—**Early Lily of the Valley.**—The only way to get early blooms of Lily of the Valley when there is nothing besides a garden frame to grow them in would be to pot up the crowns as soon as they can be obtained in the autumn. About Christmas get some fresh stable-manure, and prepare it by allowing it to heat a little until the rank steam is thrown off; then make up a hot-bed and place some Cocoa-nut-fibre-refuse or some such material over the manure into which the flower-pot containing the roots may be plunged. Care must be taken to allow the violent heat to subside if necessary, as it can easily be violent enough to kill the plants. Cover up the glass lights with mats or sacking if the weather is frosty. The leaves and flowers grow up together this way; when forced in a strong heat, but without bottom-heat, the flower-spikes have a tendency to come without the leaves.—J. D. E.

5391.—**Constructing a propagator.**—You appear to have grasped the idea of making a propagator very well. Your pan for the water is, however, too deep by half. It should be only 1 inch deep, and then only half filled with water, as the more water there is to heat the more oil you must burn to keep up the temperature. Moreover, the more water there is in the pan the more condensed moisture you will get on the glass, and which you will find troublesome. You do not want a tin chimney to carry off the fumes if you manage the lamp properly and do not allow it to smoke. If the top of the lamp is 1 inch from the pan that is sufficient.—J. C. C.

5366.—**Manures for Cinerarias and Calceolarias.**—For these and most other plants of this kind there is, after all, nothing to surpass, if to equal, a weak clear infusion of horse or, preferably, sheep-droppings given once or twice a week after the pots become well filled with roots, with a very little soot occasionally as a corrective. Failing the above, as good plants as anyone could wish to see may be grown by mixing a proper quantity of Thomson's Vine and Plant Manure with the soil when potting, and afterwards giving weak solutions of sulphate of ammonia and soot alternately every week or ten days.—B. C. R.

—A good compost for these is four parts good loam, one leaf-mould, one decayed manure, and some coarse white sand. Bone-meal added gives a more vigorous growth and finer flowers.—J. D. E.

5341.—**Wireworms.**—Wireworm are the larva of a click beetle; but as there are many species of click beetles, the larva of most of which may be classed as wireworms, it is difficult to say to which species any particular wireworm may belong. According to the best authority the eggs of the click-beetles are of a yellowish-white colour and are very small, almost invisible to the naked eye. The larva grows very slowly, usually taking five years to arrive at maturity, and all these years they are living upon vegetables, working their way into a vital part and destroying much more than they can eat. The wireworm is a terrible pest to both farmer and gardener, and if some one with leisure would devote a few years to the study of this subject and then tell us all about its history, and the best means of getting rid of it, he would be a national benefactor. Judging from the habits of the insects the best means of getting rid of them is to continually harass them by frequently stirring the soil, and by the application of such substance as salt, soot, and lime, freely intermixed with the soil.—J. D. E.

THE KITCHEN GARDEN.

CABBAGE LETTUICES.

THERE are many kinds of Cabbage Lettuces, of which Tom Thumb may be taken as the type, which do not grow more than 4 inches in height, and a large number of heads are produced on a small area. Cabbage Lettuces, on account of their compact growth, are very valuable for winter use, as they can be well accommodated in shallow frames or hand-lights.

SEED may be sown from February to September. The earliest sowing should be made in boxes or pots filled with light soil, and these should be placed in a little heat to germinate, and

Cabbage Lettuce "Large Bossin."

for the seedlings to grow for a time. A very little seed, if good, will be found enough to produce a great many plants. It is a great advantage to keep the young Lettuce plants up near the glass to keep them short and robust in habit, as when drawn up weak and spindly they are useless. Transplant the young plants before they become too crowded, and early in spring a special frame or two may be set apart for them, or they may be grown to a useful size between Potatoes and other early vegetable crops in frames. About the end of March will be quite soon enough to sow the first lot of seed in the open ground, and from that time onward a little seed should be sown every three weeks until the end of September. By adopting this plan

A CONSTANT SUPPLY of succulent produce can be kept up. Those last sown at the end of September will not produce plants of any service that year, but they will winter in the open air if the weather is mild, or, better still, under a little protection, and if planted in a good position in February or March they will produce useful heads before the spring-sown ones are ready for use. These Lettuces will grow anywhere in a rich, well-tilled soil, and in an unshaded position. It is not often necessary to plant a very large number of them in any private garden, as small quantities coming on in succession are the most acceptable. Winter crops do best on south borders, and when the weather is very severe a quantity should be lifted and planted in frames or under hand-lights, or protectors may be put over them where they stand. Of varieties there are many which vary much in size, the larger growing kinds being best adapted for summer culture. Summerhill and Marvel are good kinds for summer, and so is the large Bossin Cabbage Lettuce (here figured), one of the finest large sorts, sent out some years ago by Messrs Vilmorin, of Paris. Early Paris Market is a very fine spring kind. All the Year Round is what its name implies—a good sort for summer or winter. Stanstead Park and Hardy Green Hammersmith are very hardy and excellent kinds for winter use; and there are also several comparatively new varieties that are said to be excellent, and may be worth a trial for the sake of novelty; but the list of well-tried kinds here given are quite sufficient for all ordinary requirements.

Planting Tomatoes.—A few words on the above subject may not be out of place, especially as many people will soon have their plants ready for their fruiting quarters. The universal way of setting plants out is, in my mind, quite a mistake, people in most cases earthing the material up in the form of a ridge.

Thus when feeding commences the roots of the plant never get the full benefit. My idea is that instead of a ridge if a furrow was made, and kept so always, keeping the soil up at both sides, of course top-dressing all over alike; thus whatever you gave to them would go direct to the roots of the plant. A layer of cow-manure night with great advantage be laid in the furrow, washing it in as required.—J. G. PETTINGER, *Harrogate.*

5350.—Making a Tomato-house.—I should say the width of the house must be guided by the length of the lights and the number of them you have. You do not want any glass-lights for the front if you have this 18 inches high. Ventilators made of boards will do in the place of glass. You will require stout posts and cross-pieces of timber along the front and 9 inches away from the wall at back to support the lights, a strip of quartering nailed to the wall, and a 9-inch board fixed to it by hinges, and you have a top ventilator, which is easily worked by a pulley. A house 7 feet high is the least you can have to be serviceable.—J. C. C.

—Supposing that the frames are of the usual 6-feet length, and they are fixed at an angle of 45 degs. (a very suitable pitch for this purpose), with a 2-feet wall in front, that will give a height at the back of about 6 feet 3 inches, and a width from the back wall of 4 feet 3 inches. This will allow of two rows of plants being

grown along the front, and as the height at 1 foot from the back wall will be just over 5 feet, that would probably suffice—that is, if the path could be sunk 6 inches or a foot, so as to obtain more head-room. If you want more height, raise the front wall; if greater width, fix the frames (or rather lights) at a less pitch, in this case also the front wall requiring to be raised. But to make a really good job of it, I should recommend obtaining a sufficient number of other lights 2 feet or 3 feet wide to go along the top, hinging them to the ridge-plank fixed to the wall, and allowing them to fall on to the top of the long lights, these being carried in stout rafters. In this way the width of the structure could be easily increased by 18 inches or 2 feet, and made higher at the back also, with a 2-feet wall in front, while provision is made for ventilation also—a most important point. In any case you should have a 9-inch board hinged along the top, as well as ventilators in the front wall.—B. C. R.

5367.—Length of a Tomato-plant.—Plants of Perfection and Ham Green will often run 10 feet or 12 feet during the season, the seed being sown in early in the year, and the plants kept growing on freely. In a house only 6 feet high the plants should certainly be planted in pots or boxes placed right down on the floor, or even in the ground itself, and not on shelves or stages of any kind. But with such a limited space at command you would find it much more satisfactory and profitable to grow a dwarf or short-jointed variety, such as Field Gem or Conference, rather than those mentioned.—B. C. R.

5359.—Tomatoes in boxes.—Tomatoes are very often grown in orange and other cheap boxes which may be obtained from the grocers. Anything that will hold soil will do; its shape, provided it will hold half-a-bushel of soil, is not of much moment. If boxes have to be made or bought, in some cases it might be cheaper to run troughs the length of the house of sufficient size, say, a foot square, to hold plants from 15 inches to 18 inches apart. This will be cheaper than having separate boxes for each plant, and when not required the boards might be taken down and used to make stages or some other purpose.—E. H.

5365.—Yield of Tomatoes.—Plants of a good strain of Perfection (the selection or "strain" makes a lot of difference) will yield under skilful cultivation from 20 lb. to 25 lb. of fruit during the season, commencing in May and continuing until some time in October; Ham Green, 10 lb. to 15 lb., for though a fine handsome fruit, this kind is very long in growth and does not crop equal to the foregoing. Plants from seed sown the end of this

month should, if grown on freely, commence to ripen the first fruits at the end of May or early in June, and with a due supply of nourishment would continue fruiting until the end of October, at least, and until Christmas, or later, with the aid of a genial warmth.—B. C. R.

5364.—Tomatoes in a greenhouse.—With care it would be just possible to manage young Tomato seedlings and bedding plants in the same house, until the end of April, at any rate. Place the seed-boxes or pans in the warmest place, over the flue or hot-water pipes, until it is well up; then remove them to a shelf near the glass at the warmest end. Do not let the temperature fall below 50 degs. at any time, and as soon as possible draft the bedding stuff off into pits or frames.—B. C. R.

—If you sow Tomato-seed at the end of this month (January), and heat your greenhouse sufficiently to keep the plants steadily growing, the warmth will be too great for your bedding plants. You had better give up the raising of your own plants, and purchase what you want about the middle of April. There are sure to be plenty of Tomato-plants advertised for sale in GARDENING. At that time it will be safe to place in the open air all the strongest of your seedlings, if you protect them at night with a mat. Your house can then be kept warm enough for Tomatoes.—J. C. C.

5366.—Salt for an Asparagus bed.—One pound per yard should not be excessive, and in some cases half a pound per yard will be enough. Apply it now.—E. H.

5321.—Tomatoes under glass.—The best Tomato for market or any other purpose is undoubtedly Field Gem, and "Tomato Culture for Amateurs" is an excellent book on the subject for trade or private growers. Both are advertised in GARDENING.—B. C. R.

ROSES.

DAMASK ROSE (ROSA DAMASCENA).

In reply to several queries as to old Roses in general, and this one in particular, we may state that it is a native of Syria, from whence it was brought to Europe about 1270 by Thibault IV., Count of Brie, returning from a crusade in the Holy Land. In Syria this Rose is so common that there is a valley called the "Valley of Roses." It is a parent of the Hybrid Red Roses. The Damaska have pale-green leaves (three to seven leaflets), green shoots, with numerous spines, are of free growth, and hardy; the flowers are pretty in form (see illustration) and very fragrant. They need but little pruning. Among the kinds, besides the com-

Damask Rose.

mon one, are La Ville de Bruxelles, La'sa, Madame Hardy, Madame Stoltz, Madame Zouman, and York and Lancaster (true).

Marechal Niel Rose.—Reading from time to time in GARDENING of failures and difficulties in the growing of this splendid Rose, I ventured to send you a record of my experiences. I got a plant several years old about five years ago. It had been grown in a large pot and always proved a failure. I planted it in a well-drained narrow border, composed half of chopped turf and half of old hot-bed, inside a very small "cold house." Last year I cut 250 magnificent blooms from the plant; many when half expanded would not enter the rim of a bucket without a gentle squeeze, and every blossom when half blown down was surrounded

and hidden in glossy-green leaves. The moment I take the last blossom I cut every flowering-rod quite away, leaving only what I may call the stumps or main stems of the Rose. These soon put out new wood in long trailing branches which I tie in 9 inches apart, and the same distance from the glass. By the winter these branches begin to drop their leaves. They are not much shortened, and in spring they flower at every joint. As soon as the flower-buds are plainly discernible I soak the border with weak manure-water. If three blossoms come at one joint I pick off the two side ones. I never have syringed, and have never seen a green-fly on the Rose. I always cut the blooms early in the morning at a point a little past half open; they then keep well in water and open fully in a vase.—J. I.

5369.—**Tea Rose cuttings.**—The rooted cuttings should be removed and be potted off singly in flower-pots 3 inches or 4 inches in diameter. Plant them carefully and keep them in frames or a greenhouse until well established. Good soil for them would be yellow loam, about four parts, one part decayed manure, and one part leaf-mould, with a little sand added; or if leaf-mould cannot be obtained, fibrous peat is excellent for Tea Roses to use in the same proportion.—J. D. K.

— You would perhaps be wiser to pot off the cuttings as soon as it can be determined they have rooted. Use a sandy compost and small pots, giving more substantial soil later on when shifting into larger sizes, or they might be planted out in June next.—P. U.

5361. **White Cluster Rose.**—There are two White Roses which pretty near answer the description you give; these are *Aimée Vibert* and *Mme. Plantier*. The last-named is, I think, the one you have seen, as you say it is almond-scented, and *Mme. Plantier* has certainly a very delightful fragrance, and, as you say, it makes a good standard as well as a climber. It is the only good White Rose that I am acquainted with that is hardy enough to grow on a wall with a north aspect, where it grows and flowers as well as I could wish.—J. C. C.

— Probably *Aimée Vibert* is meant. It makes a good drooping standard. It is a very old Noisette.—E. H.

Single Roses.—In a recent article on Single Roses in *GARDENING ILLUSTRATED* the *Simplex* is not named. It is a very pure White Rose, with a large bunch of orange stamens, the foliage bright-green. In a warmer country I believe it is evergreen. Here it sheds its leaves in the winter.—M. C. B. H.

FRUIT.

THE WALNUT (*JUGLANS REGIA*).

This is comparatively but little planted, a singular fact when the beauty and value of its wood are taken into account. For gun-stocks and much of our finer sorts of furniture Walnut timber is invaluable. Walnuts, moreover, are free-growing trees on almost any kinds of soil, and the crops of nuts which they produce would pay at least the rent of the land on which they

Fig. 2.—Walnut "Late or Jean."

grow, whilst its freehold might be purchased with trees four years of age. Walnuts in a landscape are also trees of mark, their magnificent heads of fine foliage in parks or paddocks rendering them especially adapted for such situations. They associate well with Oak, Beech, Elm, Spanish and Horse-Chestnut, as well as with various other trees, and they do not mix the land more than their companions do. Their smooth glossy leaves are washed clean with every shower, and the foliage is not so thick as to throw the rain off the Grass on the air currents from the ground. They bear the

branches. There are therefore no trees in park or pasture under which herbage grows better than it does under Walnuts. Besides, Walnuts come into growth late, make their growth quickly, and lose their foliage nearly all at once after the first autumn frost. Thus a chance is given to take the leaves out of the way, so as not to injure the Grass, while the shining dark young wood, with the greyish mature limbs, are left full in view. As to any tree that will grow more quickly into a size to be useful I do not know where to look for it. I

Fig. 1.—Walnut "Large-fruited."

have seen old Walnut-trees that measured from 60 feet to 90 feet in height, diameter of branches from 60 feet to 96 feet, and of bole or trunk from 3 feet to 5 feet diameter, and no doubt larger trees are elsewhere to be found. Considering, therefore, all its good qualities, what can be the reason that the Walnut is not more extensively cultivated in this country? Is it because young folks will sometimes pillage a few Nuts rather than spend their cash in the purchase of French Walnuts? Surely not. That the French grow Walnuts more extensively than we do is certain. They find, too, a ready market amongst us for their Nuts, which had we more trees we might share with them. The cuts here given illustrate the three most popular forms of the Walnut to be found in our markets in their season. Their names are *Large-fruited* (Fig. 1), *Late or Jean* (Fig. 2), and *Heart-shaped* (Fig. 3).

5292.—**Grafting fruit-trees.**—There are several styles of grafting suitable for fruit-trees. Which of these it would be best for you to adopt depends upon the stocks. For example, if you have a few fruit-stocks about three-fourths of an inch in diameter, or wish to work some desirable variety upon a kind in less favour with you, and the wood of which is about the same substance, then I would choose what is known as *sids* or *whip-grafting*. Supposing you wish to work upon a stock which has been formerly by cutting down an old tree, or one, say, over 2½ inches through, then one of the styles of *wedge-grafting* would be best. There are many cases where a healthy tree of an inferior variety can quickly be turned to account by grafting; and I have pleasure in giving a brief outline of the two methods most generally used. *Sids* or *whip-grafting* consists in cutting the stock to as short a point as circumstances will allow, and then paring away about 3 inches of the remainder. You should pare this away in a slanting direction, the smallest portion of the cut being at the lower part. As to the depth of the cut, this must depend entirely upon the size of graft, and it will perhaps make the operation more simple if we prepare the latter at once. The graft or scion should be a healthy piece of wood which grew the previous year. Cut it into lengths of some 6 inches to 8 inches: then take it firmly between the finger and thumb of the left hand, and cut away in a slanting direction from top to bottom. This cut should go right through the graft, and be as nearly as possible of the same length as the portion pared away from the stock. The edges of the graft and those of the stock should be brought into contact; and from this we must decide how deep to pare away from the latter. Avoid cutting either in such a way that the graft

formed, and pare away more or less from either stock or graft until the two fit together. This is most essential, especially at the lower portions. The operation of *tonguing* is not necessary, but it often assists in forming a stronger union, and also keeps the graft in position until firmly tied. This consists of making a downward cut in the stock, and a corresponding one in the scion, the latter taking an upward direction. When the cut of the former receives the "tongue" of the graft, they fit together firmly, and may be tied over with matting. *Wedge-grafting* almost explains itself. I make two cuts in the thick bark of the stock, and trim the lower part of the graft into such a form as will fit or wedge into the cut. It often happens that the graft is too large round to allow of a simple wedge meeting edge to edge of the two barks. In this case the upper part of the graft is cut away somewhat, and forms a seat, which rests upon the top of the severed stock or branch. This is much easier to illustrate than to describe; but if the main principle of keeping the edges of both stock and scion as nearly as possible together be duly attended to, it matters little in what way this is secured. When tied together firmly we must contrive some means of keeping the drying influence of air from the parts operated upon. Some use a composition of pitch, resin, and tallow; others a little well-worked clay, or any stiff soil of a similar character. If the latter be placed around the graft and stock, and then tied with a second piece of matting, it will answer the desired purpose. Or any stiff soil, with a little Moss around it to keep the whole together, will do equally well. Grafting should be done when the sap is commencing to rise. March is a good month. It often happens that prunings or grafts from a desired kind are severed some month or so before this; but it will not much matter if you stick them in damp soil upon a north border. Endeavour to have the graft a little less forward than the stock; this is easily secured by adopting the above plan.—P. U.

5363.—**Rooting cuttings of fruit-trees.**—I do not think you are likely to strike cuttings except those of Apples, and in most cases these want to be rather large pieces. All *Codlin Apples* may be increased in this way by taking branches about 2 feet long, and burying 9 inches of the stem in a partially shady place. I have succeeded in striking a few other Apples, notably *Brumley's Seedling*, but they require the protection of a cold frame to shelter them from drying wind and bright sun during the months of April and May, as I found up to that time the cuttings remained without shrivelling; but if left exposed the majority gradually died away. Protected in the way I have suggested, the cuttings retain sufficient vitality to form roots during the summer. Treated in this way the other subjects you mention may possibly grow. You are, however, rather late this season. It would have been better to have put in the cuttings at the end of October. Whenever

Fig. 3.—Walnut "Heart-shaped."

you do the work you must be careful not to allow the soil about the cuttings to get dry for the first year, or they will certainly die.—J. C. C.

5384.—**Pruning Vines.**—It would be rather unwise to cut away all the old spurs and trust to the shoots breaking away from latent eyes in the main stem for a crop. Better trust to the old spurs this year, and start away young roots from the bottom of each Vine, training them over the main stem. Encourage these shoots to get strong, and when the leaves fall prune back to firm ripe wood in the young rod over the main stem, and cut away every-

thing on the main stem as far up as the young rods reach. In a couple of years you will have young rods that will take the place of the old ones, and the latter may then be cut away altogether.—E. H.

5379.—**Heating a vinery, &c.**—A good boiler, well set, and a proper quantity of piping is a decidedly better, and in the end more economical, way of heating a house, or houses, of any magnitude than flues, not to mention the greater safety. But the most economical system of all is a combination of pipes and flues, which if carefully planned and executed, gives the best results from a given amount of fuel. It would certainly be better and cheaper to heat a range of three houses from one boiler and furnace than three, and the labour of stoking would also be much less.—B. C. R.

— When there is more than one house it is certainly more economical to have a hot-water apparatus, as then one fire will suffice. In the case of lines a fire is required for each house. In any case first cost of a hot-water apparatus is greater than that of a flue, but the latter requires more fuel, although it will do with less attention. For myself, for a single house I prefer a good flue, especially when the gardener does not reside on or near the premises.—J. C.

5312.—**Lean-to house for a Grape-Vine.**—You could grow all the three things mentioned in such a house. The *Lapageria* would succeed well, and the best way is to plant it out in the house. Take out a good square of the ordinary soil and make up a peat and turfy loam-heap, thoroughly good soil to form a fine foundation, so to speak, and putting in plenty of crocks in the bottom for drainage. Use also with the soil nodules of charcoal and sufficient sharp silver sand to make it pretty light, as one does not require the compost very heavy. Oleanders you could get also, but they require more warmth to really succeed with them, especially to expand the flowers in fullest beauty. The reason why *Neriums*, as the Oleanders are botanically, do not usually look well, is that they do not get sufficient warmth, and are seldom pruned or repotted. The time to repot is the spring, and when well established in the pots, assist them with occasional supplies of weak liquid-manure. When they have finished flowering, let the soil get rather dry, and cut back the young shoots to about two buds from the old wood, not more. Kithous peat and good turfy loam forms a good soil for them. When good kinds are grown well they are very beautiful.—C. T.

— The *Lapageria* and the Tea Roses will do in the cold-house; but the Oleanders should be kept from severe frost, though a degree or two will not harm them.—E. H.

5317.—**An old Pear-tree.**—I presume the tree to be a standard. If so, it probably wants some of the weak branches cut out of the middle of the tree to let in more light and air. The roots, however, should not be touched. If you find the growth is weak you had better give the roots a top-dressing by laying on the surface half a cartload of rotten manure, spread out as far as the branches extend. It is very unusual for this Pear to bear so freely, so that it is not likely that you will get such a heavy crop for some time. If you do, you had better make an effort to thin them out early in August. A man with a ladder could go over a large tree in an hour or two, and no Pear will better pay for a little extra labour than the Chaumontel when the soil and climate suit it.—J. C. C.

— If the trees bear freely the roots do not require pruning. To increase the size of the fruit top-dress now with manure.—E. H.

5294.—**Cow-manure.**—Cow-manure in a thoroughly decayed state would not hurt the *Rhododendrons*, but if used fresh it would, and it is only when the plants are in poor condition that it is at all necessary. Mr. Anthony Waterer, whose beautiful nursery at Knapp-hill is in a large measure devoted to *Rhododendrons* and American plants, mentions that they may all be said to delight in and to require what is called peat-soil. It was at one time believed that they would not thrive in any other. Experience, however, proves the contrary, and it is now found that *Rhododendrons* and *Azaleas*, which are the most important of this class, as well as any other of the more vigorous-habited plants, succeed in almost any

soil that does not contain lime or chalk. In many sandy loams they grow with as much vigour and luxuriance as they do in peat; in fact, in almost any loamy soil free from lime or chalk may be rendered suitable for them by a liberal admixture of leaf-mould or any fibrous material, such as the parings of pasture land. When the soil is poor thoroughly decayed cow-manure forms one of the best manures for these plants. It is important to remove the seed-pods immediately the flowers have fallen.—C. T.

— *Rhododendrons* do not require fresh or rank manure of any kind. A little old mellow cow-manure will be beneficial to *Rhododendrons*, especially if the plants are strong and old. Leaf-mould would form a better mulch for young plants than cow-manure. Unless much overdone it is not likely they will be killed or injured.—F. H.

CHRYSANTHEMUMS.

NUMBER OF PLANTS TO GROW.

Young growers are often much puzzled to know how many plants they should cultivate with the intention of having a given number of exhibition blooms at a certain date. Many persons think it right to grow a very large number of varieties, although this is all right so far it is very often carried to excess. It is much better to select a fixed number of varieties suitable for the purpose intended, growing a number of plants of each, than to be burdened with a host of kinds that cannot be relied upon for the object in view. Several varieties are admittedly useful for other purposes than supplying exhibition blooms of the highest quality; but if the production of these is the main point, varieties that do not afford them should be eschewed. I strongly advise all who have not had experience to bear in mind when forming collections that variety may have claims, but not in all cases value. If an exhibitor wishes to stage forty-eight distinct blooms, twenty-four of which may be *Incurved* and the remainder *Japanese*, he should grow at least thirty-six varieties in each section, as all are not to be depended upon to produce what is required. In some seasons one sort is quite useless, whereas the next year quite the reverse may occur. Casualties, too, may happen during the season of growth quite unexpectedly, such as shoots being broken by wind just at a critical period, and other unforeseen circumstances; therefore not less than the number stated should be depended upon to insure success. These should consist of the very best kinds, as nowadays—that there is such a large number to choose from in each section—it is waste of time and space to grow inferior sorts. An exhibitor cannot expect to be successful in such a large class with less than 300 plants, or 150 in each section. In the twenty-four class, supposing them to be half *Incurved*, and the remainder *Japanese*, twenty-four varieties in each section are not too many to grow, and the total number of plants should not be less than 150. When confined to a smaller class of, say twelve distinct, either *Japanese* or *Incurved*, the selection should be more rigid than in the larger classes, as there is not so much margin allowed for an inferior specimen or two in smaller, where all are expected to be of the first merit. Twenty-four names should be chosen, and about seventy plants grown, giving the preference to the very best kinds, of course, selecting those that are known to be the most certain producers of fine flowers. In competing in a class for twelve blooms, either *Japanese* or *Incurved*, the general good quality should run right through the stand, as in such small classes there is not the same opportunity to insert a moderate bloom or two as there is in larger classes. For the benefit of inexperienced growers I append a list of the best twenty-four kinds in each section, and the number of each variety it would be advisable to grow to compete successfully in good company in the open class for twelve blooms either *Japanese* or *Incurved*:—

TWENTY-FOUR JAPANESE VARIETIES.—Three Mlle. Therese Rey (creamy-white), four Vivand Morel (deep mauve), four Charles Davis (bronze-yellow), four Edwin Melyneux (orimuse), two gold reverse), four Sunflower (rich yellow), two Avalanche (white), four Florence Davis (white, greenish centre), three Col. W. B. Smith (old gold, terra-cotta shaded), three Etois de Lyon (deep lilac-rose), three G. C. Schwabe (bright carmine-rose), three William Seward (blackish-purple), four Mlle. Marie Hoate (white, slightly

shaded with blush), four W. Tucker (helicate-rose), four Stanstead White (white), three W. H. Lincoln (rich yellow), three Excelsior (bright rose-cerise), two Mrs. C. H. Payne (rosy-blush), three Mrs. Falconer Jameson (chestnut-bronze, tinted and striped yellow), three Mrs. P. A. Spanning (yellow), four Lord Brooke (golden-orange), two Wahan (light rose-pink, edged purple), two President Borel (violet-rose), Mme. Edouard Rey (soft lilac), two Mme. Octavie Mirabeau (white and rose, edged amaranth).

TWENTY-FOUR VARIETIES INCURVED.—Four Lord Leicester (primrose), four Empress of India (pure white), four Queen of England (rosy-blush), four Gohlen Empress (golden-yellow), three Gohlen Queen of England (straw yellow, with bronze suffusion), four Alfred Salter (clear lilac-pink), three Princess of Wales (white suffused rose), two Lord Wexley (bronze red), four Violet Temlin (purple), three Prince Alfred (rose-carmine, shaded purple), three Jeanne d'Arc (blush-white, tipped purple), four Hero of Stoke Newington (rose-pink), three Mrs. S. Coleman (bright-rose, shaded yellow in the centre), two Mrs. Keales (creamy-white), three Princess Tock (blush-white), two Robert Pittfield (silvery-mauve), two Miss M. A. Haggas (bright yellow), two Lady Dorothy (pale cinnamon-buff, suffused rose), three Mrs. W. Shipman (fawn), two Mrs. Danier (mauve-yellow, shaded red), two fancy Kendall (coral-red, sport from Violet Temlin), two M. P. Bahant (carmine-rose), three Mrs. Norman Davies (golden-yellow), two Nil Desperandum (orange-red). E. MOLYNEUX.

WHAT TO DO WITH OLD CHRYSANTHEMUM PLANTS.

THIS is a question which is often asked now by a large number of amateurs. With a large number of growers the practice is to take the number of cuttings required for the next season, then to throw the old plants away. Now, I would strongly advise all those who desire cut flowers for house decoration, &c., to adopt the following plan: As soon as past their best cut them down, keeping the roots just moist. A cold frame or cool greenhouse is the best place to keep them until the spring. A plot of open ground should now be manured and dug up roughly, remaining so until April; it should then be levelled down and trodden firm. The plants may now be turned out of their pots, the old drainage removed without damaging the roots, and planted firmly in rows 3 feet from plant to plant, and 4 feet from row to row. As soon as it is noticed that the plants have made a start all the young shoots except six must be removed; as soon as these are 6 inches in height the tips must be pinched out. This will be the means of forming other shoots. Again, one more stopping the second week in July is all that is needed to form well-shaped plants. Each plant ought to have one stake in the centre as a protection against wind and rain. During dry weather a soaking of water should be given; beyond this very little attention otherwise is needed. During October, according to the weather, the plants can be taken up with as good a ball of soil as possible. Should the ground be very dry a good soaking of water should be given overnight. The best grown plants can be potted up, the remainder can be placed close together on stages in a greenhouse, according to room. This plan, though not a new one, commends itself to a large number of amateurs who are away from home during the day. From experience I have found it a first-class means of having abundance of good flowers. Again, if the buds are removed, only leaving one to each shoot, the blooms will come extremely good. It seems somewhat strange to me that gardeners do not grow a number of plants every year on this plan for cut bloom. We have had here upwards of a hundred plants lifted from the garden, placed in a cool greenhouse, furnishing cut blooms by the hundred, many of them were from four to six inches across. As regards the sorts, that is a matter I would leave to my readers. I may say one and all are very good for the purpose. It is not my desire to discourage by any means the cultivators of large blooms. By all means grow on a few plants for this purpose. But after all it is somewhat disappointing not being able or desirous to cut out large blooms for house and other purposes.

FREDERICK BUSH.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton Street, Covent Garden, London. Letters on any subject should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot be obtained, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, suits, and instances occur so frequently that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5100.—Cytisus cuttings.—When and how is the proper time and way of making and striking these?—H. T. M.

5107.—Late Potato.—Will anyone kindly tell the name of a good medium-sized late Potato for a loamy soil, with gravel beneath?—W. Y. Z.

5108.—Hyacinths in glasses.—I have some Hyacinths in glasses. Would any of your readers inform me what to do with the bulbs after flowering? I have no garden.—AMATEUR.

5111.—Lamp for a propagator.—Would "J. C. C." kindly say whether the lamp for a propagator has a single or duplex burner, and, if single, what width of wick is necessary?—H. T. M.

5110.—Eaten Pinke.—My Pinke are being eaten off by something; is it the birds or slugs? What preventive I adopt to save them? Will they recover growth this season?—SUSSEXIAN.

5111.—Growing Lilium auratum.—Would anyone please to inform me the best way of growing the Lilium auratum? I intend putting one in a bedroom-window with a west aspect.—AMATEUR.

5112.—Hope on a wall.—I want to cover a high wall with Hope, should they be cut back every year before the new growth starts, or should the old twigs be left for the new growth to cling to?—NOTICE.

5113.—Birds eating Crows.—What can I do to prevent birds eating my Yellow Crows? I have tried three or four round sticks, but it spoils the look of the border, and is not very successful.—NOTICE.

5114.—Currants and Raspberries against an iron fence.—Will any of your readers kindly tell me if Currant-bushes or Raspberry-canoe will do well if planted against a galvanised iron fence facing S.E.?—WYK.

5115.—Gladolus seed.—I have sown a quantity of seed of Gladolus gandavensis. I shall be glad if someone would kindly inform me how I can best raise plants from this seed, and how soon they would flower?—ABANDON.

5116.—Maiden Fern and Selaginella.—I want to get up the stock of Maiden-hair Ferns and Selaginella. Should they be grown from seed or young plants bought? I have only a good greenhouse.—NOTICE.

5117.—Pruning Roses.—Will someone kindly tell me how and best to prune the following Roses: Duke of Wellington, Prince Arthur, Abel Carrere, Mrs. Isaac, and Charles Lobbier?—ANNALS, Buffon-on-Val.

5118.—Yellow Carnation.—Will anyone kindly tell me the name of the new Yellow Carnation which is said to be as much larger than Geranium or Fricke of Paudral, and if it is a suitable one for growing out-of-doors?—E. S.

5119.—Winter-flowering "Geraniums".—I shall be obliged for some information about winter-flowering Zonal "Geraniums"—Whether it will be best to cut them down when done flowering? The plants are rather large.—C. P. L.

5120.—Everlasting Peas.—I wish to cover a large railing next summer with a hedge of Everlasting Peas. Will someone kindly inform me when is the right time for sowing in the open, or should they best be raised in a greenhouse?—NORFOLK-RAISER.

5121.—Renting a market garden.—Will anyone kindly tell me if a market garden rented on a yearly tenancy from May 15th can be taken possession of by a fresh tenant before the following 1st of May? I think not. Please tell me if I am wrong?—M. M.

5122.—Brown spots on a Ficus.—What is the cause of brown spots appearing on the lower leaves of the Ficus elastica and of their turning a yellow colour? Is there anything to prevent the leaves changing colour, and, I suppose, of their ultimately dropping off?—I. K.

5123.—Management of a vineyard.—I want to start a vineyard, and will be the first and general management of it in our climate in June? It is a loan-in house located by a lake. Also, how can I get rid of wood-louse, as the house is badly infested with them?—SUSSEXIAN.

5124.—Aster Thomsoni.—I don't see this lovely Michaelmas Aster (as illustrated in GARDENING, No. 755, of September 19th, 1893) in any seed-catalogue that I have. Will someone kindly say where seeds of this Aster are to be procured? Also best time and method of sowing, &c.?—K. A. M.

5125.—Sowing Peas.—I shall be greatly obliged if someone will inform me if Peas sown at the present time in pots require a higher temperature than that of a cellar or unheated spare room without fire? Also, how long they should remain in the pots, before transplanting?—FRANCAIS.

5126.—Cuttings of indoor plants.—Will someone kindly tell me the best time to take cuttings of the following stove plants: Begonia Williams and Prince of Orange, Epiphoria Jacquiniiflora, Poinsettia pulcherrima, Linum flavum, Allamanda Chelsoni, and Gardenia Fortunei?—IMPROVING.

5127.—Peach dropping its buds.—I have just begun to grow Peaches. One tree is Royal George, the other Early Rivers. This latter drops its buds instead of opening them; the Royal George doesn't do so. What can be the reason? This hasn't been observed in previous years.—NUS. BARTON.

5128.—An ash-pit.—I have a large diseased ash-pit near a south-west wall, on a fairly stony spot, about 6 feet or 7 feet deep inside. Will anyone kindly tell me to what use I can put this—in particular, whether it would be suitable for a Mushroom-bed, and, if it is, when and how to prepare this?—O. M. C.

5129.—Climbers for a greenhouse.—My greenhouse is 15 feet long, 12 feet high at back by 4 feet in front. I have painted a Gloire de Dijon Rose in the night, at the back wall. What would be the two best climbers to plant on both sides of the Rose, so as to cover the wall and make a show?—A. M. M.

5130.—Setting a coil boiler.—Would someone kindly oblige me with a few hints as to how to set a coil boiler? Also, how should I fix the socket (not expansion joint) pipes to the coil? Size of pipes 3 inches, and coil 7 feet with three water valves. Would it heat a house 15 feet by 8 feet, pipes all round? Any useful hints would greatly assist.—AMATEUR.

5131.—Unhealthy Puchsias.—Would someone kindly inform me what is the matter with my Puchsias as they turn white under the leaves and these then drop off? They make good growth at first, and are seemingly healthy. What can I do to remedy it? I pot them in loam and leaf-mould, and keep them in a temperature of 50 degs.—A. NEW BRUNSWICK.

5132.—Oil-stoves.—I have seen in GARDENING 111 different lines that oil-stoves are used by some people for heating greenhouses, and I have also seen that they use a pan containing water on the stove. May I ask, if the steam from this water is a bad thing for plants? Won't it make the leaves shrivel? A few hints on this subject would greatly oblige.—B. E.

5133.—Old Christmas Roses.—I have many old plants of the Christmas Rose, and I find the roots are infested with large yellow grubs about an inch long or more, and coated with a kind of cobweb. Will anyone enlighten me as to the name of this pest, and how to get rid of it? They sap the nourishment from the roots and spoil their blooming.—CHAS. E. LONO.

5134.—Climbers for a window-case, &c.—I wish to know the names of the nicest and most lasting climber and climber to plant in a window-case, having a fountain in the centre with a pan filled with water? And what aquatic plants would be suitable for the basin in which are some gold-fish? I should be obliged for any hints as to their management.—J. K.

5135.—Iron fencing.—I have about 200 feet of iron fencing running on one side of my garden, facing south. The iron bars being about 1 1/2 inches apart. I thought of putting a lot of fruit-trees up here—Pears, Apples, Plums, Peach, &c. Would it be successful? It is certainly the best position in the garden, and it seems such a pity to lose this favoured spot.—T. R. CLEVELANDIAN.

5136.—Tomatoes for market.—I have grown Tomatoes for several years past, and generally find Latham's Excelsior a good sort; but this year, having a few hours nearly lost to Tomatoes, I should like to grow Hawkwood Park and Large Red. Would someone who has had experience in the cultivation of the above say which is the most profitable to grow?—G. M. C.

5137.—Pompon Chrysanthemums.—Will anyone kindly give me a list of fine Pompon Chrysanthemums? Not Miss. Deorange and others of that class which are entered in lists as Poppoms, but the lovely little button flowers of various colours which flower so profusely in October, and last for weeks when out. I saw a charming list of these this year in the autumn, but could not obtain the names.—HARROW.

5138.—Removing Currant-bushes.—A friend of mine took up several Currant-bushes for the purpose of removal, and dug them up with the roots exposed all through the large soil. He has offered me several of them, but before filling any space in the garden with them I should like to know if they are likely to be of any use, as the roots was extra severe in this part—viz., Essex?—H. N. II.

5139.—Removing hot-water pipes, &c.—I am about to move my boiler and pipes from one house to another. Will the India-rubber rings again; they have been in use a year? My house is a lean-to against a south wall, the door is at the west-end. I should like the stove at the east-end; but have heard that the draught is better if the stove face be the south. Is this the case, or is it of no real consequence?—G. M. C.

5140.—An unsatisfactory Heliotropis.—Will someone kindly tell me why a Heliotropis growing up the side of a wall, with a copious side of glass, and the root glass, does not succeed? It grew very well until some weeks ago the leaves began to wither and then turn black, and I see the young leaves that are sprouting out are quite black. The wall is next the kitchen, and when it is frosty I keep an oil-stove burning.—M. P. H.

5141.—Climbers for a wall, &c.—Will someone kindly tell me what creeping plants I should plant on a house facing to the north? It is a two-story house, but very high, and I want to cover it up. Would Virginia Creeper grow in a northern aspect, or Ficus virens, or what would flower best? What shall I best plant to cover a wooden paling, about 5 or 6 feet high, in the same aspect? This is shelter. Would Cistaceae do well?—H. S.

5142.—A propagator.—In GARDENING, January 20th, page 664, in answer to query 5276, instructions are given for making a propagator. Now, I would like to know, are the seeds sown in the Cocoa-nut-fibre or sawdust, or in a box bed with prepared soil? Also, if I read the instructions rightly, there appears to be only an inch between the two sides of the glass and the zinc tray. Is this sufficient?—A. M. C.

5143.—Currant mite.—Last year I saw an article in GARDENING about the Currant-bush mite. I cut mine down, but I see the young wood is coming just the same again. I have used an insecticide to the bottom of the trees, but the buds seem as large as ever again. I may say my ground has a stony bottom and light soil—what soil there is. But I have used pretty well of cow-manure since I came here two years ago. What shall I do?—OUR SUBSCRIBER.

5144.—Making a propagator.—I propose to make a propagator on the lines laid down by "J. C. C.," but different in size—viz., 1 foot 8 inches by 1 foot 6 inches. Would not the perforated zinc require support, as I want it for pot forcing, and is not a tank better than an open tray for the water? What size lamp should I get, and ought the box to rest squarely on the ground, or should a space be left for air? What depth should the box be?—AN AMATEUR.

5145.—Plants for a narrow border.—I should be very glad of suggestions as to what I can plant in a border 1 foot wide. The border is over 100 feet long in front of a brick wall, which is covered with Ivy. Bedding-out plants are troublesome and expensive. I want something that I can plant to remain permanently, and, if possible, look well most of the year. Ferns would project too much, as there is constant traffic on the walk.—CAROLINA A. OATES.

5146.—A flower-garden.—My flower garden is made up of two plots, with five beds in each. The middle beds are round shape. I intend planting two beds of the outside ones with Scarlet "Geraniums," the other two with Two-week Stocks, of one plot. Two of the next plots with Painted Lady "Geraniums," and two with Yellow Calceolarias. What would be the best annuals to put in the middle beds so as to make a show from July? I would like the centre beds to be a little higher than the others.—A. M. M.

5147.—Growing Tomatoes.—I propose to grow them on the following plan: To make a box 12 feet long, 12 inches wide, and 12 inches deep on front stage of a greenhouse, or would it be better to grow them in 10-inch beds? If in the beds, should I have to bore holes in the bottom, and, if so, what distance apart? Also please name a few of the best sorts for setting their fruit and for profit? Also when to sow seed, as I have no artificial heat? I intend growing them on the single-stem system.—AMATEUR.

5148.—Pyrethrums, single and double.—Wishing to make a small and choice collection of these, I have consulted a number of catalogues, where I find a good many, although differing in name, are described as of the same colour. I am therefore at a loss to know which one to choose in any particular shade. I want only those possessing the largest and best formed flowers in their respective shape or colour. Will someone who has had the advantage of examining good collections of the older and newer varieties help me to make a selection?—HOBBS.

5149.—Growing Peas.—My garden will not grow Peas well. Not more than half of the seed sown comes up, although it is well protected from frost. Some of the seeds are apparently eaten by a small thread-like worm. The soil is moderately light and good. I sowed a great deal of night soil has been put on it in the past. Will someone kindly tell me if lime would be of any use? If so, whether it would be too late to put it on now, and also the quantity which should be put on each rod of ground? I should also be glad to know if manure should be put on as well as lime? The ground has not been manured this winter.—J. P.

5150.—Heating a greenhouse.—I last autumn had a greenhouse put up 21 feet by 10 feet. I had two rows of hot-water pipes, 1 inch flow, and return along one side and one end. I had a boiler, but no water apparatus, but the fireplace is so small that one can get much fuel in, not enough to last all night. I find also that even in the daytime, when I am about my work, I can barely keep it up to 10 degs., and at night with an oil-stove burning the temperature of the house goes down nearly to freezing point. Could you tell me what to do? Ought I to have a larger boiler and more pipes round the house, or would a larger boiler be enough?—E. B.

5151.—Persian Lilacs.—According to advice in GARDENING I potted up in October a sturdy little Persian Lilac (white), which has flowered three seasons in the garden. The pot was covered with leaves and placed in a sheltered position out-of-doors until Christmas, when it was removed to a warm-house, well syringed daily, and had every care. The plant is growing nicely, but instead of the wealth of bloom which I had hoped for it has developed nothing but leaves, with the exception of one or two flower-sprays at the ends of the new wood. The bushes grown on in the garden are now covered with numbers of plump flower-buds. Will anyone tell me the cause of this? I thought that the flower-buds were formed in the summer, before the fall of the leaves; if so, what has become of them?—HOBBS.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5152.—Compressed Sphagnum blocks (W. H. Binks).—No, I cannot inform you, as I know nothing of them.—M. H.

5154.—Cattleya citrina (E. E.).—This plant may be grown with Odontoglossum, and it should be watered a trifle warmer, and be kept dry at this season.—M. B.

5155.—Crotid book (H. H.).—The book you refer to is not mine, and it is doubtful if ever you will see mine now, as it has been sold to incorporate with another work.—M. B.

5156.—Adiantum Capillus-venere (G. H. Ward).—You cannot do better than to pot it in a mixture of peat and sand, and half manure in a pot made of sandy, having some broken brick rubbish mixed with it.—J. J.

5457.—*Lisianthus princeps* (T. M.).—The plant you name is a native of New Grenada, where it grows at great elevations. It is said to be one of the noblest plants in existence. I do not think the plant exists in Europe at the present time.—J. J.

5458.—**Other Orchids with Odontoglossums** (J. J. Pillej).—I think nearly all the kinds you name would grow with these plants, but one I am sure will not, and that is *Odontoglossum*; its method of treatment see on page 63 of this issue of GARDENING.—M. B.

5459.—**Palms spotted** (B. S.).—I should imagine from the small specimen sent that your plants had been subjected to too low a temperature, with an excess of moisture in the atmosphere. Keep the plants in a higher temperature, and do not let them become dry at the roots.—J. J.

5460.—**Sanchezia** (*S. Morris*).—I cannot make out how anyone having a house for plants can allow them to get into such a state, for the present specimen is so thoroughly smothered with thrips and with thrip-marks as to utterly prevent me from deciphering the thing—in fact, almost the genus; but this I give, but I cannot give the specific name.—J. J.

5461.—**Vanda Roxburghii** (J. F. F.).—The plant you sent a sample appears to be of this species, but a little remained for identification that I cannot be quite sure the sample is of no value, and I have put on the file. This *Vanda* should be started on blocks of wood hung up in the East Indian-house. When it begins to root give it plenty of water.—M. B.

5462.—**Thrips on Orchids** (*Humphrey Clunker*).—"Mothew thrimble" presents his compliments, and begs to say the best way of preventing thrips from damaging Orchids or any other plants is to destroy them. To do this there are many insecticides recommended, but it is impossible for me to say which is the best. Send to your local nurseryman, he will direct you.—M. B.

5463.—**Orchids for a bay-window** (A. S.).—You are giving proof to my assertion of the increase in Orchid culture, though but in a small way. You need to be very careful in the management of the plants in the places you propose. The following will perhaps be successful: *Cymbidium Lowianum*, *Cypripedium insigne*, *Lycasta Skinneri*, *Lycasta aromatica*, *Odontoglossum Alabastrum*, and *Oncidium macranthum*.—M. B.

5464.—**Apelandra Roezlii**.—T. W. sends me a fine spike of this beautiful plant which I take to be one of the very handsomest members of the family for winter decoration. It has large opposite oblong green leaves which are more or less shaded with silver between the veins; the spike is terminal and dense; the flowers are a rich orange-scarlet. This plant seeds freely, and the seedlings which would be made use of for decoration in various ways, the earliest being the most beautiful. I have seen those later will prove equally useful as annual plants.—J. J.

5465.—**Epeoria**.—J. Harding requires me to name half-a-dozen good kinds for flowering, at the same time mentioning that he is a great admirer of the minata section. This may be, but "J. H." must recollect that the minata section are plants that do not require much pruning, and therefore are not suitable for him. The following half dozen kinds are very beautiful, and require to be cut hard back each year: *Campanulata*, which produces long spikes of bell-shaped flowers which are bright red; *Campanulata* like the last, but having pure-white flowers; *Hyacinthiflora fulgens* is a very fine flower of a bright-pink. *Mont Blanc*: This is a compact growing plant, bearing dense spikes of pure-white flowers. *Sunset*, fine variety, deep-red flowers, tipped with rose, and *Tricolor*, deep-red, shaded to a rose.—J. J.

NAMES OF PLANTS AND FRUITS.
. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, W.C.
Names of plants.—*F. Verel*.—*Leslia furfuracea*, *Dendroium biglandium*.—*G. Marr*.—A very good variety of *Cypripedium villosium*.—*C. M.*—*Blechnum Spicatum*; *Cyrtolium carolinianum*; *Polystichum angulare Wollastonii*.—*M. B.*—The flowers you appear to be a very bad form of the typical *Odontoglossum varicosum*.—*A. H.*—Your *Odontoglossum* Bessel is about the poorest form of the species we have ever seen. There is nothing of the majus link at all. The Fern is *Polystichum angulare Wollastonii*.—*W.*—Largest piece, *Acacia Drummondii*; small piece, *Acacia lineata*. Please number specimens in future.—*Begonia*.—Flowering plant, *Sparmannia africana*; smooth leaf, *Lonicera graebniana*; *Begonia*, *B. fuchsoides*. Number specimens in future.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of Fruit.—*M. L. B.*—Apples; 1, Pearn's Pippin, 2, Wellington, or Dumelow's Seedling.

TO CORRESPONDENTS.
We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.
Pine.—Apply to Mr. Geo. Moore, salesman, Covent-garden-market, London, W.C.—*E. E. Fowler*, Fern-merchant, York-hire.—Apply to Mr. W. Thompson, seedman, Tara-street, Ipswich, Suffolk.—*A. B. C.*—Apply to a dealer in artificial manures. No doubt, if not in stock, he will procure it for you.—*W. B.*—Apply to Messrs. J. Brown.—Certainly, if the dwarf French Bean will succeed well under glass, grown in pots in houses or planted out in heated pits.—*W.*—Probably the *Acacia* has been allowed to suffer for want of water at the roots at some time. Please give particulars of its treatment.—*B. G. H.*—The plants named can be sent back if needed, and be spotted in April, and can go out-of-doors for awhile at

about the end of June, if the weather is warm.—*Araba*.—We should think that the cause of the leaves curling up is excessive drought at the roots. By all means sponge the leaves to remove dust.

Catalogues received.—*Vegetable and Flower Seeds*. Mr. Alexander Finlayson, 42, Abchurch Lane, Southampton.—*Seeds for Spring*, &c. Messrs. Tom B. Dobbs and Co., 32, Queen-street, Wolverhampton.—*Descriptive Spring Catalogue*. Messrs. W. Smith and Son, 18, Mark-lane, and 1 and 3, Hadden-street, Altrincham.—*Reliable Seeds*. Messrs. Dehbi and Dixon, 22, Oak-street, Manchester.—*Garden Seeds*, &c. Messrs. Hogg and Wood, Cobham, N.B.—*General Seed Catalogue*, &c. Messrs. Vilmoren-Ambreux and Co., 4, Quai-de-la-Mégisserie, Paris.—*Farm Annual and Seed Catalogue*. Messrs. W. Atlee Burpee and Co., Philadelphia, U.S.A.—*Seeds*, &c. Messrs. Richard Smith and Co., Worcester.—*Seeds and Plants*. Messrs. Sanson, 8 and 10, Portland-street, Kilmaeock.

POULTRY AND RABBITS.

5466.—**Poultry keeping.**—I shall be very glad indeed if "Boulding" could favour me with some information how I can improve the stock of the poultry about my farm without going to very much expense, as I am under the impression that poultry should be made to pay us better if we understood more about the most suitable kinds to breed from. I keep about 60 hens, principally of the Borking and Minorca breeds, and rear about 100 chickens each season, about three quarters of which are sold for table use. I get plenty of eggs during spring and summer, when they lay about 100, but when they are worth 4s. 6d. and 2s. a dozen, the number sometimes does not exceed a score in a week. The fowls are fed with soft food (bran, sharps, and boiled Potatoes or Turnips) first thing in the morning, and then with light chaff or barley in the afternoon, are well housed, with plenty of water and liberty to go where they like. (I do get so many suggestions from various people what kind of a cock should be used that it is difficult to come to a decision. Some recommend a Houdan, as the hens are good layers and good table birds; others say, in my means, use one as there will sure to be trouble with the hens not being good sitters; others say a Brahma cock, as you would get a big chicken and plenty of winter eggs; but no is said, on the other hand, as the chickens are not good table birds. What I am inclined to try is an Indian Gamecock (although I have never seen one), mixed with a dozen of my best Borking hens (keep separate from others), if such a cross would produce chickens of a big size and pullets which would be good layers, as the hens are good layers, but that this cross makes a good chicken of fine flavour, but can get no information regarding the other two points. I recently saw a native Wyandotte cock, and like his appearance very much, as he looks a substantial, heavy fowl, and is said to make a good table fowl of large size, and the hens being capital layers, so will be much obliged if you could tell me which of the two crosses would produce the biggest table fowl and the best laying hen. Feather-legged fowls do not, as a rule, do well, as the soil is rather dry and cold. Should I mix a few Bantams as well, or lay eggs and hatch them?—*SCOTCH FARMER*.

BIRDS.

5467.—**Management of a Parrot.**—I should be much obliged if anyone would inform me what to do with a Parrot that is always tearing out the feathers from her breast? At the present time her breast is quite bare. She is fed principally on Canary-seed, bread, and a bit of meat now and then. I put some paraffin and oil on her breast to see if this would deter her, but she only turned pink and would not speak for several days. She has plenty of water to bath in, and her cage is kept beautifully clean. I am quite sorry to see her poor breast.—*POULTRY*.

"Gardening Illustrated" Monthly Parts.—*Price 5d.; post free, 6d.*
"The Garden" Monthly Parts.—This journal is published in neatly bound Monthly Parts. In this form the colour plates, &c., are bound up, and the text is printed in reference previous to the issue of the half-yearly volumes. *Price 1s. 6d.; post free, 1s. 9d.* Complete set of volumes of THE GARDEN from its commencement to the end of 1893, forty-two vols., price, cloth, £20 12s.
Farm and Home Monthly Parts.—This journal is published in neatly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. *Price 5d.; post free, 6d.*
Hardy Flowers.—Giving descriptions of reports of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. Fifth and Popular Edition, 1s.; post free, 1s. 3d.
London: 37, Southampton-street, Strand, W.C.

STRONG STRAWBERRY PLANTS.—The Captain, Keen's Seedling, Hartsbill, Sir Joseph Paxton, Vicountess's Fruit, &c. President, Lexington, Numb. 50, 1s. 9d.; 100, 2s.; 250, 6s.; 500, 10s. 6d. carriage paid, root with order.—*JOHN TURNER*, Wetherby, Yorks.

PERNS, EVERGREEN.—12 hardy large-rooted Irish feather Ferns, in 12 sorts, 6s. for any place, 2s. 6d. free. 500 of Gentiana Ferns, 2s. 6d. Trade supplied. Catalogue of 500 new sorts of the Hart's-tongue Fern, 3d.—*KEBLEY*, Hallyvaughan, Co. Clare.

GENTLEMAN recommends good Gardener; good experience in hardy flowers, Roses, Carnations; age 32; married, no family; good character.—*G. BULL*, care Editor, 37, Southampton-street, Strand.

AGENTS WANTED FOR THE SALE OF NATIVE GUANO.—Best and Cheapest MANURE for all FARM and GARDEN CROPS.—**NATIVE GUANO COMPANY**, Ltd., 20, New Bridge-st., London, E.C.

A STRONG ACTIVE LAD of eighteen seeks a situation as Under Gardener, 34 years in last situation, left through no fault, but wishes to improve himself. Good character, Notafraid work.—*J. HICKETT*, Fishbeck, Herts.

WANTED.—A Partnership in a thriving Nursery Garden near large town, Yorkshire preferred. Good capital required, acreage, and amount of stock. Apply to *L. KELLY*, Green-lane, Frodingham, Liverpool.

EVERYONE WHO HAS A GARDEN, GREENHOUSE, OR WINDOW BORDER SHOULD READ A PAMPHLET, POST FREE.

HOW TO INCREASE THE FRUITS OF EARTH.

By G. H. WILKINSON, F.R.S., F.O.S., Trinity Col., Dublin. Contains full particulars of very remarkable discoveries relating to Plant Life. Shows how crops of vegetables may be largely increased, how flowers grown to perfection, and fruit-trees made to bear in abundance. Selections from Hundreds of Testimonials. Post free from **JAKEMAN & CARVER, Printers, Hereford.**

INVALUABLE TO GARDENERS, AMATEUR OR PROFESSIONAL. Just ready, strongly bound, 1s. post free. **WILKINSON'S ILLUSTRATED GARDEN ALMANAC AND FLORIST'S GUIDE** for 1894 contains the following original papers:—How to Make Garden Appliances Vegetables: their Culture and Importation Thomas Laxton, Gardener and Hydroponic Garden Work Throughout the Year Good Things for all Gardeners—Novels in Flower, Fruit and Vegetables for 1894, and a list of all Nurserymen and Seedsmen throughout the United Kingdom—London: **WAARD, LOCK, and BOWDEN**, Ltd., Stationery-square, E.C.

FIELD'S WALL-NAIL (Patented). **NO CLOTH NEEDED.** TRAINING DOME WITH EASE AND EXPEDITION. Many other advantages. Made in 4 sizes, and may be obtained as follows:—
Boat Mallocco, 6d. per lb. (plain); Anonked cast, 4d. per lb. (plain). Either make done with preparation, especially for tender subjects, 1d. per lb. extra.

S. G. FIELD, 51, WILSON ST., FINSBURY SQUARE, E.C. **GREENHOUSES.**

The cheapest and best finished in the trade; size 10 ft. by 7 ft. wide, including 2 1/2 in. glass, sashing, ventilating, tank for floor, and gutters, all complete, £4 15s., and 12 ft. by 8 ft. wide, £5 15s. Price lists free. Write for CATALOGUES. Horticultural Builder, TYLDESLEY.

NATIVE GUANO.

BEST AND CHEAPEST MANURE FOR GARDEN USE. Price £3 10s. per ton, in bags. Lots under 10 cwt., 4s. per cwt.; 1 cwt. Sample sent carriage paid to any Station in England, on receipt of P.D. for 6s. Extracts from 18th Annual Collection of Reports:—**NATIVE GUANO FOR POTATOES, VEGETABLES, &c.** H. BRICKWORTH, Potato Grower, Reading, used for potatoes, Dulcans, and Carrots; results: "Very good; never had better crop."—*J. A. Gardner, Gardener to Lord Portman*:—"A better crop of Onions I don't wish to have. I can thoroughly recommend it as a valuable manure for vegetables."
NATIVE GUANO FOR FRUIT, ROSES, TOMATOES, &c. R. D. CHAMPAIGN, Gardener to F. T. Colbeck, Esq., Polytechnic:—"For Cucumbers, Melons, Peaches, and Vines, it is my favourite manure. For Violets in frames, Chrysanthemums, and nearly all kinds of plants, we use it with excellent results."—*H. HIGMAN, Gardener, Royal Nursery, Wandsworth*:—"For some of my plants, it is the best manure at the price I ever had. Specially good for Camerarias and Tulips."
Orders to the **Native Guano Co., Ltd.**, 29, New Bridge-st., Blackfriars, London, or by Pamphlet, of Tyldesley, &c., may be obtained. **AGENTS WANTED.**

GREENHOUSES, FORCING HOUSES, VINERIES, FRAMES, &c.

HAWKINS' Perfection "air tight" System of Glazing in the best. No skilled labour required to fix glass or paint; no extra cost; all parts and much cheaper than any other. Sample double frame, 8 ft. by 6 ft., with 20 lights, painted three coats and glazed, for 45s. Note the marvellously low price for following substantially constructed houses: 100 ft. by 12 ft., 250 ft. by 12 ft., 400 ft. by 10 ft., 275 ft. by 10 ft. Several second-hand houses very cheap, 100 extra strong lights, 6 ft. by 4 ft., painted and glazed, 47 lbs.; worth double. Less for large quantities. Don't build glasshouses without first getting estimates (free) from **HAWKINS**, Horticultural Builder, Ainsford, Middlesex.

GREENHOUSES FOR THE MILLION.

WHY BUY RUBBISH? when you can get me. Four well-known makes erected in your own garden, from 6s. Estimates given on every description of Horticultural Buildings. Send particulars of requirements to—

WM. COOPER'S NEW YEAR'S GIFTS

FOR EVERY READER OF THIS PAPER.

IMPORTANT.

I RESPECTFULLY beg to inform all readers of this paper that the Second Edition (100,000 copies) of my Revised PRICE LIST, consisting of 400 pages, and about 1,900 Illustrations, bound in cloth, is now ready. I shall have much pleasure in forwarding to every person up to February 10, 1894, one post free, after which the price will be One Shilling each, post free. This List is the most complete in the Trade, and has cost several thousand pounds to produce.

A FEW OF THE MANY HUNDREDS OF

CONTENTS OF SECTION.

SECTION.	PAGES.
I.—Conservatories, Greenhouses, Vinerias, Herb. Hous., Plant and Forcing Houses, Frames, Pits, Hand Lights, &c.	17-54
II.—Poultry, Kennel, Rabbit, and Pigeon Appliances, &c.	65-98
III.—Rural Work.	99-134
IV.—Iron Buildings and Roofing, Church Furniture, &c.	135-178
V.—Heating Apparatus, Cooking Stoves, &c.	179-223
VI.—Horticultural Machines, Fortifiers, Insecticides, Worm and Weevil Destroyers, Suck-shades, Sells, &c.	223-246
VII.—Lawn Mowers and Edge Cutters, Tennis Mowers, Reapers, Rollers, &c.	247-268
VIII.—Horticultural Timber.	269-280
IX.—Horticultural Sundries, Wirework, Fountains, Vases, Statuary, &c.	281-342
X.—Vegetable and Flower Seeds, Plants, Hatch Beds, &c.	343-383

PRESS NOTICES

COOPER'S HORTICULTURAL BUILDINGS AND APPLIANCES.

We have received from Mr. William Cooper, the well-known "horticultural provider," of 755, Old Kent Road, London, S. E., a very complete, lavishly illustrated, and excellently printed catalogue of garden edifices and goods manufactured and sold at his works and emporium. We commend all our readers who possess gardens, and are properly interested in them, to undertake a pilgrimage to South London, and there inspect Mr. Cooper's show-ground and stock, and obtain a catalogue, if the issue thereof be not by that time exhausted. It is the most complete catalogue in that line possible to be conceived. "Who loves a garden loves a greenhouse also," wrote the poet-author of the "Task," and any requiring one of these—Mr. Cooper's express specialities—will find a varied selection of about 500 houses at the show-grounds adjacent to the manufactory in the Old Kent Road. Space fails us to even barely enumerate the departments embraced in this catalogue. Suffice it to say that anything and everything required for gardening is to be found in Mr. Cooper's large and varied stock.—*Carpenter and Builder*, Nov. 24, 1893.

HORTICULTURE.

Mr. William Cooper, the well-known horticultural provider, of 755, Old Kent Road, has just issued a voluminous catalogue of the goods he manufactures and supplies, which cannot fail to be useful to horticulturists, &c. Mr. Cooper believes this catalogue to be the most complete in the trade, and as it consists of nearly 400 pages we can quite believe this to be the case. It is priced at a shilling, and is cheap at the figure remembering the amount of useful information it contains.—*Buckley Heath Observer*, Nov. 11, 1893.

Mr. Wm. Cooper, horticultural provider, 755, Old Kent Road, London, has been good enough to send me his new illustrated list. It is a very handy book, and I have no doubt that Mr. Cooper is justified in claiming that it is the most complete in the trade. It would be a hard task to think of anything connected with the business which is not mentioned here, and the book also contains a mass of information about many other matters, for in it you can find prices and full particulars of hundreds of things, ranging from piggeries to tennis and cricket pavilions, from tobacco-juice to mission churches.—*Advertiser*, Nov. 23, 1893.

RECEIVED.

A REMARKABLE CATALOGUE.

We have received from Mr. William Cooper, 755, Old Kent Road, a copy of what must assuredly be the completest horticultural trade catalogue ever issued. Nearly 400 pages, containing 1,200 illustrations and an immense amount of closely-printed matter, afford descriptions and prices of everything which can be wanted in the garden, conservatory, and forcing-house, alike by the professional or the amateur. The prices appear to be exceptionally moderate.—*St. James's Gazette*, Nov. 21, 1893.

Mr. W. Cooper, horticultural provider, of 755, Old Kent Road, London, has transmitted to us a copy of his illustrated catalogue, which is as fine a work of the kind as any we have hitherto seen. This widely-known manufacturer of almost every description of horticultural production bids fair to make himself unrivalled in elegance of design, adaptability to purposes, and general excellence of workmanship. We should advise all horticulturists to apply for this catalogue, and give a trial to some of Mr. Cooper's excellent manufactures.—*Weekly Herald*, Nov. 17, 1893.

It is the most complete catalogue of the kind we have ever seen.—*Buckpool Advertiser*, Nov. 17, 1893.

WHAT MY CUSTOMERS SAY—

5, Hanging Birch, Rhodes.

DEAR MR. COOPER,—It is with very great pleasure that I write to inform you that I have received your valuable books all right, and I scarcely know how to render thanks enough to you for them. I am certain it is a great prize for me to receive such nice books as the two you have published, they are fit to be placed in the library, as they are so nicely bound and well printed. I could never have thought they would have been like they are; and I was very much surprised when I looked through them and saw that they contained so much and so interesting reading, as well as the engravings. I may say that I shall do whatever I can to spread your name in Lancashire, as well as give you an order or two. You are very well deserving of it I must say, and my friend thanks you very much for the one you have sent him through my name. Trusting that you will ever prosper in your business and do well, with regards, from yours truly, from Rhodes, Lancashire. WM. BENNETT.

We have received from Mr. William Cooper, 755, Old Kent Road, a copy of what must assuredly be the completest horticultural trade catalogue ever issued. Nearly 400 pages, containing 1,200 illustrations and an immense amount of closely-printed matter, afford descriptions and prices of everything which can be wanted in the garden, conservatory, and forcing-house, alike by the professional or the amateur. The prices appear to be exceptionally moderate. The Universal Provider of Westbourne Grove has long been known to be equal to any demand made upon him; but the Horticultural Provider of Old Kent Road appears to be likely to run him close both as to variety and good value.—*St. James's Budget*, Nov. 24, 1893.

Mr. William Cooper, the horticultural provider of Old Kent Road, has just issued a most exhaustive catalogue, price 1s., of the goods manufactured and supplied by him. The catalogue, which is neatly bound, contains no less than 383 pages, and nearly every page on the face of it has one or more illustrations, showing at a glance the particular article referred to—be it a cottage or a garden tool. Mr. Cooper's large steam works, which enable him to turn out all kinds of horticultural buildings and requisites at a very moderate rate, have been long known to the public, but until this catalogue is seen, few persons would believe in the extent of Mr. Cooper's operations. Besides manufacturing or supplying all kinds of buildings and utensils for the garden or country house, he also deals in seeds, shrubs, tubers, and bulbs, and the garden notes and calendar of work for the week, which form a part of the catalogue, contain a most useful fund of information for amateurs and others.—*South London Press*, Nov. 18, 1893.

The book is by far the most complete of its kind we have seen, and its contents have a very wide range, from the handsome conservatory costing hundreds of pounds, to the smallest article of the value only of a few pence.—*Advertiser*, Nov. 18, 1893.

Teeming with illustrations evidences the fact that Mr. W. Cooper is one of the most comprehensive merchants of the day.—*West Kent Advertiser*, Nov. 18, 1893.

The business is a most comprehensive one, and a visit of inspection will repay the trouble of a journey to Old Kent Road.—*West London Reporter*, Nov. 18, 1893.

WILLIAM COOPER, 747 to 755, OLD KENT ROAD, LONDON, S.E.

GARDENING ILLUSTRATED.

No. 779.—VOL. XV.

Founded by W. Robinson, Author of "The English Flower Garden."

FEBRUARY 10, 1894.

INDEX.

Adiantum Capillus-ven- eris 703	Dendrobium Pierardi .. 697	Greenhouse, untreated.. 686	Peach dropping its buds 703	Purple, late 702	St. James's Park, stump work in 796
Aurumula, good kind .. 701	Fern, a hardy, for the garden in window .. 703	Hope on a wall 701	Pea-trees for small gar- dens 703	Primulas, Chinese, treat- ment of 704	Sumach, the Venetian (Rhus typhina) .. 699
Ashes for the garden .. 693	Ferns, Maiden-hair, and Scolopendras 703	Iron fencing 704	Peas, broad-leaved .. 703	Pyropagata, a 704	Tomato-house, making a 702
Ash-pit, an 693	Scindulus 703	Lamp-br, a potager .. 704	Peas, growing 702	Questions and answers 704	Tomatoes for market .. 702
Aspidodras in pots .. 704	Ficus, brown spots on a Ficus r. hot-water appa- ratus 693	Laurel, Mountain (Kal- mia latifolia) 699	Peas, sowing 702	Rivini, Lucia 701	Tomatoes, growing .. 702
Aspidium acrostichum .. 703	Flora r. hot-water appa- ratus 693	Lilac, Persian 699	Pinks, eating 700	Rose, White Cluster .. 695	Tomatoes under glass for market 702
Asplen. China, fr. from scout 697	Foreing house 696	Lilium, best 701	Pinks, removing out- sides 704	Roses, Christmas .. 700	Tomatoes under glass for market 702
Bolton, roll, setting on .. 704	Fruit garden 696	Lily of the Valley, early Lily, best 701	Plants, blinding flower- ing 700	Roses, Moss 685	Town garden, work in the vegetable garden .. 696
Canaan, yellow 695	Fruit-trees, tooling out- sides of 703	Lycodes 697	Plants, cuttings of in loo- p 701	Roses, ornamental .. 695	Vine, management of a 703
Caryophyllus, Pom- peii 701	Fuchsias, multi-ally .. 704	Lysimachia Nummularia aurca 700	Plants for a narrow ben- ch 700	Roses, pruning .. 695	Work a week, the counting 186
Chimera for a wall, &c. 701	Hardy work 696	Moss on a humidus .. 701	Plants, frost-killed .. 703	St. James's Park, stump work in 796	Wireworms 695
Conservatory 698	Hardy work 696	Moss on a humidus .. 701	Plants, good for .. 695	St. James's Park, stump work in 796	Wireworms 695
Crocuses, birds eating .. 701	House, the Sea Lyme (Clypeus arenarius) .. 701	Palms 698	Plants, good room .. 695	St. James's Park, stump work in 796	Wireworms 695
Cucumbers in frames .. 696				St. James's Park, stump work in 796	Wireworms 695

ROSES.

PRUNING ROSES.

Now if we continue to experience mild weather, many readers of GARDENING will soon be thinking about pruning in the rosery. The best time for this operation varies so much, both on account of the season and extended area the Rose is now cultivated over, that no absolute rule is safe. Still, I would like to give a few notes of a general character, and to present them early enough to be of service to those who would be otherwise pruning earlier than my experience has proved advisable. My residence is in a warm southern county, but even here I do not prune until March—and quite the latter end of it. H. Perpetuals and H. Teas may be pruned then, but I would strongly advise leaving the Teas and Nisettes, also the Chinas and Bourbons, for a couple of weeks longer. If my readers who are anxious to get the best results, and have not had considerable experience in the pruning of Roses, will give a little attention to these dates, and at the same time bear in mind the relative position of their garden with my own, they can form a good idea of what will be the most suitable time for their own. I frequently leave mine a fortnight later than the time stated. Another most important point when pruning Roses is to be fully decided upon the following: Are we to have quantity at the expense of quality, or shall the two be combined as far as possible? Then there are two distinct styles of pruning, and although I have frequently touched upon both in my replies to queries it may be well to give a brief repetition in these notes. Perhaps I cannot do better than name a few varieties typical of those which need a specific class or style of pruning. Dullness of Belford and Abille, Bonair from the H. Perpetuals; Lady Mary Fitzwilliam and Comte Henri Rignon in the H. Teas; with Souvenir d'Elise Vardon and Comtesse de Nalailac out of the Teas, may be taken as an example of

MODERATE GROWERS, which always need rather severe pruning. These generally produce from one to four stout shoots from the base of the plant towards the latter part of each season. Let these be cut back to within a foot or so, and the rest of the growths thinned out, leaving a few of the stronger shoots about 3 inches. We now advance to

FREE GROWERS, of which I may cite General Jacquemont and Fisher Holmes, La France and Vicomtesse Folkestone, with Marie Van Houtte and Mme. Lambert as representatives from the three chief classes. In this case much depends upon the size of the plants. If large bushes, then commence by thinning out the centre and weaker shoots; next trim back the remainder to a length of 6 inches to 2 feet, according to the size and number of the shoots, the stronger shoots being less severely pruned than the others. In case of a very old plant, do not fear to put the knife into it pretty severely, especially towards the centre, if the wood is not quite healthy young wood to break lower down, and so remedy much of the bareness we frequently

notice at the bottom of some old favourites. The third class are

VIGOROUS GROWERS, like Duke of Edinburgh and Gabrielle Luizet from the H.P.'s, with Gloire de Dijon and Marechal Niel from the Teas, and such vigorous climbers as the Banksians. These do not need spring pruning so much as summer. We invariably get better quality and quantity from the extra stout growths of the previous year, therefore it behoves us to secure as much of this as possible. Seeing that the wood which has once bloomed is of little future benefit, it is better to remove it directly the crop of flowers has been realised. Generally speaking, these varieties are grown in beds or against walls. In either case we secure a greater quantity of bloom upon half of the amount of young wood when compared to that which bloomed the summer previous. The quantity and uniform show of bloom is also much heightened by training the growth in a horizontal position. In beds the plan is to peg it down to within a foot of the ground, or a few of the stronger branches may be allowed to arch over with their own weight of bloom and foliage. Upon walls it is easy to nail them in a slightly slanting position even if not horizontal. Always thin out the weaker wood from these strong growers as a first operation, and then simply remove the immature points. Finally, one had much better be a little late than too early in pruning Roses.

MOSS ROSES.

THESE are general favourites, especially as coat flowers; but although we have a large number of varieties, those really worth growing may be reduced to six. The Common Moss is one of the oldest Roses known, and was cultivated in this country as long ago as 1590. A pale-rose, with beautifully-crested sepals, this is still one of, if not the best variety. It must not be confused with the Crested Moss (or cristata), sent out by Vibert in 1827, but I fear a good many have been distributed of both kinds and under both names. The latter Rose is much the same in colour and habit, but more heavily mossed. It is really a crested form of the old Cahagne or Provence Rose, and is larger and more glolular than the common Moss. However, they are both very good. Blanche Moreau is by far the best White Moss Rose we have. By-the-way, the raisers of this grand variety (Moreau et Robert) would seem to make a speciality of the Moss Rose, for I note they claim no less than forty among a list which is just to hand. There seems to be a firm of Moreau et Robert, and one of Robert et Moreau; also two separate firms of Robert and Moreau, all of whom make the Moss Rose a speciality. But we are bound to say not with any great success, so far as sterling novelties are concerned, if the quality of fresh introduction is considered. Colina is a deep-crimson, with purple shading, very free blooming, and one of the best dark varieties. Baron de Wasseraer, a light-crimson, and Quatre Saisons Blanche, a perpetual-flowering white of the same form, will complete our list of the best. The two varieties bloom in clusters. There is a new Moss, Zenobia, sent out by W. Paul and

Son, which promises well; but it is large, and to my taste size detracts from the beauty of a Moss Rose. P. U.

5417.—Pruning Roses.—Prune the Roses mowed towards the end of March, according to the weather. If the season is early prune early; if late delay the pruning till the end of the month. Cut out old unhealthy wood, if any; small weakly shoots which cannot produce blossoms should also be cut out, and the strong shoots from which flowers can be obtained should be shortened back to from 6 inches to 10 inches, according to strength. If a few very fine blossoms are required cut in a little closer. —K. H.

The five varieties you name may all be pruned early in March. The two first are not quite so strong growers as the last three, and will be better if pruned a little harder. If you have any healthy growths over four feet, I would peg them down and so secure bloom from almost their whole length. When pruned, such growths only produce two or three blooms, whereas the other method will secure ten or a dozen. —P. U.

5301.—White Cluster Rose.—I think the Rose you describe is the White Banksian. The already sent this Rose very well, so, too, does the description you give of its buds and foliage. There is a variety among the Ayrshire Roses called "Aubrey" and "Myrtle-scented" which might be it, or Alcege Vibert from the Nisettes. You see, it is difficult to say exactly without seeing a portion of the plant. —P. U.

2578.—Wireworms.—I am afraid I cannot help you much in this case, as you appear to have a good quantity of the mould to deal with. If you only wanted a little for potting purposes you might put some of the mould in a hot oven and bake it, which would kill the insects, or you may spread it in the ground and pour boiling water over it to get rid of the enemy; but you would hardly care to deal in this way with enough of the mould for a Potato-bed. The frost will certainly not kill them if you do as you propose. I would not willingly use the mould in its present state for any purpose in the garden. You had better make up a slow fire in one corner of the garden and char the whole of it. There is no better plan of getting rid of the wireworms. Are you sure that the insects are what you suppose them to be? The wireworm is nearly an inch long, light-brown in colour, with a very tough skin. —J. C. C.

5418.—Yellow Carnation.—I suppose you refer to "Pride of Great Britain," which is being sent out by Mr. T. S. Ware, of Tottenhain. I have not tried it outside yet. —B. C. R.

A very large-flowered Yellow Carnation is named Pride of Great Britain. It is quite a Malmaison in character, large, and deep-yellow in colour. Unfortunately the calyx splits a good deal, but this is a failing of many kinds, especially those of such large size as this. I have only seen it in the greenhouse, where it is a strong-growing and free-blooming variety, but possibly it would succeed in the open. It can, however, scarcely be classed amongst

ORNA TAMPAIN

GARDEN WORK.*

Conservatory.

A sweet, humid atmosphere is essential to the preservation of plants in bloom, especially those which have been forced or pushed on by stimulants. This involves regular, steady fires at night and during damp, cold days. On bright mornings damp down the fires, and push in the shutters early, or else let the fire go out altogether and refresh in the afternoon. Sometimes, at any rate, this should be done in order to give the furnace a good clean out. Ventilate at every favourable opportunity on the south side of the house, but avoid cold currents, or the flowers will soon fade. See that there are no very dry spots in the borders where climbing plants are growing. Creepers and climbers which were pruned in autumn are now breaking strongly, and where the shoots are crowded some should be rubbed off before the growth gets into a tangle. The pruning of growing plants should be done when the finger and thumb can slip out the terminal bud. Nearly all plants will benefit by pinching in the leading shoots during growth to give symmetry. To keep growing plants in good condition, they should be frequently turned round, especially in this necessary in hothouse plants. Insects will have to be reckoned with now. The most troublesome at this season are greenflies. Where they come from in such immense numbers often puzzles amateurs, but half-a-dozen flies will stock a large house in a very short time, and to keep the house clear, an occasional fumigation should be resorted to. If no flies are visible, we may be sure a few specimens will be hidden away somewhere. Acanthias are very beautiful now. A. arvensis is a good kind for these who have only room for one or two. It submits readily to pot culture, and is very easily managed. After flowering is finished prune into shape, and about June or early in July prune out-tops to 12 in., and in February and March the plants will be removed and given fresh cuttings. Cuttings of the half-ripened young shoots will strike under a bell-glass in a shady part of the house in early lean and leaf-mould. But always in using bell-glasses in propagating let the inside of the glasses be wiped dry every morning. If this is not done the condensed moisture will cause the cuttings to damp off. When the flowers of Arabis late have the flowers and seed-pods at the same time. Nothing weakens a plant so much as producing seeds. Cuttings of winter-flowering Salixes will root now in a little heat. If a few cuttings are rooted most of the old plants may be thrown out, as young plants may be grown into large bushes in one season, especially if planted out in some open situation, and the leading shoots pinched occasionally. On the other hand, old plants of Eupatorium odoratum may be kept in good condition for years if pruned hard back after flowering and planted out in the first week in June.

Forcing-house.

Very high night temperatures are not, as a rule, desirable, and the thermometer raised but a few degrees at night is a high night temperature in an open one, and must be regulated according to the subjects dealt with. At this season very few plants are improved by a higher night temperature than 45 degs. Growth, or rather elongation, takes place chiefly at night, and when the night temperature is moderate, high, the shoots are long-jointed and weakly, and though growth may appear rapid, it really is not so. Cucumbers and Melons will do very well in a night temperature of 45 degs., and no harm will be done if the thermometer falls to 60 degs. at sunrise. It is far more important that the growth should be strong and firmly put together than that it should be merely lengthened out. With the increasing daylight more work will now be done under glass, and where a miscellaneous selection of plants is being forced, much care is required to keep everything moving along in its proper direction. Hardy plants intended for forcing should be established in pots, and should receive the first impulse in a lower temperature than the forcing-house. A fire at work may help on many things, and when the sap has been set in motion a shorter time in the warmer house will suffice for bringing out the blossoms. The forcing-house at this season will always be full, but it should not be unduly crowded, and some space should be taken for every plant having occasional fumigation with Tobacco should be given, so that greenfly or thrips never get a footing therein.

Unheated Greenhouse.

Double Wallflowers and White and Scarlet Intermediate Stocks are among the sweetest things for the cold house in spring, and may easily be grown to decent-sized specimens in 5-inch and 6-inch pots. The seeds are usually sown in July, and the plants grown steadily on in the open air till frost comes, and then sheltered in a cold pit or in an unheated house. Bulbs at this season are very often well done in a cold-house by the use of paper covers on very cold nights. Hyacinths, if the wood has been well ripened, will do very well without fire-heat, and though early flowers may be retained in a warm-house, the later blossoms are none the less appreciated. Very sweet are most of the Rhododendrons from the higher regions of India, and many beautiful hybrids have been raised from these which can be kept quite safely in the cold-house. The Tree-Panicles are almost too tender for full exposure in any but sheltered districts, but they are charming for the cold-house, and after the growth is a little hardened they may be plunged outside.

Cucumbers in Frames.

The present is a good season for making hot-beds for Cucumbers. The manure must be frequently turned and intermixed till it is rankness is drawn out. Where three beds are plentiful, a free admixture of these with the manure will absorb dangerous gases, and the bed may be made up with just one turn over. Beds for Cucumbers must be well put together, and should extend at least a foot on all sides inside the frame. It often pays better to buy the plants when the bed is ready than to raise them, as time is gained thereby. The Chamber frame is generally used at the beginning to bring forward early plants besides Cucumbers, and when this is so, special

care should be taken not to introduce any plant likely to be infested by insects. Green-fries in a Chamber frame, if not checked as soon as possible, must do harm, because the means adopted for their destruction are often injurious to tender leaves.

Orchard-house.

The buds of Peaches and Nectarines are now swelling even in cold-houses, and some of the early kinds are showing colour. Ventilate freely, but avoid cold currents. All inside borders must now be in a fairly moist condition, and the trees in pots must be carefully examined every alternate day. Thus will do very well with Franche, but Peaches and Apples should be kept in a house by themselves. Apricots are not, as a rule, so good in a mixed house as when in a department can be given up to them. I have seen splendid crops of Apricots grown under glass, and the trees do best planted out, and the ventilation must be as perfect as possible. Anything in the shape of a dudness is fatal to the Apricot blossoms.

Cold Frames.

There are now very spare frames at this season, as they are usually filled with Violets, Cauliflowers, Strawberries waiting for forcing, Catechuria cuttings, Carnations, Anemones, &c. As regards the latter everything in the nature of dry should be renewed promptly, and a light top-dressing will be useful, as the plants will soon be showing flower.

Window Gardening.

Moss will now be very prominent. A little green Moss over the soil in the pots gives a neat appearance without doing harm. Tullips may be taken out of the pots, if required, and planted thickly in vases or jars in Moss ash-tray. The Blue Scilla and the Chionodoxa will do well under this treatment. Cut down heavy plants of all kinds, and put in cuttings.

Outdoor Garden.

Thick beds of Lily of the Valley may be thinned now by cutting out pieces 6 inches wide at suitable intervals, the pieces taken out to be re-shed and planted elsewhere, or the pieces, if lifted carefully, may be forced in a frame, and when the flowers have been gathered the roots may be planted out. The hot-bed system of forcing Lily of the Valley is a cheap and expeditious one when the clusters of roots are four or five. The bed is made up in the same way as one would make up for Asparagus, or Potatoes, or French Beans. The clumps of Lily roots are placed close together on a layer of soil on the bed, and the intervals between the clumps are then filled up with fine light soil, but should be chiefly used. A soaking of warm water through the root soil so often all down. The frame is matted up till the lilies begin to move, which will be in a short time. Now that the lilies are running through, the borders should be forked over to open up and sweep the soil, and a general water-bath of these fibrous plants are established with old manure in autumn, and where this has been done the manure will be tacked in. But where no manure has been used, a top-dressing of some kind can be given if necessary, and many flowering plants require more liberal treatment than they receive. Many of the large overgrown roots of herbaceous plants will require dividing. Coarse-growing things should not be allowed to overshadow plants less robust in habit. There is generally some little work of this character to do every spring. Lilies of the Marston and Their species may be planted. It is better to plant in good-sized groups than to put in single bulbs. Plant three inches deep, and mulch the surface with old cow-manure or leaf-mould.

Fruit Garden.

I have no doubt there is still some fruit-tree planting to do. It is better, at present, to plant earlier, but we are all more or less the victims of circumstances. Either the soil has not been ready or some other cause prevents the trees being got in at the best time, and therefore the work has been delayed. But I would rather plant in March than leave the work till another season, as though no great progress may be made, the trees will be making roots. There is some difference of opinion as regards cutting back young trees after planting. Those young trees inserted directly for planting with bare roots must be cut back to 4 ft. up the heads, and the cultivators leave the cutting back of hot-planted trees till the following autumn; but all trees planted before the end of November should be cut back the following spring. This only refers to young trees which are not well furnished with branches. I have bought trees which have not required cutting back at all after they came into my hands, simply because they had been cut back in the nursery, and had formed well-balanced heads, well furnished with branches. Some people start with the idea that all trees from the nursery must be cut back, and mistakes are often made which throw back the work of the trees. Aelous may be started in hot-beds now if there is likely to be plenty of manure. Head back any trees intended to be grafted, and cut off succulent grafts and lay in under a north wall or fence. The orchard-house should be put into condition for starting. Even without fire-heat, Peaches and Plums under glass will be on the move.

Vegetable Garden.

Rhubarb may be divided and new plantations made. It is usually advisable to cut the roots up too small, unless stock is very scarce. Plant in rows 4 feet apart, and make the soil deep and rich. Strong-growing kinds like the Victoria should be allowed more space. Six feet between the rows will not be too much. I was talking to a Dutch grower near a large town some time ago, and I think, from information received, that Rhubarb, when properly managed, pays better than most things. Where there are glass-houses or rough pits warmed with manure, Rhubarb may be easily forced. The second crop of an early variety sheltered with pots or tubs comes on very quickly at this season, and after the plantation is once started it does not need much to keep the plants in good condition. The roots lifted are usually cut up and used to make new plantations. It is perhaps difficult to say which is the most profitable early Potato. Major's Profile and Beauty of Bolton are largely grown in some districts. They are heavy croppers, and the quality when cooked is good. The old Ashlett, when true, or a good selection from it, comes in very early, and the tubers are well adapted for forcing. Carter's Emerald has been highly spoken of. It is time, generally, to start potatoes, to get Potatoes planted in such a way, so that

april, where it will be possible to shelter them on frosty nights. Plant Shallots, Underground Onions, and Garlic. Chives also may be divided and replanted. Make new plantations of Horseradish. Make holes with a crowbar on well-prepared ground a foot or so deep, and drop the sets in. E. HOBAY.

Work in the Town Garden.

It is a pity that Amateurs do not thrive better in town air; they are so pretty, free, and generally useful. Many of our amateurs are well away from the London smoke, and planted in a border or large box, or even grown in good-sized pots in a warm-house. Amateurs bloom profusely all the winter through, and, indeed, almost all the year round. In a smoky atmosphere the plants grow fast enough, but only produce a few straggling blossoms in July or August, and hence are only of use as foliage plants. The late-flowering kinds of Eucaris are now in full beauty, and are most useful as cut-flowers as well as pot plants. These are far better town plants than the Eranthis or Hyacinths. The young stock of many about 2 inches long will strike almost as freely as Potatoes in well drained pots or pans of sandy loam and peat; and young plants so obtained will, if grown up freely, make nice flowering stuff in 5-inch pots by next Christmas. The old plants may be potted up into large sizes, and in this way soon make large specimens, which are far more profitable for cutting from than small plants. The growth must be persistently stopped at the second or third joint until about the end of July, or the plants will flower prematurely. Begin striking the cuttings of Zonal Marigolds ('Zonals') as soon as you can get them; they root best standing in or near a hot-water pipe or warm fire, and with very little water after the first watering in, until roots are formed, when water must be given. Plants struck now and potted in 5-inch or 3 1/2-inch pots in April will make nice stuff for bedding or for shading window-boxes in June. Six seeds of Lobelias, Hollyhocks, Verbenas, and Pelonias at once - that is, where a temperature of 55 degs. to 60 degs. can be maintained, otherwise better wait another month or so; but it is better to sow early if possible and let the plants take their time. Petunias are grand things for town gardens, especially where the soil is light. Now also seed of Nicotiana glauca to bloom in the summer. R. C. R.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from February 10th to February 17th.

Several seeds of various subtropical plants, including the Purple-headed Caster Oil (Gilliesia), Aralia latifolia, Ferdinanda chinensis, and the Variegated Tree-Mallow. They will be brought on in the hot-bed till well established, divided a lot of Cammas, and potted the roots to start them slowly for planting out in May. I have sometimes thought when they plant them out; but, on the whole, it is better to stir them and bring them on slowly in the late Peach-house, where the growth will be rapid. If planted in sheltered places and well supplied with water, such tropical plants soon make progress. A few things may be raised from seeds besides those named above. I have used Solanum in variety, including the Silver-barked variety, Solanum marginatum, which makes a very ornamental group. Thinned Grapes on early Vines. Disbudded Peaches in early houses. Thinned off some of the Peaches which have set thickly on the underside of the branches. Fumigated Rose-houses as green-flies have made their appearance on the young shoots and flower-buds. Started a new plantation of Horseradish in a trench made in a piece of recently trenched ground with the crowbar a foot or so deep, a piece of root with a crown attached is dropped into each hole, and a little fine, rich soil is rammed in. During the summer the crown will work out through the hole and form a long, straight, root-stock. Always when digging Horseradish the crowns are saved for planting. Sowed Chamber and Melon seeds, also seeds of a good strain of Tuberosa Bergomas. Potted out some of the seeds of Scotch and White Grandmas, also a lot of good mixed Zonals for pot culture. Started on Potatoes struck last August, and which have been growing steadily all winter. The spring-struck stuff cannot overtake these, and for early bedding cuttings are always struck in August. Sowed Celery in boxes, white and red. Potted off Lobelias. These are always sown in autumn, and then they get strong enough to be forced. Cleared out a few Asparagus roots which had been forced. Placed in the house a little fresh loam to mix with the lighter soil in which the Asparagus had grown, and planted the frame with Ashleaf Potatoes which have been started in pots for the purpose of filling frames as they become vacant. Sowed a collection of Hollyhocks in boxes and placed in ainery to start the seeds. The strongest plants will flower in the late summer if helped on a bit. Sowed a number of sperminum Freesias; eighteen bulbs in 5-inch pots, where nearly struck and produce good specimens, and makes some effect in the conservatory. These plants have had no forcing beyond protection from frost in a cold frame house.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved on the best material and will appear in due course in GARDENING ILLUSTRATED.

* In cold or northern districts the operations referred to in under "Garden Work" may be done from day to day in a fortnight later than in the south, with similar results.

ORCHIDS.

DENDROBIUM PIERARDI.

In reply to "B. S. R.," "Surreyite," and others, this Orchid is named after M. Pierard, a Frenchman, who found it, and by whom it was introduced into the gardens of England. It is a common plant in India, being widely distributed throughout that country, but it is particularly common in the forests in the Sunderbunds of the Ganges, from whence it was originally imported. Hence, as may be supposed, it requires strong heat and abundance of moisture in order to produce strong growths, and I have frequently had this plant produce stout stem-like pendulous bulbs some 5 feet or 6 feet in length. When fully grown the plant should be dried off and kept considerably cooler than during the summer. This will speedily cause the bulbs to swell up, and the leaves to shrivel and fall, as the plant is deciduous and loses all its foliage before flowering. Early in the season the flowers will begin to show all along the stems. These, mostly borne in pairs, are of a creamy-mauve, or cream-coloured in some forms, the lip large, downy, and of a soft sulphur-yellow, bearing a few purple streaks at the base. The plant should be grown upon a block or in hanging-baskets, as being a pendulous kind (see illustration), it will not thrive if made to grow upwards. The baskets should be well drained, and be filled with good fibrous-peat and Sphagnum Moss. The plants may be grown in the very hottest place possible to put them, always being kept well supplied with water during growth, but during winter a temperature of between 55 degs. and 60 degs. will be ample. There are several varieties of this Dendrole, some of which are very inferior. One of the best is *D. l. latifolium*, which produces fine flowers rather more freely than is the case with the type. M. B.

LYCASTES.

It is some long time since I promised "C. Bevis" that I would say something respecting the various plants in this genus, and now I undertake to do it as they will be waking up into growth again and will want repotting before coming into bloom. They will require a slightly warmer house than the *Odontoglossums*—that is, if these plants are kept cool—because I think where the temperature ranges from 45 degs. to 48 degs. it is ample for *O. Alexandrae*, but the *Lycastes* like it a little warmer in the winter. These plants enjoy a liberal supply of water during the growing season, and even in the winter I do not like to let them remain dry long together, just enough water being given to keep the bulbs plump. The plants should be shaded from the effects of the brightest sunshine, but still they revel in light with an abundance of air circulating amongst them. The pots should be well drained so that no stagnant water remains about their roots, using for soil good brown peat-lime and Sphagnum Moss. In potting I like to have the plants slightly elevated above the pot's rim, but some people prefer to pot them about level; but I think these Orchids are not very particular in this respect so that the young growths are free. Mr. Skinner used to say that *L. Skinneri* would grow in the dwelling-house without fire-heat at any season, but I have found it to be a plant that likes more warmth than any of the species. I do not think that there are any of them which do not thrive better with a little warmth. The following kinds are amongst the most beautiful, and most of them are reasonable in price and easily obtainable by all growers.

L. AROMATICA.—This is a small-flowered plant of a rich, clear yellow colour, but its chief recommendation lies in the beautiful warm aromatic odour which its flowers give off, and which renders them much in favour for gentlemen's buttonholes. It is free in flowering, and I have before me now a photograph which was sent me last year by a friend of a plant bearing one hundred flowers. A single flower is enough to put into a room with other cat blossoms, and also for a buttonhole bouquet, with just a little bit of some sort of greenery to afford relief. The plant sheds its leaves, for the most part, in autumn, but I think this comes about through its being kept too dry, and I like to see

this *Lycaste* so grown that a few leaves remain green on it, as they help to set off the clear, rich yellow of the flowers. It is a plant which I do not think has ever been lost since it was first introduced, which is now upwards of seventy years ago. It comes to us from Mexico.

L. PRESENTA is another yellow-flowered plant which is sometimes, but erroneously, called by the same name as the last. It differs in its much larger size, also in having a large blotch of very dark blood-red at the base of the rich orange-coloured lip which gives it its name, and in the lip being differently shaped, beside which the plant is a very much stronger grower, with stouter and larger bulbs and leaves; in fact, no two species can be more distinct, and the one distinction which might serve to a blind man to distinguish it by its entire want of any odour. The bulbs are some 2 inches or 3 inches high, bearing a pair of leaves some 18 inches long, with flowers as much across as the bulbs are

Dendrobium Pierardi.

high; these blossoms are deep-orange-yellow, stained at the base of the lip with deep sanguineous red. This plant comes from Guatemala, and also from New Grenada, and it was first sent from Guatemala by Mr. Skinner just over fifty years ago.

L. COSTATA.—This is a stronger grower than either of the preceding; indeed, it grows to an immense size, and it flowers are of a uniform creamy-white, with a slight stain of yellow on the lip. This plant, it would seem, has been figured under the name of *L. Barringtonia*, but it is the same as *L. costata*; the flowers are sweet-scented after dark. It was introduced to us from Peru just forty years ago.

L. DARRI is an elegant species, but it has been east on one side by many growers to make way in some instances for less ornamental plants. It was introduced by the Messrs. Loddiges, of Hackney, between sixty and seventy years ago. With the general aspect of a

Lycaste, the sepals and petals are green, spotted (in some forms freely) with bright-reddish, the lip being streaked with red, and having yellow on the disc. I saw in Mr. Snee's garden last year a green form of this flower, and at Sir Trevor Lawrence's I also was fortunate enough to walk in one day when the lovely variety known as *punctatissima* was flowering, the sepals and petals of which are a greenish-yellow ground colour, heavily spotted all over with red and reddish-pink; petals, white, similarly spotted, but more sparingly; lip, yellow. I have been induced to name this variety from its extreme beauty, but it is very rare. It may crop up from amongst any importations of *Orchids* from Mexico.

L. MEASURESIANA.—This is supposed to be a variety of *L. plana*, and if so it is a very beautiful one. For a long time it remained scarce in collections, but at last it was introduced in some numbers, so that it is now more frequently seen. It has the general appearance of the species. The flowers are freely produced, and are extremely handsome. The sepals are olive-green; the petals and lip are white, profusely spotted and blotched with bright-purple, saving the margin, pure clear white. It comes from Bolivia.

L. SKINNERI.—This species appears to be the grandest of them all, but so extremely variable in colour that I cannot describe it. The flowers are very thick and waxy in texture, the broad spreading petals being white or rose colour, from which they vary to quite a bright-crimson; the petals, which are much smaller, and stand erect, forming a hood over the lip, are always much deeper coloured; lip, red or crimson of various shades, mottled with white in the variety *alba*. The flowers are of the purest-white, saving a tinge of yellow on the disc of the lip. Another fine form is called *armeniaca*, and in this the flowers are pure-white, having a blotch of apricot-yellow on the lip. This makes a fine contrast, and is a very beautiful variety. There are numerous forms of this species named, but they only differ in colour, and it is so variable that no two plants from an importation may be expected to turn out exactly alike; but all of them are exceedingly easy to grow, and they flower very freely, making for home-decoration one of the most lovely displays imaginable. I hope "Miss B." will be induced to take these plants under her care now.

MATT. BRAMBLE.

5356.—China Asters, &c., from seed. —This is the best time to sow Asters, Marigolds, and similar annuals if desired to flower early; but if late defer sowing another month. A cold frame is as good a place as need be desired, for if shut up closely a good deal of solar heat will be enclosed to hasten the germination of the seed, and after the seedlings are above ground they require plenty of air on fine days, so as to harden the growth previous to planting in the open air. I raise quantities of these in boxes, and when they are large enough to handle they are transplanted into the soil of other cold frames, about three inches apart, making splendid plants.—J. G. H.

—Asters and African and French Marigold seed will vegetate in a cold frame, although it will not do so quite as well nor so quickly as over a hotbed. The seed should be sown in March. Let the frame be well exposed to sunlight, and keep the lights rather closed until the seed vegetates.—J. D. E.

5415.—Gladolus seed.—The plan I have always adopted with seed of *Gladolus garlucensis* is to sow it in flower-pots, about fifty seeds in a 7-inch pot. Plunge them in a hot-bed and the young plants will appear in about ten days. The seed is sown about the first week in April, and as the plants appear above ground admit air more freely, so that by the end of the season they have made good growth in the frame, or, indeed, they may be removed to the open air about the end of May, and if carefully attended to as regards watering they will form nice plants by the end of the season, with bulbs from the size of a small Pea to the size of a Filbert. Plant these bulbs out-of-doors in March, and although they are so small nearly the whole of them will produce strong flower-spikes.—J. D. E.

Original sources of these generally sow the seeds in a prepared bed. The strongest bulbs will flower the second year under ordinary circumstances, and in some cases the third year. —E. H.

HOUSE & WINDOW GARDENING.

GOOD ROOM PLANTS.

PALMS.

AMONGST the best plants for rooms are the Palms in a small state, which are always stately-looking and attractive, and cannot be well misplaced. They are also very enduring, and will live and thrive where many plants of a less hardy nature would die. Another thing much in favour of them is that they require but little root-room, and are therefore all the more handy for vases, into which they can be placed without taking them from the pots. In such cases where this has to be done I have never found anything equal to Moss for placing round the ball, as that absorbs the water gradually, and keeps the plants nicely moist. The most desirable kinds of Palms for the purpose referred to are the Kentias, such as *Behourea*, and *Areca lutescens*, the last-named being very graceful in habit, and having rich-yellow stems that show up in fine contrast with the green of the foliage. *Latania borbonica* (here figured) in a small state is also a good sort to have, and so is *Chamaedorea*

A good room Palm: *Latania (Livistona) borbonica*.

gonenua-furmis, an excellent plant for small pots, and *Chamaerops Fortunei* will stand any hardship. B.

WINDOW BOXES.

5386.—There will not be much danger from drought at a north-east aspect, the morning sun probably going off before eleven. Wood is the best material to use for the five boxes, and they may be made at almost any rate from a few pence each to ten shillings or more, if highly ornamented. Good Elm boxes, the width of the window-sill, merely neatly varnished at the front edges, and painted (two coats thick) dark-green will probably cost about seven or eight shillings each if 6 feet long, but this great length may increase the expense, as wood becomes dearer in large pieces. In this case two smaller boxes would be cheapest. It would be well to go to a respectable carpenter, and ask him this question. Six feet is an awkward length to manage, too, in getting the boxes into position, and it is therefore better to have two of three feet each. There should be small wedge-shaped bits of wood nailed at the bottom to keep the boxes level, as window-sills usually slope upwards, and there is no necessity for holes being bored for drainage, as moisture evaporates very quickly from a box, and with good drainage holes are better avoided. The boxes should be at least 10 inches deep, and a foot will be better, as allowing 2 inches for cracks and ashes at the bottom. A handy man can easily construct window-boxes by selecting square boxes at the grocer's (about 2 feet by 4 feet, and a foot deep), and sawing them exactly in half, when half the cover will be found to fit into the back, and can easily be secured by adding the wedge below, and painting the boxes outside only, and about 2 inches over the inner

edge. If well covered with trailing plants such boxes look quite as well as those which cost much more, the price of these being about one shilling each. Plants growing in window-boxes have little room for their roots, as they should be thickly planted; therefore, they must have a good rich, light compost to begin with, consisting of loam, leaf-mould, manure, with a little sand, and should be top-dressed as the soil shrinks, liquid-manure being also given when the plants are in bud, once or twice a week. Soot-water is excellent liquid-manure, and can be easily made by putting a little soot (brushed from the chimney) into a coarse canvas-bag, tying it securely with string (yet not so tightly pressed together that it cannot shift), and placing it in a pan of rain-water, the surrounding water only being used in a thin, clear state, and renewed again and again by occasionally stirring the bag of soot with a stick, until most of the soot has been dissolved. It is not possible to have one set of flowers which will bloom continuously in spring, summer, and late autumn, and if no change is to be made only small shrubs or English Ferns can be grown in them. The best creepers to run up strings or

wires and form an arch at the top are *Tropaeolum canariense* (with masses of bright-yellow flowers), *Tropaeolum Lobbianum* (earmine blossoms), or the common Yellow and Red Nasturtiums; Major *Cucurbitaria* would do well here, too, and make wreaths of exquisite blooms in autumn; *Lophospermum scandens* (pale-pink, bell-shaped flowers, with handsome foliage), and *Maurandya Barcayana* (purple) are less common and very beautiful in effect. For trailers to hang over the box, Ivy-leaved *Pelargonium* ("Geraniums"), Blue *Lobelia*, Money-wort (with lung, trailing growth), Mother of Thensands (*Saxifraga sarmentosa*) with rich-dark foliage, Old *Pinks*, cut down in spring, and allowed to form hanging sprays, and *Nierembergia gracilis* are all excellent, with a row of drooping *Double Begonias* (tuberous) behind them. These can be bought specially for baskets and windows, those which have heavy hanging flowers being the best for this purpose. The back row of plants may consist of *Zonal Pelargoniums*, *Margarites*, *Petunias*, *Heliotropes*, &c., arranged to suit the tints of the other flowers. All these things are best put out at the end of May for the summer display, but "H. Ormonde" may have nice sturdy seedlings of Dark-bronze or Crimson Wallflowers, Forget-me-not (*Myosotis dissitiflora*), clumps of *Daffodils*, *Double Primroses*, *Double Daisies*, *Auriculas*, and late bulbs, put in at once, and exchanged for the above when they have done blooming in May. In the autumn *Asters* may be used to fill up gaps where plants have gone out of bloom, and dwarf *Chrysanthemums* will carry on a bright display until the frosts cut them off, after which small shrubs of bright-berried things, such as *Mahonia* (*Berberis*), *Aquifolium*, with purple berries and yellow flowers, *Cotoneaster microphylla*, *Skimmia*, and *Aucuba japonica*, with neat plants of *Laurustinus* (which flowers

in winter), will keep the boxes bright in winter; or bulbs may be put in—*Tulips*, *Crocuses*, *Hyacinths*, *Narcissi*, *Scilla sibirica*, &c.—to make a brilliant display during the early spring. For bow-windows, small boxes to fit each division are preferable to one continuous box, for reasons before given. The well-doing of window-plants depends largely upon the daily attention they get, constant supplies of water being necessary. If the boxes are once neglected, so as to become almost dry, the whole beauty of the arrangement may be destroyed; the owner's daily attention should be given to them for a few minutes, a few servants can be trusted to remember their needs, or supply them fully during the summer months. J. L. R.

5312.—**Heating a sitting-room.**—There are so many varieties of heating apparatuses advertised in GARDENING that it would be invidious to select any special one. At the same time "A. Saunders" should understand that those of which hot-water form a part are the best for plants; although those which generate moisture from the air are almost equally good, as there is no smell with them when used with a good lamp, and one of these throws out a considerable heat in the writer's hall. Any heating apparatus for a sitting-room should be easily movable, and the best position for it in a sharp frost will be between the window and the plants, so as to prevent the freezing air from reaching them. If a small hand stove be selected, a pan of water should be placed over it on an iron stand at about 8 inches distance from the top. This will prevent any injury to the plants from dry heat, but these stoves when heated by a lamp must be carefully regulated and have enough oil to last till morning, as they give out poisonous fumes in going out or if they flare up high.—L. R.

5408.—**Hyacinths in glasses.**—I am afraid *Hyacinths* which have been grown in glasses will be of very little use to anyone who has no garden; but they might be transferred from the glasses to boxes of soil and left there to ripen. Possibly they might come in useful for window-boxes in the future if taken care of, but they will only lead to disappointment if used in glasses again.—E. H.

— I think it would be wiser for "Amateur" to throw away the bulbs after they have bloomed. *Hyacinths* are got to the highest state of perfection before being imported, and under the most favourable conditions are of little use a second season. An "Amateur" does not possess a garden they would be of less service still. My own are planted in a warm situation and allowed to take their chance. They often flower fairly well late in the spring, but never produce such grand spikes as I got the first time, whether grown in soil or water.—P. U.

5422.—**Brown spots on a Ficus.**—Sooner or later the bottom leaves will fall from the *Ficus*. When the roots, from any cause, have become unhealthy the leaves may fall prematurely. Too much or too little water, want of cleanliness, or the atmosphere much contaminated with gas will cause the leaves to drop. The brown spots may be caused by drops of cold water destroying the tissues.—E. H.

— There are many causes of these, but I am inclined to think yours is either from drought or cold, perhaps both; or it may need repotting, the old soil being completely exhausted. If you were to show it to the nearest gardener or florist, he would doubtless be able to say the cause and suggest the best remedy.—P. U.

5411.—**Growing *Lilium auratum*.**—It will be the best plan to pot the bulbs and plunge the pots over the rim out-of-doors in some open material; this will cause roots to push out and growth to be made, and if the plants can be kept in a greenhouse or a frame until the flowers are about to open, they will do much better than in the window of a bedroom. In fact, I would rather grow the plants in a sheltered place out-of-doors; but, of course, there is the pleasure of watching the plants grow; in that case, they may be put into the room as soon as they have grown a few inches. Keep near the glass, and give plenty of air.—J. D. E.

— If the bulb is 3 inches in diameter a 7-inch pot will be large enough, measuring from the inside. Place half-a-dozen crocks at the bottom, covering them with some rough parts of the potting compost on fresh leaves, with a view to keeping the drainage in perfect condition. If the fine soil runs down among the

crocks the passage-way for water will be blocked and the roots placed in a stagnant state. Although *Lilium auratum* is a moisture-loving subject it does not appreciate too much water if the drainage is imperfect. Loam in three parts, with one part of half-decayed horse-manure, is a suitable compost. Do not fill the pot more than three parts full, only just covering the bulb. Roots will push from the base of the stem directly it commences to grow. These should be covered at once with equal parts of fibry loam and horse-manure, into which the roots penetrate freely. The soil should only just be kept moist until growth is well on the way, when abundance will be required, repeating the top-dressing as the roots show through the surface soil.—S. P.

5428.—**An ash-pit.**—If you had a glass light made to fit the pit, and the front and ends pulled down far enough to secure a gentle slope for the light, you might grow Cucumbers very well if you did not start with them till the middle of April. By that time the sun will have power to help you a good deal with its warmth. You will have to fill up the pit, of course, to within 1 foot of the glass, and if this can be done with stable-manure at the time I have stated, the bottom-heat rising from it would benefit the Cucumbers greatly, or you may fill the pit with soil and set out plants of Vegetable Marrows at the end of May. The growth of the Marrows may be allowed to hang over the sides of the pit.—J. C. C.

—Mushrooms in summer do better in a cool, shady spot, and later on in autumn or winter the deep ash-pit will not offer any advantages for Mushroom-culture; but if filled with warm manure and a frame placed over it, Cucumbers will do well in it, as would also early Potatoes or any other forced crop.—R. H.

TREES AND SHRUBS.

SHRUBS FOR FORCING.

MOUNTAIN LAUREL (KALMIA LATIFOLIA).

This is a capital shrub for gentle forcing, and small plants grown in pots may be had in bloom early in spring by introducing them into a warm, moist house, and keeping their roots well supplied with water. In a cut state the flowers are very valuable, but they are much best if left nesting among the bright glossy foliage of the plants on which they grow. This shrub is also excellent for planting in margins of shrubberies where the soil is moist and sandy. It also thrives remarkably well near lakes, where the soil is wet but well-drained. Its crisp, white-pinkish flowers possess a richness and beauty found in those of few hardy shrubs. The

Truss of flowers of the Mountain Laurel (*Kalmia latifolia*). Colours, white and pink.

best time to plant or pot up *Kalmias* is in September, but these operations may be very successfully done in February and March if the weather is open. B.

5471.—**Persian Lilac.**—I believe some people do succeed in getting *Lilacs* to flower after being dug up from the open ground and potted, but I never could get the same quantity of flowers from them as from those specially

grown in pots one year before forcing, and this is what you had better do in future. I, however, think that a part of your failure is due to starting forcing too early, and giving too much heat at first. No plant, whether a *Lilac* or a *Rose*, will submit to such early forcing after such a recent root disturbance as yours was subjected to. If you grow on your plant for next year treat it as you would a tender greenhouse plant up to the middle of May.—J. C. C.

THE VENETIAN SUMACH (RHUS COTINUS).

This, when in flower, always arrests the attention, because of its singular appearance, of even those who do not take a general interest in shrubs. On account of the feathery nature of the sterile flower clusters some call it the *Wig-tree*, a name by which it is perhaps better known than *Venetian Sumach*. It is an invaluable shrub, as it is attractive at a time when shrubberies begin to look dull and monotonous. It is always a dwarf, spreading bush, rarely more than 8 feet high. Its glaucous round leaves make a pleasing contrast to the reddish feathery clusters. It is hardy, almost evergreen, and grows in all kinds of soils, but must always have plenty of room to allow of full development. The bush here figured is a conspicuous object on the lawn at Marsham Lodge, Gerard's Cross, Bucks. G.

FROST-BITTEN PLANTS.

The frost awhile ago made it evident that greenhouses which are not efficiently heated are a delusion in so far as they are not often capable of resisting the frost of an ordinary winter. I am sorry to say that already it has come to my knowledge that many owners of unheated houses, and some that attempt to heat them with oil-lamps, have lost all their tender plants. One cannot but look upon the matter with a certain amount of regret, because I know in many cases amateurs have devoted much patient care in raising and tending their stock of flowers, and then to lose them in one short night by the cruel frost is, to say the least, disappointing to a degree; but so long as the owners of badly-heated houses court failure in this way, and ignore the advice of practical men, so long must they expect to meet with disappointment in the direction indicated, as not one year in ten can tender plants be kept free from frost in the ordinary greenhouse without efficient external covering, or some means of properly warming them. I do not wish to under value the use of oil-lamps for warming small greenhouses, because their management is easily understood, and convenient as well; but as compared to the cost of fuel for a small hot-water boiler, oil is quite as expensive. Seeing, however, that oil-lamps may be made the means of warming small houses in time of frost, it is a pity that many of those people who attempt to use them do not light them earlier in the evening, before the frost has had time to enter the structure. This neglect is, I find, the cause of much of the injury that has already been done by the cold. Those who have not the opportunity of observing the state of the temperature in the open air are surprised at the destruction the frost has made even in some heated structures. In the two days that include the 4th and 5th of the last month (January), the thermometer did not vary a degree for 32 hours, but remained stationary all that time at 15 degs. Fahrenheit, or 17 degs. of frost, which is the lowest reading I ever remember over so many hours. This being the case, there is not much reason to be surprised that the frost should penetrate into unexpected places. I have been consulted as to the proper treatment of a house full of plants that had been frost-bitten, the collection of plants consisting of such subjects as *Arum Lilies*, *Maiden-hair Ferns*, *Marguerites*, *Pelargoniums*, *Foliage Begonias*, &c., which had been killed down to the pots. The *Arum Lilies*, *Ferns*, and *Begonias* I advised should have all the growth cut down level with the pots, all the others of a less vigorous nature to have all the injured growth

removed at once, which will give a chance for the old stems to break into life below. Their recovery, however, depends more on the treatment they receive after the injured parts are removed. Plants in that condition should have at once and onwards a regular temperature of 50 degs., and the roots should not have any water for another month, or not until they show

OUR READERS' ILLUSTRATIONS: Venetian Sumach or Wig-tree (*Rhus cotinus*). Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. Frederick M. Fry, 14, Montague-street, London, W.C.

some signs of recovery. Even then the supply must be very moderate for several weeks. Such as recover and are fairly well furnished with leaves should be given some stimulating liquid. Where there are no means of heating the house, and the plants are frost-bitten, there is not much that can be done. Those of a succulent character, like *Pelargoniums*, should have the injured parts removed, and the roots kept dry for a few weeks. Hard-wooded plants under such circumstances had better not be cut back, but remain as they are until April, when it will be seen whether the injury is of a permanent character, and then have the injured growth removed if they are likely to recover. Their roots must not be allowed to get too dry, but the soil about them kept just moist. J. C. C.

Flues v. hot water apparatuses.—Although "L. C. K." does not actually say so, anyone not acquainted with the merits of a good flue as a heating medium—I am alluding to his notes in GARDENING for January 27, page 667—would naturally conclude that the flue was in fault, thus the frost got into the house and killed the plants to which he refers. I should not note the matter now, only I think the reader should be set right with regard to the utility of a flue, because I maintain that if the flue "L. C. K." refers to was at fault it is because it was badly constructed, or else indifferently attended to in regard to the fire. A well-built flue and a fireplace large enough to hold sufficient fuel will at any time defy frost, if ordinary care is used in attending to the fire, as well as the most expensive hot-water apparatus, and requires less attention. The reader will understand that I am not saying that the flue is better than hot-water pipes; I do not wish to do anything of the kind. The flue has done such good service in the past, and even now would be much better in some cases than the small hot-water apparatus, that I do not like to see a useful system of heating placed at a disadvantage without sufficient reason.—J. C. C.

OUTDOOR PLANTS.

CHRISTMAS ROSES.

THE planting of these should always be done prior to the pushing forth of new foliage. I am, however, aware that in some gardens where especial attention is accorded these plants they are successfully planted in the spring months as well as at other seasons. In all ordinary instances and where no especial home is provided for Christmas Roses it is by far the best plan where they cannot be planted in early autumn to do it as soon as flowering is completed. This will give them an opportunity of becoming well established before the prevailing winds of March and April arrive. Christmas Roses, that is, all the varieties of *Helleborus niger*, are best

A good Christmas Rose (*Helleborus niger*), showing habit of plant.

broken up into rather small pieces. Particularly is this the case where the plants have been allowed to remain long in one position. Very large plants with probably 100 or more flowers springing from each are exceedingly handsome looking subjects in the herbaceous border, or indeed in any position where such may perchance exist, but it does not follow that the finest flowers are always produced by these very large examples. On the other hand, I have found that the finest flowers are produced on two-year or three-year-old plants, coming from the time of planting and assuming that the plants have been broken up into pieces of not more than two or three crowns each at the most. Divisions of this size are quite large enough for transplanting, so that those possessing large specimens that have not been broken up for years could soon increase their stock of this invaluable winter flower. To those possessing such plants I would suggest that a portion be broken up or divided every year, as by so doing a continued supply of flowers may still be forthcoming as before. Where, however, the dividing and transplanting are deferred till the flowering is complete, the supply of bloom will not be interfered with. One thing is especially disastrous in

TRANSPLANTING CHRISTMAS ROSES, and this is attempting to transplant very large examples—that is, clumps of 2 feet or so in diameter. Though nearly twenty years have elapsed, I still remember an attempt to transplant some grand examples of these Hellebores in the lump as lifted, and though every precaution was taken and their new quarters ready prior to the specimens being lifted, it was all to no purpose. As a result, the attempt was an absolute failure and a lesson never forgotten. Every vestige of their grand foliage was lost leaf by leaf, and when in the early autumn of the following year I lifted them again to see if anything could be done, there was hardly a living root to be found in that huge mass, all of which was in the most perfect health when transplanted early in the previous autumn. The only remedy for plants thus reduced is to wash every particle of soil from them and remove the dead roots, afterwards dividing them into small pieces of a couple of crowns each and planting them in good soil in nursery beds. Prior to planting, allow the plants to become quite dry from washing by laying them on a dry surface.

and when planting freely dust them in the trench with fine charcoal. It will also be well to plant somewhat deeper than usual, so that the new roots which shall presently issue from the base of the crown shall have the advantage of additional protection. This is the more useful because the old decayed roots will be of very little service in restoring the plant to health, and for which it must depend on entirely new roots. This to some may seem a good deal of trouble to go to, but if the variety be a good one—as it was in the case of that I nearly lost—it will be well repaid, as in two or three years these divisions will have made nice flowering plants, and in much less time, of course, where the plants have not been subjected to a course of wrong treatment. It is at this season of the year that many who possess a

stock of flowering plants of these favourite Christmas Roses are tempted to lift and pot a portion of them for blooming under glass, and for purposes of decoration, either in a cut state or in pots, few plants can equal, much less surpass them. None are earlier or more enduring, and none more free-flowering or continuous. But where the plants are few in number and valued accordingly, the protection of a handlight will keep the flowers clean and pure, while no probable danger hangs overhead. All plants lifted and potted for flowering under glass will, if at all large, be best broken up into small pieces when flowering is over and replanted in good rich soil.

THE POSITION this section of Hellebores appears to prefer is one sheltered from cutting winds and also protected from hot sun. Distant shade is preferable to that provided by a wall, for example. An abundant depth of soil where the roots may be constantly cool is, however, the chief point. Given this, you may plant your Christmas Roses in a greater variety of positions with success than in those instances where depth of good soil is wanting. It is nothing unusual for their roots to descend to 2½ feet or 3 feet in the earth where the soil will permit, and it is more than probable that their roots will go down far deeper if an opportunity be afforded them. I mention this that amateurs who would desire to make a special feature of a few plants should in the first instance provide a fitting and a permanent home for these very desirable garden flowers. There are some excellent varieties in commerce at the present time, and a good one, if costing a little more primarily, will not require any more room than an inferior variety, while the satisfaction and pleasure obtainable by planting the best kinds will increase year by year, as will also the plants and the quality of flowers. A good form of Christmas Rose (*Helleborus niger*) is here figured.

E.

5110.—**Eaten Pinks.**—Both rats and mice will eat out the centre growth from Pinks and Carnations. The common brown field mice are, I think, the greatest enemies, and they are the most difficult to destroy, as they will not be tempted by an ordinary bait. I have caught two of them from the Red Glory (Reine Marie Henriette) is a suitable companion to the other. Black or Indian Corn that had been washed

for an hour or two in water. Put about three Peas on an ordinary pin, and then you can fix it securely to the trap. You may also examine the plants for slugs, as they are quite capable of doing the injury of which you complain.—J. C. C.

— I have had Pinks eaten off by field mice, but sparrows are generally the principal depredators. Thread lace over the plants to short sticks, so that the threads are 3 inches or so above the plants, is generally a sufficient protection. If this does not suffice, cover with fishing-nets. If not too much damaged they will recover, but the flowers will be small.—E. H.

5441.—**Climbers for a wall, &c.**—If you do not care to plant Ivy, you may select such Roses as Gloire de Dijon, Mme. Plantier, and Felicité Perpetue, but the best evergreen creeper is the Pyracantha. I should, however, prefer the Roses; they may not perhaps flower quite so freely as those on a warmer aspect, or make quite so good growth, but they would cover the house sooner than anything else. For the fence, *Cotoneaster microphylla* and *C. Leelanil* will do admirably. *Azara microphylla* is a good hardy climber with rather a neat habit of growth.—J. C. C.

— Vello's Virgilian Creeper (*Ampelopsis Veitchii*) is the best creeper for a north aspect. Green and Variegated types will do, as would also *Pyracantha* and *Cotoneaster Simonsi*. The *Cotoneasters* and *Pyracantha* would do on the wood-paling.—E. H.

5423.—**Everlasting Peas.**—I do not think you are likely to get much satisfaction out of Everlasting Peas the first year after sowing. They may blossom late in the summer, but not before. Your best plan appears to be to sow the annual Sweet Peas at once to cover the fence for this year, which they will quickly do and be attractive all the summer. At the same time you may sow the seed of the Everlasting Peas in the greenhouse and plant them out 1 foot apart in good ground, and early next spring you can plant them where they are to remain with the certainty that they will flower the same season.—J. C. C.

— Sow the seeds in pots in the greenhouse; but under any circumstances they will hardly get strong enough to cover a bare falling next year.—E. H.

5445.—Plants for a narrow border.

—Why not set out hardy border plants? These give little trouble after they are once established, and are not only interesting, but useful for supplying cut flowers. For instance, *Alyosotis*, Primroses, Wallflowers, *Aubrietia purpurea*, and *Silene compacta* could be grown from seed. These would make a nice display annually. If an edging is wanted of a low-growing nature *Sedum glaucum* would answer well. The glaucous tint of its foliage would correspond well with the dark-green Ivy at the back. The following are all low-growing, easy of cultivation, and very showy: *Lychnis viscaria* fl. pl., *Stematis speciosa*, *Prigeron aurantiacum*, *Helenium pumilum*, *Narcissi* of sorts, *Alyssum saxatile*, *Anemone apennina*, *Saxifragas* of sorts, *Hepaticas*, *Arabis albiloba*, *Crocus*, *Snowdrops*, *Campanula trachelium*, *C. muralis alba*, *Chrysanthemum maximum*, *Christus Rosa*, *Lavender*, *Rudbeckia purpurea*, *Zauschneria californica*, *Veronica prostrata*, and *Solomon's Seal*.—S. P.

5296.—**Lycimachia Nummularia aurea.**—I doubt very much if seed of this is obtainable. I have referred to one of the most extensive lists of hardy flower seeds, but it is not offered, nor is it worth the trouble required and time lost in waiting to raise it in that way. Almost any nurseryman who deals in hardy plants would supply one of this for a few pence, and planted and tended under suitable conditions it might soon be increased to any extent.—A. H.

5376.—Climbing flowering plants.

—Almost any of the usual run of hardy climbers will thrive here, though they may not flower quite so early or profusely as on a south aspect. A few good ones would be *Roses* (I have a splendid *Gloire de Dijon* on a north-west wall that flowers abundantly during the summer), *Clematis* of sorts, *White and Yellow Jasmines*, *Passion-flowers*, *Honeysuckles*, *Wistaria*, &c. *Tropaeolum speciosum* would thrive admirably also.—B. C. R.

— I should say the best of all flowering plants to grow up by the side of a house window in a west aspect is a *Gloire de Dijon Rose*, as it blooms both early and late, and if you want two plants for the Red Glory (*Reine Marie Henriette*) is a suitable companion to the other. Black or Indian Corn that had been washed

climbing plants. The White Jasmine may be mentioned as one of them. Then there is the Honeysuckle, *Pyrus japonica*, Forsythia suspensa, Fiery Thorn (*Crataegus Pyracantha*), which is evergreen, and bearing clusters of coral red berries all the winter.—J. C. C.

5373.—**Moss on a tennis-lawn.**—You will never get rid of the Moss all the time the soil remains in its present impoverished condition, as is indicated by the presence of the Moss. Have as much of the Moss raked off as you can at once, and immediately after give the lawn a good dressing—sufficient to nearly hide the Grass—of rich soil, or preferably short rotten manure. Repeat the application again next April, and twice each winter following until the Moss disappears, which it is sure to do as the Grass gets strong enough to overpower it. Now, owing to the poorness of the soil, the Moss overcomes the Grass.—J. C. C.

5383.—**Good blue annuals.**—*Nemophila insignis* (pale-blue, height 6 inches), *N. atrococcinea* (dark-blue, 4 inches), *Placelia campbelliana* (intense cobalt-blue, 1 foot), *Whitlavia urandiflora*, and *W. gloxinioidea* (violet-blue, about 1 foot), and *Brachycome iberidifolia* (blue, 9 inches), you will find some of the best annuals of this colour. If you want anything taller for the back, the blue annual Larkspurs will do nicely. *Linnæa sibiricum* is also a rather pretty thing. I have never heard of, much less seen, a white *Nasturtium* yet, but the pale-coloured varieties are not equal to the dark as bloomers. Lastly, do you think blue flowers will go well with Roses? I do not.—B. C. R.

5413.—**Birds eating Crocuses.**—Have you tried a few lines of blue cotton run along each row just above the flowers? If done neatly this does not look at all bad, and I have never known Crocuses, Peas, or anything else touched where this was done.—B. C. R.

—Birds are great enemies to the Yellow Crocuses, and there is no way of keeping them off except by shooting them (a harsh measure), or the remedy you have adopted, but which is, unfortunately, unsightly. It is interesting to note—in London gardens in particular—how the mischievous sparrows will invariably "go" for the yellow lines of Crocuses and pick off the petals, leaving a golden litter on the Grass edge.—C. T.

—Is the "Narice" who asks about this sure that the birds eat the Crocus flowers, or do they only pull them to pieces? The eating is curable, but the malicious and depraved habit which town sparrows have of pulling flowers to pieces, about which all kinds of suggestions have been made from time to time, seems incurable. With me, in the country, pheasants are the principal offenders and they eat Crocus flowers whole, as fool, also Scarlet Anemones, Dog's-tooth Violets, Fritillaries, and other flowers. By making a strong infusion of Quassia-chips, boiling two or three ounces in a gallon of water, and watering in dry weather just before the flowers begin, I prevent it, but it must not be deferred till the birds' appetites have been whetted by finding some of the flowers palatable.—C. W. D.

5412.—**Hops on a wall.**—Where neatness is considered the old stems are cut down in autumn when the leaves die. There should be something permanent to support the shoots during growth. Wires or strings stretched tight will do.—E. H.

5349.—**Best Lilies.**—A few weeks ago I gave the names of a few of the best Lilies, and you should refer to that list. Lilies should be planted at once if not already done, and in good peaty soil. It is peat soil they like, as a rule, and are never happier than in such a place as a Rhododendron-bed, where they are protected when growing in the spring, and the bold spikes of flowers are set off by the foundation, so to say, of rich, green leafage. There is no great number of White Lilies, the pure-white one being the beautiful white *Madonna Lily* (*L. candidum*), which you know well, as it is the most common of all. This is rather quixotic in its behaviour, and the finest mass of it I have ever seen was at Bath, on a warm slope in full exposure to the sun, the soil loamy; and one often sees splendid clumps of it in cottage gardens. Another very beautiful White Lily is the *L. speciosum* or *L. laucifolium* or *alium*, or *Krietzleri*, which is pure-white, and blooms in the autumn freely. A large bed of this was a feature of great interest last year at Kew, and lasted a considerable time in beauty, the pure-white flowers being welcome late in the year. It is also serviceable for pots. *L. auratum virginicum*, a variety of that well-known species, is nearly

white. But my selection would be the two first mentioned, which are really white. As regards other kinds, select *L. elegans* in variety, the fine old Orange Lily, *L. croceum*, *L. auratum* and its many varieties, which bloom in August, the tall-growing and strikingly handsome *L. pardalinum*, the stately and deep-coloured *L. superbum*, the Tiger Lilies, especially the variety named *splendens*, a glorious flower for colour, and forms of *L. speciosum*, into the flowers of which crimson largely enters, and the white variety already mentioned.—C. T.

THE SEA LYME GRASS (ELYMUS ARENARIUS).

THIS British maritime Grass is well worthy of garden cultivation. It is a valuable plant for clothing a bank of loose soil or even sand, as its roots run through, forming a perfect mat, and effectually holding in position the soil of the bank. It is very hardy, and makes an excellent covert plant. If planted in deep good soil upon the shrubby margin it grows more vigorously, attaining then to 4 feet in height. Its sole beauty is its leaves, which are very effective in appearance, being of a glaucous or blue-green colour, and as the flowers are not very showy they might be removed to preserve the plant in its beauty of leafage for as long a time as possible. It is easily increased by division, and rapidly grows into a large specimen. In a wild state it is most abundant upon our northern shores. There is also an American representative of this family, *E. condensatus*, which is very ornamental and must be included in a selection of the best Grasses. It is very vigorous, of tufted habit, dense and erect, grow-

THE KITCHEN GARDEN.

SPINACH AND ITS CULTURE.

THE first sowing for summer use should be made early in March, as a rule; but in warm soils and situations a small sowing may be made in February.

SUMMER SPINACH.—Owing to the Summer Spinach being so liable to run to seed, it is advisable to make small sowings often rather than to make large sowings at long intervals, as by the former plan a regular supply of fine young leaves is ensured, whereas in the latter case small, tough leaves have often to be used in consequence of successional crops not being sufficiently advanced to give a supply. It is therefore obvious that a sowing should be made once a fortnight, or at longest every three weeks, during the summer months. These sowings may consist of the Round Spinach for the first two or three sowings, and the Flouders or the Lettuce-leaved varieties for sowing through the summer. These two last-named kinds are far superior, both in quality and cropping, to the Round Spinach. For summer sowings it is best to choose as shady and moist a situation as possible to ensure watering, as well as to prevent the plants from running to seed too quickly. All Spinach-seed is benefited by being sown in water for a few hours previous to sowing, inasmuch as it germinates more quickly and the growth is often stronger. Sowing in drills is by far the best mode of sowing the seed, as then the crop is more easily kept free from weeds, and watering or mulching can be effectually done, when desired as well as rendering it much easier to gather the crop. The drills

OUR READERS' ILLUSTRATIONS: THE SEA LYME GRASS (*Elymus arenarius*). Engraved for GARDENING ILLUSTRATED from a photograph sent by Mrs. MARTIN, Bournbrook Hall, Birmingham.

ing to a height of 8 feet. The leaves are long, arching, and graceful, and the shoots are terminated by a flower-spike 6 inches long and greatly resembling an ear of Wheat. B.

5351.—**Ashes for the garden.**—These are very useful in the garden, but not of much use for mixing with the soil, unless it is very stiff, when it will help to make it work better; they are excellent for making walks, for covering the bottom of cold frames, and for placing over the crown of half hardy plants in winter—in the latter case I can never get enough ashes to use.—G. G. H.

should be about 1 foot apart, and the plants after thinning at least 6 inches asunder. The Lettuce-leaved and Flouders require even more room than this, if the production of fine large leaves be aimed at. The last summer crop should be sown on a well-prepared border or quarter about the middle of July, in drills about 18 inches apart; this will yield a good supply of fine large leaves till October is out.

FOR THE LATE OR WINTER CROP prepare about the end of July a border or sheltered quarter. Apply a good coating of thoroughly decayed manure, trench the ground well, and cast it up in the shape of a level surface as great a surface as possible to the influence of the atmosphere. URBANA-CHAMPAIGN

Every dry day till August 10th or 12th cast down the ridges and pulverise with a steel fork, so as to sweeten and incorporate all together. Then draw lines 1 foot apart and sow the hardy Prickly variety. As the plants advance thin them out from 6 inches to 9 inches apart, and maintain a healthy and vigorous growth by constant surface stirrings in suitable weather. This, if attended to, prevents canker, and encourages the production of an abundance of fine leaves for use every day throughout the winter. Timely fore-thought should be taken to shelter a portion with a row of short stakes about 18 inches high, interwoven with Fern, straw, evergreen branches, Furze, Heath, or other material, which should be neatly applied, and also made wind-proof. Thatched hurdles or frames, closely made, of battens hooked together and thatched, might also be used for the purpose of protecting from frost.

THE BEST SEASON, to supply leaves in the spring, generally consists of the Prickly variety. The time to sow this crop, however, depends upon the locality. If sown too soon it runs to seed the same season and is useless. To sow it late enough to have a crop of leaves without the plants throwing up their flowering stems is what has to be aimed at, and for this reason many sow twice for the winter crops. In some parts of Scotland and the North of England the middle of August is not too soon, while in the south it is not often safe to sow before the end of September; but a practical acquaintance with the climate and locality will generally be the best guide. This crop is often sown after Potatoes or Onions. The winter crop will generally afford a good supply of leaves till nearly the beginning of June, by which time the Round or Summer Spinach will be coming in its abundance. A deep, rich, moist soil is necessary to grow good Spinach, and if liberal supplies of liquid-manure be given to summer crops a great advantage will be gained thereby. Some care is required in picking Spinach, especially in winter, when the growth is often not equal to the demand. Indiscriminate picking will soon ruin the crop; the largest leaves should therefore be taken first and picked off singly, so as to avoid injuring the plants.

CULTURE FOR MARKET.—English market gardeners seldom grow Spinach as a summer crop, as it "bites" or runs to seed before many leaves have been gathered from it, and in that case it is by no means a profitable crop. The Round-leaved sort is that which is used for spring sowing, the first of which is made in February, a second about the first of March, and another sowing or two at an interval of three weeks or thereabouts, just as space and convenience permit. The latest spring sowings are made in a damp, cool piece of ground, provided such can be obtained, as, thus circumstanced, better leaves are produced in hot weather than in dry and warm soils. In July, if the weather be moist, a sowing of the Round-leaved variety is usually made on a spare piece of ground for autumn use. Early in August a large sowing of the Prickly-seeded or the Flemish is made broadcast on fields or in rows about 8 inches apart. Some growers prefer the Flemish on account of its large fleshy leaves and hardy constitution, and it sells in the market better than the Prickly sort. By sowing in the first and last week of August and the middle of September a succession of Spinach from October till May is easily kept up. Coleworts are frequently planted in a field of late Spinach, at 3 feet or 4 feet apart. In damp winters a large proportion of the roots may die, but in ordinary winters they survive, and produce an abundance of large fleshy leaves in spring. No care is taken with this crop from the time of sowing till gathering, beyond hoeing and thinning once or twice. Spaces under fruit-trees are also covered with Spinach sown broadcast, and as the trees are not furnished with leaves they do not shade the plants. Open fields are also often sown with Spinach in beds, which are covered by throwing soil over them from the alleys. Dig the beds in autumn and also planted at the usual distances apart.

the time the Spinach has come well up the Cauliflowers will have become well established, so that the Spinach, which as soon as ready is removed for market, does not injure the Cauliflowers. The Giant Virolloy Spinach (here figured) is an excellent kind, and requires rich ground.

5449.—Growing Peas.—The best way to set about growing Peas in such a soil is to mark out the rows fully 6 feet apart—wider, if possible—and crop the ground between with Potatoes or any similar crops. The advantage of giving so much space between the rows is that

Spinach "Giant Virolloy."

the Pea-plant derives to its best by the full exposure of its leaves to sun and air. When but 3 feet or so of space is allowed between the rows the plant grows weakly, and, consequently, the crop is a thin one. If possible let the rows run north and south; both sides then obtain an equal share of light. Dig out a trench 1 foot wide and 15 inches deep, as though for Celery. Break up the bottom of the trench at least 4 inches deep to allow surplus water to pass away quickly during heavy rains. Place at the bottom of the trench a 6-inch thickness of partly decayed farm-yard manure. On the manure lay 4 inches of soil—not that from the bottom of the trench, if it is heavy and retentive—scattering along with it quicklime—say, a good handful to every 2-feet run. Mix the lime with the soil, and on the top of this sow the Peas in a row 6 inches wide. Some persons sow the seed quite thick in a narrow space of, say, a couple of inches. The consequence is the plants are so close together that they rob each other of light, but when spread over the space named they grow more sturdily, and bear a better crop. One pint of seed is sufficient for a row 40 feet long. Before sowing the Peas place them amongst red-brick for a time, so that they are quite covered with it. Add 2 more inches of soil, sprinkling a little more lime along with it, and I think you will have success. When the Peas are 4 inches high earth them up, and place the stakes alongside them at once. If the weather threatens to be hot and dry, mulch the surface 1 foot wide at each side of the row to prevent the evaporation of moisture. Do not scruple to give abundance of water during a prolonged drought.—S. P.

—Yes, lime is what is wanted. Give the ground a heavy dressing of once, but let it lie for a fortnight and then dig it in. A little superphosphate hoed in (and sprinkled on the surface) when sowing will also help you. Do not put any more manure on the ground for the present.—H. C. R.

5447.—Growing Tomatoes.—The long box will be better than 10-inch pots for Tomatoes, as the plants will not suffer so much for the want of root-moisture in the box. You may with advantage increase the width of the latter another 3 inches. It is desirable to cut holes in the bottom of the box; these may be 2 inches over and 1 foot apart. If yours is a cold greenhouse it is no use to sow the seed until the beginning of March, nor is it desirable to have many sorts. Blenheim Orange is a good yellow variety, and Conference or Hackwood Park are free-setting red sorts when grown under glass, and both produce large, handsome fruit.—J. C. C.

—Yes, your plan will answer capitally, and be far better than growing the plants in pots. Unless the box is made roughly—the bottom not fitting the sides too closely—it will be necessary to bore holes in the bottom for drainage—say, two together a foot apart. It will be useless to sow seed in a cold house until the middle or end of April, and by that time the plants ought to go in, so that it would be much better to buy these.—R. C. R.

5438.—Tomatoes for market.—I do not find in practice that there is much difference in the bearing capacity of what are generally known as the Perfection type of Tomatoes. Halloway's Excelsior is a good one, and so is Hackwood Park if you get it true. Large Red is not suitable for indoor culture in summer, the fruit being too corrugated. It is, however, a good bearer. I devote a small house every year to Hackwood Park, and intend to continue to do so, as having tried Ham Green Farouito and a lot of so-called improvements I do not find them to be my better, if so good.—J. C. C.

—Hackwood Park is a very productive and excellent market variety, the bushes being large, but its weak points are colour and quality. A good strain of the Large Red is also much grown for market, as though the fruit is rather rough it sets well and crops abundantly. But the Tomato of the future is High Gem, of which fruit is now realising 3d. per pound more than that of any other variety. The plant is also extremely dwarf, and sets as well as the Large Red.—E. C. R.

5425.—Sowing Peas.—If Peas are sown in pots, they require plenty of light and air, and should not in any way be placed where the plants would be drawn up weakly. They should be planted out when the plants have grown to the height of 3 inches or 4 inches, but must first be well rooted to the open air. A cellar would be about the nearest place to put the pots containing the seed. It would be much better to sowing in the open garden at once. The first week in February is a very good time to sow early Peas. When sown at that time they are sometimes ready to gather as soon as those sown in November, and the February sowing usually gives the best crop. Try some both ways—sowing in pots to begin with, and sowing in the open garden at once. You will find the pot system plenty of bother with little result.—J. D. E.

—Better sow the Peas outside now. There will be nothing gained by sowing in a cellar, and not much in an unshaded room. They will come quite as early if sown on a man, sunny border, and the crop will be better, and will give less trouble.—E. H.

5374.—Tomatoes under glass for market.—The best Tomato for growing for market, or for any other purpose, is undoubtedly the new variety raised by Mr. B. C. Ravenscroft, of High, Crawley, named "High Gem." It excels in shortness of growth, boldly showing the first truss about six inches from the soil (when properly grown), and the trusses rarely exceed that distance apart up the stem, hence it is a genuine cropper. The fruit is of suitable size for market, and being solid is, therefore, a good traveller. The colour and flavour are simply perfect.—P. F. Le SERRE, Jersey.

5370.—Making a Tomato-house.—My experience of Tomato growing leads to the conviction that the larger the houses the better, for the simple reason that large houses cost less to build in proportion to small ones. At the same time, for early work small houses are very useful. I consider for Tomato growing the house cannot be too large nor yet too small, as good fruits have been grown in a garden-frame. Make the Tomato-house as high and as wide as the lights will run to.—E. H.

5359.—Tomatoes in boxes.—Ordinary sugar-boxes, which are about 2 feet long, 18 inches deep, and 15 inches or 16 inches wide, do capitally for Tomatoes, two plants being placed in each; but as they are usually opened on the narrow side it is a good plan to nail this up again and take off a wide one, so that they may stand on the flat, as Tomatoes do not require a great depth of soil. Egg-boxes are also very suitable, two plants being placed in each division, or half, or four in an entire 4-foot box.—B. C. R.

5407.—Late Potato.—After trying a great many varieties, I find Reading Giant the most profitable to grow. It is an enormous cropper on almost any kind of soil, a capital keeper, and of excellent quality. Some of the tubers were very large, but the bulk of them are of medium size.—H. C. R.

—Winchester Castle is perhaps the latest Potato in existence, although White Beauty of Hebron is remarkably good just now, especially when grown in light loam soil. The former is pointed-shaped, and not too large. The flavour is good, while the cropping quality leaves little to be desired.—S. P.

5443.—Potatoes for show.—I consider the best variety for show is Schoolmaster. Nothing can beat it when well grown and selected. The best Kilmy for early shows is the Earl of Argyll, but for late shows I would recommend Reading Giant.—W. Henry Dunfries.

FRUIT.

5384.—Pruning Vines.—I would advise "Kent" to get some experienced gardener in his locality to look at his Black Hambro' Vines before proceeding to the very radical remedy of cutting the old spurs that are 1 foot long right off. If I did such a thing, I should certainly not expect any Grapes during the current year, and I should think myself very fortunate if the old spurs sent out any shoots from the base at all, for the wood will be as hard as iron; a far better remedy is to grow young rods up between the old ones, and then cut the old ones right away, either all at once, or partially. I prefer the gradual replacing of the old rods with new ones, by cutting off all the spurs from the base of the old rod to make room for the new one, and the following year cut the old rods out altogether, so that there need be no total loss of crop, and the bottom of the Vine will be as heavily cropped as the top—in fact, no greater bluish can be seen in vinerias than an uneven crop. The bunches should be equal all over.—J. C. H.

5363.—Rooting cuttings of fruit-trees.—There are a few Apples that may be propagated by cuttings, but they are not of much consequence, and it is far better to obtain the trees from a nurseryman who understands his business and who produces his young fruit-trees by grafting them upon suitable stocks in the spring, or by budding them in the late summer or autumn months. There is no harm in trying to strike cuttings. Put them in some time in November in the open garden. Strong young wood should be taken off with heels.—J. D. E.

PEAR TREES FOR SMALL GARDENS.

The accompanying woodcut represents the simplest and best form of tree for rapidly covering walls with Pears, and one especially well adapted for small gardens. Before this and like forms, the old horizontal pattern, which takes so many years to form, should give way. Among the many advantages that belong to the upright form may be mentioned that of simple training. To establish such trees, all that need be done is to take a young tree or seven-branched tree, and place the branches as near

Upright trained Pear-tree for a small garden.

as may be in the desired position to ascend. It is not even necessary to have the branches opposite, as without that the wall may be perfectly covered. With trees of this kind planted close enough together, a very few years' growth will suffice to cover a wall that would not be covered for a great length of time by the old method of training. B.

5427.—Peach dropping its buds. If all Peaches had the constitution of George there would be no bud-dropping. The

causes of bud-dropping are various. Unripe wood, dryness at the root, too much overhead, a severe attack of red-spider during the previous summer are some of the most common causes of bud-dropping. There are some kinds which always drop more or less of their buds, but under fairly favourable conditions enough blossoms remain for a crop.—E. H.

5423.—Management of a vinery.—The house should be started not later than the middle of January to cut ripe Grapes the end of June, and even then only the early varieties will be ripe, and no time must be lost. You will have to start with a night temperature of 50 degs., allowing 10 degs. to 15 degs. rise in the day from sun heat before ventilating. Chase early by 2.30 till middle of March, saturating the atmosphere by using the syringe freely. As soon as the buds break raise the night temperature to 55 degs., and the day temperature in proportion. When the foliage expands raise the night temperature to 60 degs., and when the Vines are in flower the night temperature may be advanced to 60 degs., beyond which it need not go. As the season advances more ventilation will be required, a little air being admitted early in the morning to let out the impurities accumulated during the night. The syringe need not be used after the berries are thinned, as sufficient humidity can be secured by damping paths and borders. It is impossible to say all that is necessary to be said upon forcing early Grapes in a short newspaper article, but a regular reader will find many hints on Grape growing as the spring advances. To get rid of the woodlice place a few toads in the house, and lay a few pots about with a slice or two of Potato or Carrot hidden away beneath a wisp of dry hay, and examine the traps frequently and kill the insects.—E. H.

To cut Grapes in June, the vinery should be started about Christmas, with a very moderate temperature—at first, say 48 degs., raising it to 50 degs. as a minimum after the second week, and when the shoots have grown a few inches, to 55 degs. By the time the Vines are in flower, the minimum should be 65 degs. The same treatment should be given if the house is started at once, but the temperature may be more rapidly raised now than earlier in the year. Woodlice have increased because of the fogs giving a dry heat. Wrap a boiled Potato in hay, and put it with the hay into a flower-pot; lay it on its side, and this will be found an excellent trap.—J. D. E.

5435.—Iron fencing.—Hardy fruits, such as Plums, Apples, Pears, and Cherries will do trained to the iron fence, but not Peaches or Apricots; the position will be too cool and draughty. They want a warm wall. The fruits likely to succeed best are Pears and Apples. These might be planted without fear.—E. H.

By all means plant the fruit-trees as suggested. There is no objection whatever. All that is necessary is to put a bit of cloth between the iron and the shoot beneath every tie.—B. C. R.

CHRYSANTHEMUMS.

5437.—Pompon Chrysanthemums.—"Heron" means early-flowering varieties of Pompons, not those generally recognised as Pompons that flower under glass in November. The early-flowering section are a somewhat new type, and owing to the early season that they flower in are suitable for beds out-of-doors, and for this reason must not be associated with the ordinary November kinds, of which Mme. Klise Dorlan or Mme. Marthe are types. The following twelve varieties all belong to the early-flowering section such as "Heron" requires, and possess much range of colouring. I append the colours of each, that a selection suitable for any person can be made from this number. La Petite Marie (white, very dwarf, useful for edgings to beds or borders), Little Bah (crimson-brown, flowers small), Mme. Picoul, light rose-purple, Nanum (creamy-white, early), Mignon (sleep golden-yellow, good border), Frederick Pele (crimson, tipped gold), Alice Butcher (orange-red), Anastasia (light purple, dwarf), Felberta (bright canary-yellow), Flora (golden-yellow), Lyon (rosy-purple), Piorey's Seedling (orange-bronze), St. Crouts (light-pink), Salomon (rosy-pink, very free, dwarf habit).—E. MOLYNEUX.

Mme. Desgrange is not a Pompon at all, but an early-flowering Japanese variety. What you want are such as Heron, Yellow Snowdrop, Mme. E. Dordans, La Petite Marie, Marlon, Rosinante, Mme. Marthe, Golden Maid, Marthe, Victorie, &c.—B. C. R.

FERNS.

A GOOD HARDY FERN FOR THE GARDEN OR WINDOW.

ASPIDIUM ACULEATUM.

Of this, one of the hardiest and most effective of all our native Ferns, numerous forms occur in various parts of the world. Benthams says it is found from the Mediterranean to Scamliaria, extending eastward into Central Asia; in North and South America, and generally in the

Prichly Shield Fern (*Aspidium aculeatum*.)

Southern Hemisphere. Our illustration shows the elegance of the plant, and, if grown in a shaded situation, it retains its fronds nearly all the winter. In deep, rich soils its handsome, dark-green fronds attain a height of from 2 feet to 3 feet, and wherever moist soils in the wild or rock gardens have to be furnished, this plant is well worth a place. It also forms one of the very best of all hardy Ferns for pot-culture in rooms or windows, retaining its stout old fronds until the young ones shoot up in the spring, and only requiring to be sprinkled or syringed over now and then in order to remove dust and other impurities. B.

5416.—Maiden-hair Ferns and Selaginellas.—The first named are easily raised from spores, which if fresh germinate freely in a genial temperature, but with only a cool-house the best plan will be to purchase young plants. These can often be obtained in boxes containing a hundred or so for about five shillings, or if in smaller pots the price rises about three shillings per dozen. Selaginellas are so easily increased by means of division or cuttings in a moist warmth that any quantity may be obtained in a short time from a few old plants. But in order to propagate such things successfully you should have a small frame or glass-covered box fixed in the warmest corner of the house over hot-water pipes or the flue, if there is one, or else one of the handy little propagators now so cheap.—B. C. R.

The best way would be to buy small plants, as you find considerable trouble in the other matter under the circumstances. You may get a good collection of the more popular Aiantams and Selaginellas at a very reasonable rate. Here are a few of the best Maiden-hair Ferns: Aiantum cuneatum (the best of all, and largely grown to give fronds for cutting), A. Paotii, A. pedatum, A. Regine, A. rhodophyllum, A. tenerum, and A. Victorie. The most free-growing of the Selaginellas is S. Kraussiana and its variety anrea, which is of quite a golden colour; it is a lovely kind for pots.—V. C.

5452.—Adiantum Capillus-veneris.—In a cool greenhouse this is grand. I find a compost of peat, loam, and leaf-soil in equal proportions, with a dash of coarse sand, suit it very well. It does not look so well in pots as when growing in a greenhouse well, where, if syringed frequently, it soon makes a pretty feature. Plenty of drainage (pieces of wood) in the bottom of such soil will ensure success.—E. C.

INDOOR PLANTS.

5353. — **Aspidistras in pots.** — As the potting is so full of root, and the new leaves are not so large as they should be, these Parlour Palms should be divided and repotted; but not until the end of March, unless they can be placed in a warm greenhouse after this operation. Any ordinary compost, such as loam, with a little leaf-mould, soot, and sand, will suit them, and the pots should be well drained, covering the hole with a piece of crock with the concave side downwards, and arranging several pieces round it, so as to keep the way clear for escaping water. These crocks should be covered with a bit of dry Moss, and receive a dusting of soot, which both prevents the ingress of insects and helps to nourish the plant. The mass of roots being turned out of the pot, should be carefully divided with as little injury as possible. Each plant will make two or three specimens, in 6-inch or 7-inch pots; these can be given a shift in another year when they have filled the pots with roots. After repotting give one good watering, but do not repeat until the surface-soil be dry; over-watering before the roots are settled is apt to rot them, and so do more harm than good. The Aspidistras should be given all possible warmth after being repotted. — J. L. R.

5340. — **Treatment of Chinese Primulas.** — The date for sowing the seed must be regulated by the time you require the plants to bloom. For plants to flower from October onwards through the winter, the seed should be sown in March, potting the plants off into single pots in April, and shifting into their flowering pots in June. A mild frame is the best summer quarters, setting the pots in coal-ashes. The first bloom-spikes should be pinched out, after which they will send up several large trusses of flowers. For ordinary decoration 4-inch and 5-inch pots are the most useful, but a few of the finest, shifted into 7-inch pots, will make fine plants for vases. — J. G. H.

5347. — **Early Lily of the Valley.** — "T. Harrie" can scarcely expect to get Lily of the Valley to flower very early if he has only the convenience of a frame, for hardly any cultivated flower needs a higher temperature than Lily of the Valley to get them to flower far in advance of their natural season. A bottom-heat of 80 degs, and top-heat of 65 degs, are absolutely necessary to get these popular flowers in bloom in mid-winter; but with a frame they may be had in bloom about March, and ought to be potted up at Christmas, and plunged in a gentle bottom-heat, trusting to the increasing solar heat to bring them into flower in March. — J. C. C.

5400. — **Lamp for a propagator.** — The size of the lamp, and whether it should be a duplex or single burner, depends entirely upon the size of the propagator. The one to which I referred in the communication alluded to by "G. T. M." is heated by a lamp 8 inches high with a single half-inch wick. The size of the lamp should in every case be in proportion to the size of the box above it. If it is too large the heat would be too great, besides increasing the cost by burning the oil to waste. The whole construction and management of a propagator is very simple when the lamp is of the right size, and the tray only half filled with water. — J. C. C.

5430. — **Setting a coil boiler.** — The proper way to do this is to build the coil into a circular furnace, with a space of about 2 inches between the outside of coil and inside of brick-work. Do not let the last turn of coil cross the exit into chimney, or it will burn through very quickly. To connect the ends of coil and pipes make a rough collar of leather or board to fit on each, push it in about 4 inches, pack well with old rope or yarn, and, lastly, put in about 2 inches of fresh Portland cement, made rather stiff, and some lumps of brick forced in the cement. This will be as tight as wax and last a lifetime. — B. C. R.

5439. — **Removing hot-water pipes.** — I do not think the rings will be much use again, as they soon get set and harden under the influence of heat. You may try, but if you have the least trouble with them I should advise you to discard them altogether, and make the joints first with a packing of rope yarn, and then with

corn in pieces and twisted up, and then with about 1 1/2 inches of fresh Portland cement, mixed with water to a smooth paste, and worked well into the joint all round, and smoothed off. This sets like a rock, never leaks a drop, lasts a lifetime, but is easily cut out with a sharp chisel, if necessary. — B. C. R.

5431. — **Unhealthy Fuchsias.** — "New Beginner" has perhaps got red-spider or thrips on his Fuchsias. From his signature, it may be he does not recognise these pests. I would advise him to show a leaf or two to a friend who is further advanced in floriculture. A temperature of 50 degs is scarcely high enough for growing Fuchsias. Ten degs. higher would be better, and an occasional syringing would be a check to insects. The real cause cannot be assigned, with any certainty, from the description given. — P. U.

GOOD BERRIED PLANTS. RIVINA LEVIS.

The brilliant scarlet berries of this plant render it, when well grown, one of the prettiest ornaments for the hot-house, conservatory, or even a warm room. It is quite easily managed, stays seeds if it even growing where they fall, making handsome specimens. For indoor decoration few subjects are more interesting, and a few plants may be so managed as to have them in fruit in succession all the year round. Any kind of soil will answer for this Rivina. Cuttings of it strike freely, but it is easiest obtained from seed. Either one plant or three may occupy a 6-inch pot; that is the best size for table decoration. Usually it is best to raise a few

Berried shoot of Rivina levis.

plants every year, and then discard the old stock; but some may be retained for growing into large specimens. These should be cut back before they are started into growth. The berries yield a fine but fugitive red colour. Miller says that he made experiments with the juice for coloring flowers, and succeeded extremely well, thus the Tuberosa and the Double White Narcissus variegated in one night. Of this species there is a variety with yellow berries which are not quite so handsome as the red, though very attractive. R. humilis differs from levis in having hairy leaves, those of levis being quite smooth. It also differs in the duller red colour of the berries, levis being much the prettier. Both are natives of the West Indies. R. B.

5442. — **A propagator.** — No, the seeds are not sown in the Cocoa-nut-fibre, but in pots or boxes of prepared soil. In some cases a much greater depth of Cocoa-nut-fibre is used than I find necessary, as the greater the depth this is the more heat is wanted to obtain a top-heat equal to the bottom. You have read the other part of the instructions right. An inch between the top of the lamp and the zinc tray is quite enough for the size of the propagator given, and a lamp with a half-inch wick is large enough. — J. C. C.

5426. — **Cuttings of indoor plants.** — Take the cuttings any time during spring, when healthy young shoots can be obtained; and when there is a brisk bottom-heat available Poinsettias can be struck up to the end of May or even later, and still make good flowering stuff. Linnæa is a hardy plant. Perhaps Linnæa is the best Indian species, in bloom? — E. H.

RULES FOR CORRESPONDENTS

Questions. — Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southwark-street, Covent-garden, London. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by abstaining, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, rules, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number of which they appeared.

5438. — **Gun licence.** — Does a person require to take out a gun licence for shooting or a spring bird in a garden? — T. G.

5408. — **Propagating Gum Cistus.** — I should be glad to know of the best way in which to propagate Gum Cistus? — M.

5470. — **Destroying moles.** — Will anyone kindly tell me how to do this? My garden has been taken off a field and has many moles in it. — M. T. C.

5471. — **Shrubs under trees.** — I shall be much obliged if someone will inform me what are the best shrubs to plant under Horse-chestnut and Lime-trees? — K. K. B.

5472. — **Bulphuric acid and weeds.** — Will anyone tell me the proportion of sulphuric acid I should use to water for destroying weeds on a carriage-drive? — J. T. Guteshew-on-Tyne.

5473. — **Plants for a north greenhouse.** — Will someone kindly give me the names of a dozen plants suitable for a greenhouse (slightly heated) on the north side of the house? — T. S.

5474. — **Best Pea for market.** — Will someone kindly inform me which is the best pea to grow for market without sticks, and how should they be sown to be most profitable? — A. HERRICK.

5475. — **Blight on Beech-trees.** — Will anyone kindly tell me whether this disease eventually kills the trees? Also whether there is any practical treatment for it in the case of tall-grown trees? — FARRIS.

5470. — **Bulding plants.** — I should like to know of a good substitute for both the yellow and dark Calceolarias for bedding, and also the names of a few good winter hardy plants for carpet-bedding? — LINDSAY.

5477. — **Tree Carnations from seed.** — Will someone kindly tell me if Tree-Carnations raised from seed this spring are taken up in the autumn and put under glass will they bloom in winter? — A. READER.

5478. — **Wormcasts.** — Are wormcasts of any use as soil or as manure? I get a good barrowful from one rolling of my lawn in damp weather. They stick to the roller and are then scraped off. — A. H. C.

5479. — **Blood as manure for Vines.** — I have heard that blood is a good manure for Vines. Will someone kindly state if such is the case? Also what it should be applied, and in what quantity? — AMATEUR.

5480. — **Grafting an Aralia.** — Will someone kindly give me instructions how to graft an Aralia eleagnifolia? It has got very tall and bare at the bottom. Would Aralia Sibirica do for the stock to graft on? — HORTUS.

5481. — **Seeds of Castor-oil plant.** — Has long a few seeds of this plant, I should be glad if anyone will give me some advice as to soil, time of sowing, &c., and if heat is required to make the seeds germinate? — BOBAY.

5482. — **Fern compost.** — I should be glad if "J. J." or any other reader, would be good enough to give me instructions as to the making of a good general compost suitable for Ferns, Adiantum, and other Ferns? — READER, Plymouth.

5483. — **Spring sown Onions.** — Will someone kindly inform me something as to the culture of spring-sown Onions on light, sandy land? Good south aspect. My Onions always have grub. Will a quantity of soot be beneficial? — W.

5484. — **Planting Dahlias.** — I have some good Dahlia roots and want to get them in flower as early as I possibly can for sale. What is the very earliest that I may plant them in? I have no frame or greenhouse. — EXETERIAN, Wotton-in-Notze.

5485. — **Best Dahlias.** — I should be much obliged if someone would kindly give me the names of the best varieties of Dahlias, say 24 each of Show, Fancy, and Cactus. Also the title and publisher of the best work on the culture of Dahlias? — ROSE HILL.

5486. — **Cardinal Willows.** — I see in GARDENING, Jan. 27th, page 674, the Cardinal Willows are highly spoken of. Will "S. H." or someone else, kindly let me know (1) how far they should be planted apart? (2) Where can I get them from? — S. T. FISHER.

5487. — **Artificial manure for Vines, &c.** — Will someone kindly tell me what is the best artificial manure to apply to Vines (Linnæa) manure not being easily obtainable? Also for small fruit-trees, Citruses, &c., and Seakale? Nalire Guano has been suggested. — T. S.

5488. — **Arum Lilies.** — Would some grower kindly tell me if the miniature variety "Little Gem" and the yellow variety "Yellow Gem" are as tree-flowering as the ordinary tall-growing Arums? Also where a plant of the yellow variety can be obtained, and at what price? — ALEX.

5483.—**Hydrangea paniculata.**—Will someone kindly give me directions as to the propagation of this particular variety, whether by grafting, layering, or by cuttings of hard or soft growth? I have tried to propagate it in the same way as *H. hortensis*, but have failed.—C. V. SELWICK.

5490.—**Unsatisfactory Lilies.**—Will someone kindly tell me the probable reason that, although my lilies last year had a grand many buds, but few of them opened flowers, the others dying off before opening? Also what treatment to give them?—P. MARRAS, *Milford-street, Hereford.*

5491.—**Planting Potatoes.**—Will someone of your readers please say what quantity of Potatoes shall require to plant a piece of ground 80 yards long by 30 yards wide, half early, the other half second early, and late sorts? What are the best Potatoes for a dry, sandy soil, and the best manure?—L. BARNER.

5492.—**Scotch Briers.**—Will someone kindly tell me where I could get Scotch Briers, and the names of some of the best, and also best time to plant them? Also the names of a dozen of dwarf Roses for pots to stand in a path out-of-doors? Special qualifications, hardy, dwarf, and free-blossoming.—A. HOSKINS.

5493.—**Oothamnus rosmarinifolius.**—Will anyone kindly say if the "Seph" bush of Van Dyman's Land (*Oothamnus rosmarinifolius*) would be suitable as a substitute for a real greenhouse? Or would it live and thrive in the open air in a ivy, sheltered place in the North of Scotland?—P. M. Y.

5494.—**Grubs and vegetables.**—Will anyone tell me the probable reason that last year all my Lettuces and Celery were attacked by very minute grubs, and at the roots? What treatment does the soil require to prevent this? The soil is loamy and not very well drained.—C. McFARLANE, *Milford-street, Hereford.*

5495.—**Tea Roses for sale.**—I am going to plant three Tea Roses, the blooms of which I shall require for sale. Are the following good, reliable, free-flowering sorts, or would someone kindly recommend me better ones for the purpose? Marie Hardy, Ethel Brownlow, and Marie Van Houtte?—E. S. BRIDGE, *Widmore, Notts.*

5496.—**Electricity and plant growing.**—Will someone kindly give me some information as to the success or otherwise of electricity for growing crops? Is there any little manual published on the subject? I should like to know whether it is proved that crops thrive better under the electric light?—FRANZ G. TUBNER.

5497.—**Heating a brick pit.**—Is it a fine a good way of heating an ordinary brick kiln of four or six kilns? If so, should it be placed along the front? Is 9 inches steam large enough for this? What is the best thing to cover it with? Lastly, how far below the level of the fire should the fire-bricks be placed?—HOSKINS.

5498.—**Culture of Vegetable Marrows.**—I should be glad to get information about the cultivation of Vegetable Marrows; My Marrows last year all bore male flowers, then all female flowers. How can this be remedied so as to have the blossoms properly fertilized during the warm weather?—THOMAS LEANE.

5499.—**Propagating variegated Holly.**—I shall be glad to know how variegated Holly should be propagated? I understand that if the berries are planted the result will be the common green Holly. If it is gradual, what time is best for doing it, and should the stock be transplanted and grafted the same year?—S. C.

5500.—**Treatment of Streptocarpus.**—This is, I think, about the only plant that I have never seen an article in in GARDENING. Would someone now kindly favour me with a general sketch of treatment from seeds or cuttings to flowering point and after? I have a packet of *Streptocarpus hybridus* seed, about to be sown.—D. L.

5501.—**Ghlopiogon Jaburan variegatum.**—I have seen this mentioned in GARDENING as being good for a room. I have procured a small plant of it. Being only an amateur gardener, I shall be very glad to have some suggestions as to its treatment, and to what species it is most like. It is long, and does it like plenty of light and sun?—C. H.

5502.—**White growth on soil in pots.**—I have been troubled lately by a white growth all over the surface of the soil in some of my pots, much like the white mould that appears in a damp cellar. Thinking it came from using the same Ghano I discontinued this, and have not seen it since. Was this the cause of it, and, if so, why?—AUNT J. WATSON.

5503.—**Beds of Begonias.**—I am anxious to have beds of Begonias—the large-flowered ones, I mean—in this summer. Will seeds sown now be ready in the summer, or should I get small plants or tubers, and what are the names of good sorts, different colours—but darker red especially? I shall be most grateful for any advice on the subject.—G. L. H. D.

5504.—**Growing Tomatoes.**—I am putting up some glass-houses for Tomatoes on land that has been lying in Grass for about twenty-five years, and have no larval manure to put into the borders. Would "B. C. R." or some other Tomato-grower, advise me as to the best manure to use, and in what quantity to give both before and after planting?—G. GAZARD.

5505.—**A Mushroom failure, &c.**—I purchased four loads of horse-manne from some stables where peat-moss is used as litter for the purpose of Mushroom-growing, but have been unsuccessful. Will anyone kindly inform me if this manure is ever successfully used for Mushroom growing? Also what crops will be most benefited by the use of the aforesaid four loads of manure?—B. W.

5506.—**Hedge for a wind-guard.**—I am about to plant a hedge on light soil to serve as a wind-guard in a kitchen garden, and to perform that service as speedily as may be. I was about to use Privet, but was checked by the denunciation of it by A. H. J. on page 674. Would he or anyone else kindly suggest a better thing, bearing in mind the insalubriousness of quick growth?—FRANK.

5507.—**Unsatisfactory Celery.**—Every year my Celery when dug up has ugly looking marks all about it. I cannot feel satisfied as to whether it is caused by insects in the Celery or by grubs in the soil. Will someone kindly inform me and advise? Soil, moderately light loam, open position, sloping to N.W. Celery is from some of the best good stalks, well cultivated, and good of the soil.—W. H.

5508.—**Soil for Tomatoes.**—Is it necessary to change the soil every year in a greenhouse for Tomatoes? I have been told that if grown in the same soil the second year they are liable to disease. My houses were built for Tomatoes, and had fresh soil put in the borders that year, and they were successful. It seems a great labour to have to change the soil yearly.—ANNIE R.

5509.—**Weight and value of cow-manure.**—I have got some fresh cow-manure without much litter in it; the litter is fallen leaves and old-straw, and exposed to the weather in an uncovered yard. As I have no way of getting at its weight, perhaps someone will give a rule as to how many cubic feet should go to the ton, and the value per ton of manure in a covered and uncovered yard?—T. L.

5510.—**Plants for the banks of ponds.**—I am making some ponds. They are to be puddled. The ground is heavy clay, but the banks of the pond will be covered with good earth about a foot deep. Will someone kindly tell me what to plant on these banks? I want something ornamental and interesting, either in plants or Grasses in order to prevent the sun cracking the banks in the hot weather.—C. C.

5511.—**Treatment of Eonymus.**—I have seen the Eonymus mentioned in GARDENING as cutting the scaly branches at the seaside, and having some of my own which were planted this last autumn, but they do not look quite as fresh as they should, I write to ask if a overhead watering of salt and water would be of any use? If so, what proportion of salt and water should be used?—L. C. H.

5512.—**Liming a kitchen garden.**—I should be glad to see some information as to the application of lime to a kitchen garden. When should it be laid on, and in what quantity? If four days should it be dug in? What sort of lime should be used? The soil is a stiff clay for the most part, but a portion is a light loam. What is the special benefit of applying lime? Is it desirable in all cases?—ANNIE R.

5513.—**Kitchen garden for profit.**—I have an excellent kitchen garden and borders round the inside of the walls upon which several of the fruit-trees are trained. Will someone please inform me the best way to make a profitable use of the same so that the vegetables can be raised and sold, the proceeds to assist in paying the expenses? In short, what are the best kinds of vegetables to grow?—E. H.

5514.—**Crimum bulbs.**—In September last I received some Crinum bulbs from India and put them into a small greenhouse with a temperature of about 80 degs. They have not yet shown any signs of growth, though they are all quite hard at the base, and are not in any way rotting. Perhaps someone will be able to tell me when the bulbs should begin to grow, and give me some hints as to their proper treatment? It may be they require special soil?—ANNIE R. GARDNER.

5515.—**Pear Louise Bonne of Jersey.**—I should be glad if someone would kindly tell me the matter with my Pear-tree of a nursery, and the bark is swelling up so that I can peel it off. It is not planted more than 6 inches deep, and is a pyramid. I should like to know if this is a disease called canker, or is it scale? If it is either of these, will someone be kind enough to tell me what I can do with it to cure it?—J. J.

5516.—**Treatment of a lawn.**—I shall be greatly obliged for the advice of "J. C. C." or other good authorities, as to the right treatment for a lawn which has been recently planted, but which is now the worst of it. I had almost all Moss, What should I use now to kill the Moss, and what should be applied as a dressing preparatory to sowing Grass-seeds over it in March or April? The soil is partly sand, partly loam, and this Mossy turf must have come from some unimproved part.—J. E. L.

5517.—**A mossy lawn.**—My lawn is in parts so thick with Moss that the lawn-mower will not work on it. I see it is recommended in GARDENING to one of your correspondents similarly situated to plough it all up and re-sow it. But that would be a great disfigurement and the loss of a season. I have just had a parcel of seed in a earthen pot. Most and sow the land with a bushel of seed in a earthen pot of saw-dust. How would it be to do this, or is there any other substitute that would be better?—V. M. MOSE.

5518.—**Tuberoses.**—I have just potted 24 Tuberoses in 48-inch pots (one in a pot). After putting watered them and placed them in an unheated house on the stage, the pots resting on a bed of ashes. I put about 1 inch of Cocoa-nut-bark around each bulb to keep them moist. Would it be wise in a week or two to remove a few and put them in a heated house on a shelf, as I have no heated room for planting the pots in? Would they be likely to blossom (unless plunging)? I want them to flower about August or September.—ANNIE R.

5519.—**Pelargoniums out-of-doors in a wet district in Sussex.**—If anyone please to state the best kinds of Zonal and Ivy-leaved Pelargonium, &c., for outdoor (summer) culture in pots and beds? The best time to put them out in the open air and the best manure of treating them as to soil, manure, &c., before and after this period? Would Seakale pots, if efficiently drained, be likely to answer well for the Pelargoniums? Would old cut-back plants be best for pots or would the usual autumn-struck cuttings do?—R. W.

5520.—**Deutzia gracilis.**—In the spring of last year I purchased one of the plants from a nurseryman, which after it had done flowering I stood in the open (in its pot), where it has been ever since. It is now starting into new growth, and I should be glad if any reader of GARDENING will give me information as to how I must treat it now? I have a small greenhouse (unheated), but the temperature is generally about 52 degs. by day at the present time, and about 50 degs. by night, through its being adjacent to a room of the dwelling-house.—READER, *Pinewood.*

5521.—**A small vinery.**—I am thinking of putting up a small vinery with a heating apparatus with the view of growing late Grapes for selling at about Christmas. My idea is to start the Vines and keep the heat going until the warm weather sets in. Could I then finish them off without further heat? Any advice as to varieties likely to succeed in the hands of an amateur and treatment, will be much appreciated. Is there a good cheap way of growing?

growing? Is it any use trying to grow late Grapes without fire?—P. MATHEWS.

5522.—**Growing Roses.**—Shortly before the 25th of March I shall be moving into a new house. In my garden I have two kinds of Roses, a *Chloire de Dijon* and a *Baronne Rothschild*—each from 23 feet to 3 feet high. In the new house I am taking I shall have a conservatory. Could I grow these Roses in pots there, and, if so, should I put them at once, before the spring advances? On the other hand, will they do better in a sunny, open border, and, if so, should I have them in my present garden until I actually want to move them? If putting is advised, please say size of pot, and also if the bushes should be cut back in the spring?—T. R. R.

5523.—**Climbing Roses.**—I have six Climbing Roses planted out in a bed in a greenhouse which I have recently painted. I intend starting them early in February. There will be bedding "Geraniums," &c., on the soil in the same house. I should like to know if I should syringe the Roses once or twice a day; also, what temperature should I maintain night and day (at heated hours), and whether I should shut about when the temperature rises above 55 degs.? I saw an article in GARDENING, Jan. 20, on forcing Roses, which says, "That if the temperature rises to 55 degs., or even more, this will be of benefit to the plants, but, on no account admit air."—ANNIE R.

5524.—**English guano for a garden.**—Late last summer I siphoned through GARDENING me to the best artificial manure for general kitchen garden purposes on ground which had not been manured for four seasons, although crops had been taken off it. Two of my correspondents replied in GARDENING, July 25th, recommending the application of soil in the autumn before planting the first of the crops, which advice I duly carried out. This dressing of soil was to be followed in the spring by the use of English guano. Might I ask for a few more particulars of this English guano, and where it is to be obtained? Perhaps also some one else would give his experience of it as a fertilizer.—R. H. R.

5525.—**Gold-fish.**—Will someone kindly give me some hints upon the keeping of Gold-fish in perfect health in a bell-glass, six 9 inches deep by 10 inches diameter at the top. If any wood required, what quantity, and of what sort? Can town water be used, and how often should it be changed? Would the gold-fish be fed by the same means as in a tank? How often should they be fed, and with what? Would a fat glass cover, raised about an inch above the top of the bell-glass, exclude too much air from the surface of the water for the health of the fish? How long should the water and plants stand before the fish are put in? How many fish, 3 plants or 4 inches long, can be kept in this sized glass?—K. H.

5526.—**Roses in pots.**—I have just taken up from open ground some dwarf seedling Briar-headed Tea Roses and put them into 8-inch pots and placed in a cold frame. I do not want the blooms to have any wax, January or February, I have a green house, but I do not want to have them during the winter. The plants are very strong, about 1 1/2 feet high. I should be very much obliged if "J. C. C." would say when I should prune and when repot them, and if they should be cut in hard? I would keep them in the greenhouse all the summer if that is the better plan; but my greenhouse faces due south, and is a lean-to, and gets so hot that the only thing I grow in it during summer is Tomatoes. Names of dwarf Tea Roses, and names of the best of them, Hulse, Innocent, Pinks, Ethel Brownlow, Elizabeth Gilbert, Souvenir d'un Ami, Souvenir de Therese Lavelle, The Irish, and Catherine Mermet.—J. W. R.

5527.—**Japanese Chrysanthemum.**—I have about 300 Japanese Chrysanthemum variety, mid-season, and late, which I wish to grow for exhibiting cut flowers, so require quantity of bloom rather than quality. I have an room to grow them throughout in pots, and as I am away from home a great deal during the summer and an single-handed, have not much time to devote to my plants. I am thinking of growing on 6-inch pots without stopping, planting out in the open air in a half border in April, and digging down to within 5 inches or 6 inches of the soil in May or June, according to varieties, letting them grow on after cutting down without stopping or thinning till the autumn, and then potting up. I wish to keep the plants as dwarf as possible and want plenty of bloom. I would feel obliged if any of your correspondents would say if my proposed plan will answer, and any hints on general culture of Chrysanthemum in the cutting-down system when grown in the open will be gratefully received?—T. W. R.

5528.—**Heating a vinery.**—I have a vinery 100 feet long, heated by a saddle boiler. The furnace to heat this boiler consumes such an amount of coke that I am anxious to discover if some economy in fuel is practicable. On two occasions in the last few days I have found the thermometer at 78 degs. at eleven o'clock a.m., and the ventilators have then been opened to reduce the temperature. I find that the garden boy who wakes the fire pot on a shovelful of coke every hour during the day. My garden boy says that 100 degs. of heat will do harm during the day if the fire is on; though I tell him that I cannot believe such a difference in temperature between that degree and 45 degs. at night can be anything but harmful. Will someone kindly inform me what I might do to? Could not the fire be let out during the day when the weather is fairly mild, and lighted again in the evening? At present my furnace burns about one ton of coke in three weeks. Are not these great variations of temperature injurious? And is there not a great and unnecessary waste of heat at present? I have a good many plants in the vinery—Roses, &c. The vinery is divided into two equal parts, and the heat can be shut off from either in portion.—F.

5529.—**An old orchard.**—I have some in possession of an old orchard, which appears to have a clay and marley subsoil; there is a large pond in the centre which evidently drains the orchard. There are about 150 large and small fruit-trees: Pears, Apples, Damsons, Plums, and many others. The whole is walled in with brick walls. It has been neglected by many years, having been in Chancery. The walls and Nettles were up into the branches of the trees, the bark of which is covered with a coating of green Moss, quite a Sycagee in parts. I should like also to put in about 20 cuttings of every tree, and had about 20 inches of soil off every row passing round it, and to put in about 20 feet of the trunk. I have

taken the Grass-roots from an old meadow and put them in the trench and around the trunk, preciously pulling some old lime and mortar over the fibrous roots. It is now proposed to put a quantity of ash-indeed manure around each tree and whitewash the branches and the trunks with a solution of hot lime, containing a small quantity of paraffin. It is further proposed to cut them well in and to prune them in the usual manner. Will someone kindly inform me whether such a course is proper under the circumstances, and, if not, what other could be suggested? Assuming that the above proposals are carried out, would it be probable (other circumstances being favourable) that a good quality of fruit can be expected this year?—E. R.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

530.—An Orchid book (K. S.).—The "Orchid-growers' Manual" is the best one I can recommend for your wants, published by B. S. Williams, Upper Holloway, London, N.—M. B.

531.—*Thalassopsis Schilleriana* (H. Bax.).—Yes, there is a white variety of this plant, and it is known by the name of *cecalis*. It is, however, very rare. The flower you send is certainly not it, the sepals and petals having quite a shade of rose upon them.—M. B.

532.—*Acacia Oxycardus* (J. B.).—This is the name of the species sent. The flowers are closely set upon the spikes and are of a deep, rich yellow. It is a species which, flowering in winter, should be more frequently seen than it is; indeed, there are a great many *Acacia* and other fine plants which are now past on one side or the other.—J. J.

533.—*Dendrobium nobile* (J. W. W.).—This is a very fine form of the plant. I suppose the cause of its flowering so early, before the other growths, arises from the fact of its being fully exposed to the sun during last summer. I advise you to put the growth off, as it will be of no more use, and it will add to the compactness of your plant.—M. B.

534.—*Epidendrum invarsum* (J. M. W.).—This is the name of your plant, which is not a common one in cultivation, neither is it showy. The flowers before they are creamy white, with a few purplish spots at the base of the sepals and petals; the flowers are fragrant. The plant is a native of Brazil, and requires to be grown in the Calcey-house.—M. B.

535.—*Cypripedium Haynaldianum* (H. B.).—I can excuse you for mistaking this species for *C. Lowi*, for they are much alike; but this species flowers earlier than *C. Lowi*, the dorsal sepal is more spotted than in the last named species, and also the petals are more spotted at the base. It is a very fine species, each scape bearing from four to six flowers. Being a low-country plant it requires a good deal of heat.—M. B.

536.—*Trachelium coeruleum* (Trachelium).—This plant is a member of the "Campanula" family, and is a hardy herbaceous perennial, delighting in sandy loam and leaf-mould. It is commonly known as *Throatwort*. It comes from Italy. I do not know where my friend will get it in the trade, but the most likely places would be Messrs. B. Kitchin's, of York, and Mr. T. S. Ware, of Tottenham. I am sorry to state that I have no plants of it.—M. B.

537.—*Odonoglossum Alexandræ Regine*.—*T. J.* sends me a beautiful spotted flower which I think must be this variety. It is a magnificent blossom, the sepals and petals heavily spotted with rich-brown and tinged with purple on a ground of white. The flowers, although very beautiful, lose somewhat in effect here, the sepals and petals being narrow; nevertheless it is a very pretty curio, even in the spike; it requires just the same treatment as the typical plant.—M. B.

538.—British Ferns (G. Webb).—If you intend these plants for exhibition purposes you do not require very small-growing kinds, but some good and handsome ferns of *Adiantum*, *Polystichum*, *Polypodium*, *Lastræa*, and *Scolopendrium*. You should grow quite ten dozen kinds, so that you might have a choice of variety, and perhaps when you require to take a dozen for public exhibition you will then have a collection fit for respect for competition. I do not consider anyone has a chance of winning with only the number required.—J. J.

539.—*Oncidium varicosum* (G. Wign.).—This is the plant of which you need me flowers, and it is not the rarely known as *Rogersi*. I should imagine in the numbers of this variety that would appear to be none in the country that was very common for me instead of one of the very rarest. It is very common for me instead of one of the very rarest, spotted with reddish-brown, the lip being bright yellow. It comes from San Paulo in Brazil, large and introduced here nearly 60 years ago. It requires to be grown at the root end of the Calcey-house in the winter, but in the summer months it may be grown with the *Oncidoglossum*.—M. B.

540.—*Coccygia Dayana* (J. Manning).—This plant very much resembles *C. Massangeana*, and it is a capital plant to grow in company with it. It is now about ten years since in this country, and is one of the introductions of Messrs. Veitch and Sons, Chelsea. I prefer it growing in a basket hung up near the roof-glass in the East Indian-house. It requires a liberal supply of water during the growing season, and during the resting season less will be required, but I always like to keep it supplied with enough at this time even to maintain the buds and leaves in a healthy, fresh condition. It should have good exposure to the light, but be shaded from the sun during the hotter part of the day. This, I think, will answer the questions asked.—M. B.

541.—*Dendrobium superbiens*.—*J. W. W.* sends me flowers of this species which opened late November in perfect condition, which leads me to say it is one of the most desirable species from the Torres Straits. The plant is sometimes called an *Australian species*, but I think we had more confirmation of its being found in the Australian island. It apparently is found on the islands which abound in the Pacific Ocean.

It is a beautiful, free-flowering plant, the blooms being each about 2½ inches across, the sepals being rose-purple, knitted with veins somewhat deeper in colour, narrowly bordered with a white margin, the petals and lip being of a rich-crimson-purple. It is a plant, however beautiful, I somewhat hesitate in recommending my readers, for it will not succeed without strong heat.—M. B.

NAMES OF PLANTS AND FRUITS.

* * * Any communications respecting plants in fruit sent to us should always accompany the name of the fruit, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, W.C.

Names of plants.—*J. B.*—*Maranta zebra*.—*A. P. W.*—*Philibodium australe*.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name five varieties at a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of fruit.—*T. R.*—Apples local kinds which we cannot name.—*S. R. T.*—Apples *Asimonia's* Kernel.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

J. J., *Alphruth-road, Liverpool*.—How to haul Roses has been described many times in back numbers of GARDENING, but the best way to learn how to do it would be to get a neighbouring gardener to come in and show you.—*Santa Rosa*.—Apply to Messrs. Williams Paul & Son, Waltham-street, Herts.—*T. P.*—Apply to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, London, N., or W. Messrs. Baskin & Son, The Nurseries, York.—*Faber*.—Look on "Conifers." Apply to Messrs. James Veitch & Sons, Royal Exotic Nursery, King's-road, Chelsea, London, S.W.

Catalogues received.—Price List of Seeds, Messrs. Dobbie and Dick, 66, Deansgate, Manchester.

THE SUFFERINGS OF LONDON HORSES ON LONDON PAVEMENTS.

TO THE EDITOR OF "GARDENING."

SIR,—I was a witness this morning, as I often am, of the struggles, sufferings, and nervousness of some fine earl horses trying to move their loads over the wood-pavement. This is a very dangerous pavement when caught by ever so slight a frost, and if the men responsible for it were themselves yoked, with iron shoes on, to a load of coal, and had to bring it up or down Piccadilly in a slightly frosty morning, they would probably soon get a just notion of the value of this worst of pavements. No road pavement should ever be laid down without thought of the animals that have to move our enormous traffic. London has the noblest specimens of the draught horse of any city in the world, and thousands of them, and yet we are so cruel as not to give them a safe foothold. At least one thing might be done to modify this suffering. In all great roads of traffic—say, like the Baywater-road if a slip of small net and well-set granite were put alongside the wood, it would give the horses a secure footing in case of light frosts and grassy slush of the wood. If we took as much trouble in set granite in small cubes as we do these forests of imported wood, we should get a far more enduring and clean roadway than we ever can from dirt-soaked wood which often ruts into holes in a few months. W. R.

Stupid work in St. James's Park.

The same kind of groundwork to which (as carried out in Hyle Park) you allowed me to draw attention recently is also now being done in St. James's Park. In front of the harnack, for example, there is a building-like mound of earth with the trees deeply embedded in it. As, however, there was evidently some fear that the trees would be injured, a collar of bricks has been placed round the base of each tree, out of which it emerges! In the east end of the park the same process is going on, the tree boles being embedded as usual. Many of the finest trees in St. James's Park come out of the ground in these stone collars. One of the most beautiful things in tree life is the way that old trees rise out of the ground; the union of strength and beauty of form which one may see in the old Oaks, Lombardy Poplars, and many other trees, is completely hidden in St. James's Park. It is a very stupid work, it is a very stupid

work, needless, and degrading to landscape gardening. The parks of London are its most precious possessions, and no such thoughtless work should be done in them. St. James's Park for a low garden has many advantages, some excellent views, and there is nothing about it which wants hiding as the hen-houses might in a villa garden. The line of the earth's own surface here is better far than that of the earnest effort of the earth-moving gardener.—W. R., in Times.

12 ROOTED CHRYSANTHEMUM CUTTINGS.—Good free for F.D. 16. 1d. Twelve distinct varieties, all free flowering, correctly named, just ready for growing.—A. GRUBBS, Nurseyman, Redlich.

MILLER'S VICTORIA ANTER.—Gigantic gorgeous double flowers, mixed, 3s. and 6d. pkt.; six beautiful varieties, separate, 1s. 6d. Large-flowering German variety, *Stuck*, typically double fringed flowers of brilliant colours, mixed, 3s. and 6d. pkt.; six beautiful varieties, separate, 1s. 3d. *Phlox Drummondii*, large-flowered, mixed, 3s. and 6d. pkt.; six beautiful varieties, separate, 1s. 3d. All good free. Illustrated Seed Catalogue, free.—F. MILLER & CO., 267, Abchurch-lane, London, S.W.

GRAPE VINES.—Fine fruiting canes in pots, 2s. to hear them 15 hundred at once, 6s. 6d. each; 3s. for 6. (See, p. 6.) All Fruit-free, wholesome and reliable.—WILL TAYLER, Nurseries, Hampton, Middlesex.

100 ORNAMENTAL CONIFERS.—Flowering Shrubs, and Chittams, from 9 inches to 2½ feet, 20 distinct varieties for 10s. 6d., carriage paid to railway station, including *Colinus Dodonæi*, *Pinus Bungeana*, *Abies Chrysaea*, &c., all good and healthy.—HENRY & CO., near Ansonbury, Bucks.

AMPELOPIS VITICOLA, 4, 1s. 3d.; *Wistaria*, 3 for 1s. 4d.; *Bignonia radicans*, 4, 1s. 3d.; *Climbing Roses*, 4, 1s. 2d. All good strong plants, all free.—HENRY & CO., near Ansonbury, Bucks.

CARNATIONS.—Hardy Border, leading varieties, good rooted layers, 12, to include the new *Caroline Dufosse* of Portland, *Germania*, *Mrs. Muir*, *Mary Murray*, *Pinkhurst*, and *Chambrone*, 3s. 6d. free. Select List of all the leading varieties, free.—T. SEARLE & SONS, The Nurseries, Wiltshire.

DENDROBIUM THALASSOPSIS *Schrederi*.—Anum, bigibulum, undulatum, &c.—We offer an importation of these at 1s. 2d., 6d., 5s.; carriage 4d. extra. Warranted true. Catalogue free. LITTLEBIRTH & CO., Romford, Leeds.

1,000 RIVAL AND SHOW CHOICE.—Named Pelagic plants.—Vigorous bushy plants to make good specimens for summer bloom, including such grand varieties as *Gollinice*, *Mabel*, *Volante*, *Nationale*, and many others equally distinct and good, 3s. 6d. per doz. Cash with order. 2 small double *Peonies*, gratis with each *Salicetum* guaranteed.—J. W. COLE, Florist, Milland-road, Peterborough, East Angles. "Plants received this morning give every satisfaction."—S. B. Hackney.

18 PACKETS CHOICE HARDY FLOWER SEEDS, post free, 1s. 3d. A very special offer.—BRADLEY BROTHERS, Huddersfield, Lincoln.

TROPÆOLUM TUBEROSUM.—Brilliant orange and scarlet flowers, early grown flowers all summer, 4s. 6d. free.—LANSNER, Bryn-sudor, Co. Down.

A FEM FOR HANGING BASKETS.—Trailing Bellflower (*Campanula trachelium*), wreath of finely salver-shaped blue flowers; freely given. Three good plants, 1s. free, with cultural directions. Now in best time to plant.—J. HUN RAYNER, Highfield, Southampton.

THE SCARLET AND GOLD CLIMBER (*Tropæolum tuberosum*), robust growth, rich foliage, brilliant flowers; colors golden, table, lutton-hole; succeeds in poorest soil. 2 good roots, 1s. free with directions. Now in best time to plant.—E. A. YER, as above.

GLANT WHITE MARGUERITE (*Chrysanthemum maximum*).—Floury-hairy, and suits only to be once planted to yield profusion of large flowers year after year. 3 good roots, 1s. free, with directions. Now in best time to plant.—HAYNER, as above.

THE SCARLET COLUMBINE.—Distinct, striking, and elegant. Absolutely hardy and easy to manage. 3 well-rooted plants, 1s. free, with directions. Now in best time to plant.—HAYNER, as above.

CHRYSANTHEMUMS, strong cuttings, *Mad. Desgrange*, 10s.; *Mrs. Hawkins*, 1s. 1,000 free. *Conchoid*, 10s. 100, all free, of 2s. 100.—PEARLNEY, John's V.L.B., Bromley-road, Hampton Hill.

CHRYSANTHEMUM CUTTINGS.—Earliest and latest market and exhibition varieties, truly named, 3d. per doz, free, carefully packed.—HARVEY BROS., Huddersfield Nurseries, Enfield.

PERNS! FERNS!—40 rare roots, 16d., free. It includes—*Maudslayi*, *Ceterach*, *Adiantum*, etc. Just the time to plant.—H. ANDREWS, Sluice, Achnacree, Devon.

LILIES OF THE VALLEY.—Strong flowering plants, suitable for pots or bedding, 1s. 6d. 100, free. Yellow Brown, 1s. dozen, free.—A. SIMMONS, 65, East-end, Huddersfield.

ORIOLENE CRISTATA.—A fine variety, well grown and cheap, plants with 15 buds, 1s. 6d.; strong, 2s. 100, 3 to 5 spikes, 3s. About 70 buds, 7 or 8 spikes, 5s.; stronger, 10 to 150 buds, 12 to 20 spikes, 7s. 6d. to 12s. 6d. each.—Trustees late J. STEVENSON, Timperley, Cheshire.

CHRYSANTHEMUMS.—G. W. Chills, plants, 1s. 3d.; one dozen, Exhibition plants, 2s. 6d.—ALFRED JONES, 29, Church-road, North-on, Dudley.

WINE-ROOT TEA ROSES.—*Olivier*, *Mermot*, *Aline Soley*, *Goubaud*, *Paolo*, *Margottin*, *Naboumard*, *Maria Ward*, *Heile*, *Hendley*, *Govatt*, *Glasgow*, *Willems*, *Wendell*, *20s. 100*. Purchaser selection, 6s. 100, free for cash with order.—DAWBRE, Hunt & Binge Lodge, Glyceray, Cheshire.

DAHLIAS.—Pot roots of Show, *Caecus*, *Pom-pone*, and *Single*, choice named sorts, 10, 2s. 9d., 20, 5s. Many plants, strong Show and Fancy, named var., 12, 1s. 6d.; 24, 2s. 6d.; 50, 4s. 6d. Sun free for cash.—WILLIAM JACKSON, Field, Kettlewell, Whaleybridge, Stockport.

DAHLIAS.—Pot roots, double and *Caecus*, *Single*, 60s. *Chrysanthemum* cuttings, good kinds, 50, 2s. 100, 100, 100.—H. WARD & SONS, Waltham-street, London.

CHRYSANTHEMUMS.

POMPONS FOR EXHIBITION.

POMPON and Anemone Pompon varieties of Chrysanthemums are particularly adapted for amateurs whose space is often of a limited nature. Not only do they require smaller pots than the Japanese and incurved sections, but they do not grow nearly so tall as the bulk of the sorts belonging to the named sections. Apart from these considerations, Pompon and Anemone Pompon Chrysanthemums are much preferred to any other kind by reason of their prim neatness and refinement, and also for the free manner in which they flower when cultivated as bushes. In this form they can be kept quite dwarf. My intention in this article is, however, to confine myself to the method of producing exhibition blooms. Opinions differ as to the manner in which the cut flowers should be staged for exhibition, whether in bunches of three blooms, one on each spike, supported several inches above the stem to show the foliage, or in bunches comprising an undefined number of flowers without any disbudbing. The former I regard as the most satisfactory, for under what is termed the "big bloom method," the real character of the variety is brought out, both in size, form, and colour. The foliage too is much better, which enhances their appearance, and in staging for exhibition a much more uniform stand can be obtained than by irregular-sized bunches. It is also much easier than for judges to determine the merits or demerits of a stand when an equal number of blooms are staged in all stands. Those possessing the greatest individual quality are bound to win. Like all other sections where quality of the blooms is the leading point, the plants require a long season of steady, uninterrupted growth to allow the shoots to mature properly. From such as these only can the best blooms be had. Cuttings should be inserted at once. If two are put into one 2½-inch pot they are easily repotted by dividing half the soil carefully to each. In this manner no great check is given to the plants. At this time of the year roots are more quickly formed than during the dull days of December. Under handlights in a cool house or even a newly-started vinery or Peach-house are good places to strike the cuttings in. Wherever they are placed they should be kept air-tight in the frame. A layer of coal-ashes on the stage under the handlights is the best means of affording this requirement. A cool, moist bottom is also assured. If the position is fully exposed to the sun the cuttings will require shade, especially if the leaves flag. The more this is allowed the longer they will be in making roots. Directly the plants are furnished with roots and will bear exposure to air and sunlight without the leaves flagging, remove them to a

SHIELF CLOSE TO THE GLASS in the same or another cool-house, where they can obtain abundance of air to prevent the growth being drawn up weakly. Do not top the plants, but allow them to grow till the first break occurs, when four or five of the strongest branches

should be selected, removing the others, also all shoots as fast as they appear from the main stems. Should a second break occur by the formation of a flower-bud early in August, the bud and the shoots must be again taken off, retaining only those branches which were selected at their first break, except that four more shoots may be retained to each plant, making in all eight to ten blooms on each. If the break occurs during the last days of August rub out the shoots then made, and retain the flower-bud formed at the end of each branch. These will produce large and well-formed blooms if all other details are carried out. Continue to pinch out any superfluous shoots that appear, so as to concentrate the whole energy of the plant into the selected buds. Pots 8 inches in diameter are quite large enough for Pompons, the soil and manner of potting to be the same as for the other sections, instructions for which will appear in GARDENING as occasion necessitates. House the plants from five to six weeks prior to the time they are required to be in bloom, placing them in a light position as near to the glass as possible. For the first shift from the cutting pots into those 4½ inches in diameter use the following compost: Two parts fibry-loam, one part leaf-soil (if available), and one part horse-mannure partly decayed. If leaf-soil is not to be had use an extra quantity of horse-mannure, adding a small portion of wood-ashes. If the loam is inclined to be heavy in texture add coarse silver-sand freely, but if of a sandy nature very little sand will be needed. At

ALL STAGES OF THEIR GROWTH provide plenty of space between the plants so that they may not be drawn up weakly, but be at all times stocky in growth. The following is a good selection of varieties in both sections:

POMPONS.—Black Douglas (rich dark-crimson), Charles Dickens (gold-tipped rose), Comte de Morry (bright purple), Golden Mlle. Marthe (bright golden-yellow), La Perette (white), Lizzy Holmea (canary-yellow, tipped-rose), Mlle. Elise Dardan (soft lilac-pink), Mme. Marthe (white, full solid bloom), Marabout (white, fringed florets), Mrs. Bateman (orange-brown), Nellie Rainford (buff-yellow), President (dark-rosy-crimson), Pygmalion (deep-rose), Rosiate (blush-rose), St. Michael (rich-gold-yellow), Volcan (deep magogany-red, florets tipped gold), William Sabey (canary-yellow, quite one of the best), William Kennedy (rich-crimson, shaded anaranth), William Westlake (rich-golden-yellow, suffused with a reddish tint), Maid of Kent (white).

POMPON ANEMONES.—Antonina (golden-yellow), Astrea (lilac guard florets, bluish disc), Calliope (ruby-red guard florets, red disc), Mmc. Chalange, bluish guard florets, bluish shaded sulphur disc), Mmc. Montels (white guard florets, yellow disc), Marguerite de Coi (bluish guard florets, yellow disc), Marie Stuart (pale-lilac guard florets, sulphur-yellow centre), Regulus (cinnamon guard florets, brownish disc), Perle (rose-lilac guard florets, pale-rose disc), Sidonie (lilac guard florets, bluish centre), Queen of France (rose-crimson), Bossio Flight (sport from Mmc. Montels, but of a deeper colour), Emily Rowbottom (cream-white sport from

Marie Stuart), Magenta King (magenta guard florets, yellow disc), Rose Marguerite (bright-rose).

5327.—Japanese Chrysanthemums.

—Rather than cut the plants down in May or June, as suggested, it would be better to top the plants when 4 inches high in the pots, and again when 5 inches more of growth has been made. After this allow all shoots to grow away at will, and all buds that form to develop blooms. The plants must not be crowded during any stage of their growth, especially while they are in pots. If the plants have not space to extend their growth properly, and not given abundance of air the shoots will be drawn up weakly, they will not produce nearly so many flowers, and must of necessity grow much taller. Gradually harden off the plants in frames before planting them out. "Traveller" must be guided by the locality as to whether they can be safely planted out in April or not. It is not wise to be too venturesome in this or the points of the new shoots might get nipped by frost. Such an occurrence cannot be any benefit—rather the reverse. Do not plant them in soil that is rich—a too luxuriant growth is not favourable to free flowering. Much better give the plants one or two copious soakings with liquid-mannure, if the growth is not being freely made. What is wanted to give a quantity of good blossoms is a free and matured growth. Place a stout stake to each plant when the shoots are 1 foot high, as growth proceeds. If the branches are allowed to fall on to the ground and there lie, as is very often the case, the appearance of the plants afterwards is not enhanced by the crooked state of the branches. Early in September cut around each plant with a spade at a distance from the stem as will allow for potting. When the plants are lifted for potting at the end of the month, they will not then feel the check nearly so much as though they were dug up direct and potted. A position behind a north wall will suit the plants for a week or so after potting, syringing them twice daily to prevent flagging.—E. M.

5497.—Electricity and plant grow-

ing.—The late Mr. Siemens tried experiments with electricity in growing flowers and fruits. I do not think it was ever stated what result was arrived at, but I expect it was only partially successful, as nothing has been heard of it since, and if electricity could have been usefully applied something more would have come out of it before this. I think the idea current then was that plants under the influence of the electric light would grow night and day, or, rather, the progress would be much greater. But would the plants stand the unnatural excitement? This difficulty was not settled by the experiments in question. No doubt plants will be much healthier in houses where the electric light is used, as it does not sear and vitiate the atmosphere in the same way that gas does, and therefore the use of the electric light becomes a general plant culture in houses will be much easier and more successful.—E. H.

GARDEN WORK.

Conservatory.

The cuttings of Chrysanthemums are now pretty well all put in, and the early-rooted plants are ready for shifting into 5-inch pots; a cool air, however, is the best place for them now till it is safe to place them in a cold pit, which will be shortly. Everybody should grow a good group of Mme. Desgrange; it is one of the best and most useful of the early-flowering varieties, and if the buds are thinned the flowers come much finer. Winter-flowering Salvia are deserving of more consideration than is given to them; by growing several varieties a long succession of bloom can be had with very little trouble, as all one has to do is to strike cuttings now and pinch the leading shoot a few times, and plant out in an open situation end of May, and pot up in September. Splendens, Brucati, Pitehri, Bethell, albo-corulea, and gessneriflora are all good; the last named is a late bloomer. Late Cinerarias just coming into bloom will be improved by liquid-manure. Those who have a good habited, large-flowering strain should save seeds from the best; they will seed freely in a cool house during spring, and the seeds will be ripe in time to sow for next season's blooming. There is very often a difficulty in getting seeds to a good state from the wholesale dealers. Stake early-flowering Pelargoniums; just enough stakes should be used to open the plants out and no more. Keep down green-fly either by fumigating or dipping in an insecticide. Promptitude in dealing with insects is very important, as when plants are badly infested it takes so much fumigating to clear the insects off. Azaleas, Indian and Japanese, are very prominent now in the conservatory; very weak liquid-manure will be beneficial to pot-bound plants twice a week or so. There are plenty of bulbs in bloom now, but there is nothing more beautiful in a quiet way than the groups of Freesia, which are flowering very well this year. After flowering the bulbs must be gradually dried off on a shelf near the glass, and then kept without water till August, when they can be re-potted. Young Cyclamens sown in autumn, which have been grown in boxes, should be planted in single pots, and as soon as the roots have worked through the soil, be shifted into 6-inch pots, and early in June moved to cold frames placed in a shady situation. Turfy loam and leaf-mould in about equal proportions, made fairly porous with sharp sand, will suit them. It is late now to sow Cyclamens for blooming next winter if really good plants are wanted. Plants raised now will bloom, but will not be as freely as if the seeds are sown in August or even earlier, and the plants kept growing steadily all winter. The bulb under this treatment grows strong enough to produce good foliage and abundance of fine blossoms. Lay in a good stock of loam, leaf-mould, peat, and sand for potting purposes. Drainage materials and clean pots will be required.

Unheated Greenhouse.

The White (Madonna) Lilies are now throwing up spikes; these will be charming towards May-day. In many gardens these are largely grown for the cool conservatory, and they will bear gentle forcing so as to get them in bloom by Easter in most seasons; but Easter comes early this year. Gladstone The Bride is a charming bulb for the cool-house; the bulbs can be plunged in Cocoa-nut-fibre till all danger from frost is over, and, if necessary, covered with paper on cold nights. Double Wallflowers, Brompton Stocks, Canterbury Bells, Clove and other Carnations, Mrs. Sinkins and Her Majesty (Pinks), Scarlet and other Anemones, and all the hardy kinds of bulbs will be in blossom or coming on now. On the whole, I don't think the owner of the unheated greenhouse has any need to envy those who have the care and expense of heated structures. The Christmas Roses have now pretty well done blooming under glass, but they must not be turned out till the weather is quite settled.

Stove.

Growth is becoming active now. Many Orchids, Ferns, and other plants will now or shortly require repotting. Healthy young plants with vigorous roots may be shifted on with a ball entire; but in some instances, doubtless, the soil will be sour, and the balls must be reduced. This is the season when plants will make new efforts to extend themselves, and the growth will require regulating to the extent, in some instances, of cutting back in order to get new growth from the bottom; this refers more especially to soft-wooded plants, such as Begonias, Fuchsias, and Stocks. Move relays of Tuberoses into heat to ensure a succession of flowers for button-holes and sprays. Shake out and repot Caladiums, using loam and old manure for the strong-growing kinds; the small, delicate sorts, of which argyrea may be taken as the type, will do better in lighter compost, freely mixed with clean, sharp sand. This last-named Caladium makes a beautiful dinner-table plant.

Pines.

Lay in a good stock of rich, turfy loam for repotting the general stock of Pines early in May; this will form the bulk of the material required. A little soot or bonedust, or very old manure must be used for the last shift, especially where comparatively small pots are used. If will also be necessary when the repotting takes place to renew the plunging-beds; it can be used in these should be got in and exposed to fermentation in an open shed, if possible, to fit it for making up the beds, and replugging the plants immediately after potting. Plants which are just throwing out fruita may have a little more heat, and liquid-manure may be given in a weak state every time the plants are watered. The plants should be looked over twice a week now, though it will not follow that every plant will need water so often. A good deal depends upon the construction of the house or pit and the heating. Sixty-five degs. at night will be high enough for the present; 60 degs. will do for successions and suckers.

Early Orapes.

The Black Hamburgs and Foster's Seedlings will now be thinned if started early in December, and if in pots more nutriment should be given. It is a good plan to

enclose the pots with rough turfy loam and manure. The roots will work out after 16, and then an outside compost can be substituted by the application of artificial manure; this is a better way of feeding them, keeping the roots within the pots and deluging the soil therein with strong liquids. Rub off all sub-laterals below the bunches, and there will be but little growth left beyond the bunches except the two leaves, which is usually as much as there is room for when the Vines are trained near. In the case of pot-Vines, where it is desired to obtain as much from the house as possible, the roots need not be trained further from each other than 2 feet. The Vines will be run out and young canes take their place next year. The hot-bed for propagating may be started now. Except a properly-constructed house, fitted with a tank for bottom-heat, there is no system of propagation better or cheaper than the old-fashioned hot-bed made large enough to keep up its heat for three months. The plunging-bed inside the frame may consist of sawdust or Cocoa-nut-fibre, and all plants except Pelargoniums may be propagated in such a bed with the greatest ease from this on to May or later.

Window Gardening.

When bulbs go out of bloom more them to a spare window, and give enough water to keep the growth fresh, so the ripening process may be a gradual one. Cuttings of Zonal and other "Geraniums" will root now in sandy soil. Do not crowd too many cuttings in a pot or they will damp off. Ferns which are starting into growth may be repotted in clean, well-drained pots; some of the old soil should be shaken away. Be careful in watering after repotting; let the roots feel the new soil before much water is given, and then healthy progress can be depended upon.

Outdoor Garden.

So far as regards the general collection of Roses, it is not too soon to prune, but Roses on walls and arches, where sheltered, may have the longest shoots shortened a little and the weakly shoots cut out. Roses on warm borders intended to produce early flowers for cutting may also be pruned, and newly-planted Roses which were planted with the wood unshortened may have the longest shoots reduced to relieve the strain upon the roots. This is perhaps a small matter. The principle of reducing the top in proportion to the loss of the roots soon after the plants are lifted is, I think, a sound one. Of course the plants will be cut back further later on. Anything done now or when the Roses were planted is only with the view of relieving the roots a little till roots begin to form, and as root-action, in the case of Roses, will take place almost as soon as the plants are firmly fixed in the ground, by the time the final pruning takes place the new roots are prepared to begin working. To improve the value of early-planting, I have replanted Roses which had been laid in in the autumn at various times during winter and in open weather; there is some movement of the roots to get a firm grasp of the soil. In another way this illustrates the value of firm planting. A plant loosely fixed in the soil cannot begin to work until the soil presses the roots closely, and unless the plants are firmly fixed in the ground by treading, the natural action of the soil taken time, and in the meantime the plants may die. I am persuaded a good many plants die from being loosely placed in the soil. Get all borders dug or forked over, and, if necessary, manured, to be in readiness for seed-sowing next month.

Fruit Garden.

Strawberries for forcing may be placed in heat in larger numbers now. Start them in a temperature of 50 degs. at night, and when some progress has been made raise the temperature to 55 degs. or a little more, and when the berries are set and thinned raise the temperature to 65 degs. if early Strawberries are required. Strawberries are unlike many fruits which are forced. It is not necessary, except in the case of pushing them on rapidly, to continue increasing the temperature. Though they will not be so early, they will be quite as good if brought on in a low temperature all through their growth. Strawberries in bloom must be helped with the camel-hair brush. A light dusting over with the syringe on a bright morning about 10.30 to 11 a.m. will help to disperse the pollen, and pretty well the same thing will happen with Peaches if syringed when in full bloom. If there comes a dry, hot day, the under glass when Peach-trees are in bloom I have often noticed that the blossoms do not set so well unless the syringe is used. It is interesting to notice different kinds of Pines when a number of trees are growing under the same conditions in one house. The Royal George, as is well known, is one of the best setting and cropping Peaches in existence. It is not so large as some, but it is certain to come right. Dymond, River's Early York, and Gross Mission are good setters. The trees which usually carry the lightest crop under glass are Waterloo, Alexander, and Noblesse, though Waterloo sets well outside on a sunny wall. It is difficult to make young trees under glass moderate their growth. The conclusion I have come to is that the moment it is noticed a tree is making wood of too strong a character, as soon as the leaves fall off the roots; this effectually checks over-luxuriance. Melons now making progress may have a night temperature not under 65 degs., with a comfortable bottom-heat.

Vegetable Garden.

Late sowing generally means late gathering, especially as regards early Peas. When the middle of February is here there is no time to lose. I do not say seeds should be sown so rashly in respect to the condition of the land; but as soon as the surface is dry and the soil works kindly get early crops of all the things which are required as soon as possible. A great deal may be done with hot-beds now. Not an inch of space should be wasted. When frames are used for forcing Sea-kale and Asparagus, as soon as the produce has been cut, turn out the roots, stir up the soil, and add more if required, and till up immediately with another crop, such as early Potatoes, Horn Carrots, or Paris Market Lettuce. Be advised to sow Cauliflowers at this season in heat so a few seeds of Veitch's Autumn Giant, in heat a sowing was made in autumn. By sowing now in heat and helping the plants on as much as the early varieties, the plants will come in useful in August and later, when it hot and dry, the early kinds and Walcheren will be quite useless. This is a very valuable quality in this time of year; no matter how dry the weather will be, the plants will get rough and unusable. The only objection to it

is it sometimes on rich land gets too large. Celery is generally lasting out well this season. There has been no sharp frost to injure it much, as the week's sharp weather was had but scarcely any harm. Early Potatoes may be planted on the early border. I expect there will be more Myatt's and Beauty of Hebron Potatoes than any other planted in small gardens; they are both reliable. E. Hobbart.

Work in the Town Garden.

It is time that seed of Tomatoes was in now. These plants require a long period of growth before producing the first ripe fruit, and though they will stand a good deal of heat in the earlier stages, too much only weakens them, and in any case amateurs seldom get their plants to grow as fast and strong as those who have to make a living out of it. Tomatoes sown in January ought to ripen their first fruits in May, and those started in February in June, but it is not everyone who can do this. The manner in which the culture of Tomatoes has spread during the last few years is really astonishing, and if the total extent of glass devoted to this crop throughout the country could be ascertained it would be found to be almost incredible. I know that the number of specimens of this subject on the subject I am constantly receiving. Even plants for outdoor culture should be raised this month, if possible, for large and strong examples in 6-inch or 7-inch pots, turned out at the end of May, will begin fruiting directly, and the best part of the season be thus benefited by, instead of being lost as when small, late-sown plants are used. There is not much to see or be done in the outdoor garden yet, the only plant that seems to be capable of blooming at this season where there is any smoke about being the Mezeron (Daphne mezereum), which is at present a perfect mass of rosy-lilac blossoms. The Winter or Naked-flowered Jasmine, too, does well in towns, and every garden ought to obtain a specimen or two of both these charming plants. The next thing to bloom will be this beautiful flowering Almond, a free which grows and flowers profusely anywhere. Crocuses and Snowdrops are making a pretty show now; if birds stick the blossoms in a few turns of black cotton just above the rows or patches, securing it to short sticks. In a cold frame or house common Primroses are a mass of bloom, and there are some flowers on the Christmas Roses yet. What a pity it seems that we cannot get Violets to flower, and scarcely to grow, in town gardens! Vines, both indoors and out, should be pruned without delay; those under glass may be started at any time now, though where there is only Crocuses, for example, as a rule allowed to take root. A few Strawberries in pots are very interesting, and, with due care, will produce some welcome fruit; they may be brought into a fairly warm greenhouse at once, the best place being on a high shelf near the glass. Keen's Seedling and Noble are the two best sorts for town gardens but the latter is sadly deficient in flavour. B. C. R.

THE COMINO WEEK'S WORK.

Extracts from a Garden Diary from February 17th to February 24th.

Took up the remainder of the Jerusalem Artichokes; selected the best shaped medium-sized tubers for planting, and placed the others in a store to be ready for use when required. Took up more Rhubarb-roots for forcing in Mushroom-houses. Gave the ground intended for Onions a dressing of soot and forked it in lightly. Sowed Brussels Sprouts in a warm border; a few seeds have also been sown in box under glass as it is important to raise some plants early. Planted Cauliflowers under handlights; also a row in a trench close to front wall of forcing-house. Sowed a box of seeds in warm house. Made up a slight hot-bed for sowing seeds of Celery in frame. Cleared out exhausted Mushroom-beds, and made up new beds for succession. Watered beds in bearing with warm liquid-manure. Sowed Mustard and Cress in boxes two or three times a week as required. Filled up winter Lettuce-beds and planted new beds. Took remaining Peas, and sintered and dug land for next crop. Sowed Peas and Beans for succession. Put sticks to autumn-sown Peas. Sowed seeds of Lockie's Perfection Cucumber. Potted off Tomatoes; shall keep them on stages near the glass in a warm house. Made a new plantation of Sea-kale by planting the thongs or roots cut from the strong crowns when taken up for forcing; they were planted in rows 13 inches apart and 18 inches apart in the rows. The sets were planted in a dibble, just covering the crowns. The cuttings had been laid in slant sand and had begun to form new crowns on the upper ends of the roots. Such roots make strong crowns suitable for forcing in one season. Prepared a piece of ground and drew drills 18 inches apart and sowed Asparagus seeds of the Colossal variety, which, I think, comes into bearing rather earlier than this common variety. Put in cuttings of various things, including a lot of set plants, such as Crotons, Brassicas, Endives, Beignias, and Potatoes. Planted and divided some to increase stock; but a good many of the common sorts are raised from spores. Usually the Ferns and a good many Alliums, Polydiums, &c., come up all over the house from the spores, which are scattered from the plants as they ripen. Several species of Aspidium and others, which are viviparous, are propagated by cuttings of the fronds. Sowed more Tomatoes, including Perfection, Ham Green Favourite, and Glamorgan. Looked over Peaches and Vines in forcing-houses to thin young wood and to down. Thinned Grapes in early house. Gave inside borders a good soaking of warm water. Put in a few more Chrysanthemum-cuttings of late sorts, of which cuttings have been rather scarce. Potted on young Fuchsias. Stirred the soil among beds and borders of spring flowers. Forked up borders chiefly occupied with bulbs. Finished pinning and training Peach-trees on walls. Took up and replanted Box-geraniums in the new greenhouse, and Peas, which, in order to obtain some effect at once, were planted rather thick. Moved more Strawberries to forcing-house. Used camel-hair-pencil among plants in bloom about 11 a.m. Shifted on young Palms into 5-inch pots. Potted off bedding "Geraniums." Divided a lot of Lobelia regina and potted the offsets. Stopped tying and top-dressing the borders in stone. Planted forcing Beans for succession.

* In cold or northern districts the operations referred to under "Garden Work" may be done from ten days to a fortnight later than is here indicated with ground and soil.

GRAFTING A BAD PRACTICE.

The art of grafting is in many respects a great nuisance, although the nurserymen will not be easily persuaded on that point. Trade customs and practices notwithstanding, however, it is pretty clear the practice of grafting everything upon something else does a lot of harm, and in regard to a great many ornamental shrubs is the cause of their being neglected and left in comparative obscurity. In the course of extensive planting of trees and shrubs for some years past I have had many curious experiences, and some absolute failures. A quantity of the Fiery Thorn (*Crataegus Lelanii*) was planted where a fringe of low luscious growth was desired. The following year a plentiful crop of Quince suckers appeared, and it was simply a case of the survival of the fittest, which, of course, was the strongest, so the Quinces were transplanted elsewhere. This shrub can be raised in any quantity from seed, and I have since made other plantations of seedlings with the best results. The little single and double Plume and Almonds, some of the prettiest shrubs of spring-time, are among the early failures so grafted plants. If happily they are established on their own roots they are not likely to disappear. Of course, the nurseryman says we should

WATCH FOR AND REMOVE the suckers as they come, but when one has all the lovely flowering shrubs, this is not a simple matter. It is an endless job. It is absurd to suppose that this grafting either adds to the vigour or in any way assists the plant to make strong and healthy growth. The very opposite generally happens. It is crippled by an unhappy alliance or union with something else, never shows its true character, but ultimately dies. The moral is a very simple one. Avoid grafted shrubs. It will need close observation to see that they do not come in unawares. Last year a very interesting Bramble, with large Hawthorn-like leaves, named *Rubus crataegifolius*, came to me and was duly planted. There were three plants, but they are all dead, victims of grafting. The last one, which had made some growth, I had taken up recently to remove elsewhere, but its stock had died clean away, leaving a rootless branch. The new

RED BROOM (*Genista Andreana*) is now being generally distributed, but most of the plants I see are grafted, and that means future trouble and many deaths. This shrub will strike from cuttings, and therefore it can be had upon its own roots, and will begin to flower before it is a yard high. Those who plant specimen Conifers of the choicer kinds should see that they are not grafted, for the practice is a special abomination with regard to these. The height of absurdity was reached among Conifers by grafting the Deciduar upon the Larch—an evergreen upon a summer leafing tree! The only recommendation that grafting has is it is an expeditious method of raising stock, but it has also and truly been called fraudulent, for it is a species of fraud to distribute plants upon foster roots that linger for a time only to be choked to death in the unequal contest between root and branch. What is true of ornamental shrubs, to which these notes have special reference, will also apply to standard fruits, and it is now clearly proved that our

BEST APPLES will grow as well and fruit so finely upon their own roots as upon those of the Crab or any other stock. The Medlar is a charming tree in leaf, flower, and fruit, but it is often crippled by grafting. I have just chopped down three standard trees that have been six years planted and have hardly made any growth. Certainly the diameter of the head of the tree has not increased 1 foot in the six years. The reason is that the Medlar is grafted on a Pear-stem, and the Pear is on the roots of something else. Other Medlars planted at the same time have made nice trees, but they are grafted on the Hawthorn. Inquiries in many directions have failed to find out anyone who has the Medlar on its own roots, and yet it is a native tree and knows no grafting in its wild state.

A. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings, if made in the best manner and will appear in due course in GARDENING ILLUSTRATED.

TREES AND SHRUBS.

CHOICE FLOWERING PLANTS.

HIMALAYAN HEATHER (CASSIOPE FASTIGIATA).
CASSIOPE is a limited genus of ericaceous plants generally grown in gardens under the name of *Andromeda*, but now separated from that genus, which contains only one species (*A. polifolia*), a native of our own moors. They are extremely pretty plants, and should find a place in all collections of hardy flowers, the chief requisites to their successful cultivation being peaty soil well drained, as they are all extremely impatient of stagnant moisture about their roots and absolute shade from the midday sun. The best plan is to raise small mounds of peat, and plant them on the top, taking care that they do not wait for water both at the roots and overhead. They are increased by division, rooting freely when pegged down. *C. fastigiata* (here figured) is decidedly the handsomest of this small group of plants, few of which are in

Himalayan Heather (*Cassiope fastigiata*).

cultivation. As an alpine species *C. fastigiata* ranks among the best plants we possess; it may be grown without much trouble in company with the more common *C. tetragona*, a species much inferior, though oftener met with. Its range of altitude is pretty extensive. Sir J. D. Hooker, in his "Himalayan Journals," says: "I prepared to camp on the mountain-top, a broad bare flat, elevated 13,080 feet, and fringed by a copse of Rose, Barberry, and alpine *Rhododendrons*. The Himalayan Heather (*C. fastigiata*) grew abundantly here, affording us good fuel."

5486.—"Cardinal" Willows.—The distance apart at which these should be planted can best be decided by the area it is intended to plant. For a speedy effect they must be thickly planted at from 4 ft. to 6 ft. apart. They will soon, however, require thinning if placed at this distance. The habit of growth of this Willow is somewhat erect and, after the manner of the Lombardy Poplar, but possibly with age it may become more spreading. The Yellow-barked Willow

(*Salix vitellina*), of which the Cardinal Willow is said to be but a variety, makes a spreading tree when large. I have not, however, seen any of the Cardinal Willow more than 16 feet or 18 feet high; but it is comparatively new, as it was only sent out in 1878-79, and some years then elapsed before its high merits were recognized so an ornamental tree. It is not the rule to recommend particular firms in these pages, but the nurseries to which I alluded in my article were those of Mr. Anthony Waterer, Messrs Jackman, and Mr. W. Slocock, all of which are at Woking, and in all of them I saw quantities of this special Willow on the occasion mentioned.—A. H.

5506.—Hedge for a wind guard.—In this case certainly the Privet would be a very poor and ineffectual thing, because a hedge to give shelter must have some degree of height, and a high Privet-hedge would be in danger of partial or complete prostration. It is better to wait a little longer for the growth of something else if a hedge that will answer the purpose required of it is ultimately secured. A good hedge gives as much shelter so a wall. I was recently standing behind a line of natural unclipped Hollies during a tremendous gale, and yet could not feel the slightest force of the wind. I can hardly recommend Holly to "Faber," however; it would be too slow. Perhaps he would try Lawson's Cypress (*Cupressus Lawsoniana*). This grows very rapidly, bears any amount of cutting, and I have seen perfect wind-breaks 16 feet high made with it. It is now plentiful and cheap in the large nurseries. The Beech makes an excellent hedge, and there are some magnificent hedges of it, enclosing and sheltering large portions of the kitchen garden at Livermore Park, Bury St. Edmunds. The common Yew of course is first-rate, but comes rather more expensive. I recall to mind another large hedge composed of Cherry Plum and Hawthorn, the first-named being a rapid grower whilst a mixture of Quick gave it greater density. Almost everyone thinks first of Privet, but I would place it last always, and always find things for a hedge for ornament or use without calling upon it.—A. H.

5499.—Propagating variegated Holly.—The variegated Holly may be increased from cuttings if you take shoots of the current year's growth about the end of July, and insert them in sandy soil under a glass-light where they are shaded one half the day. Only the young wood will make roots, and this must be shaded from bright sun at first, and kept close until late in the following spring. You had better make up your mind to allow them to remain two years before you move them. In nurseries variegated Hollies are increased by grafting, but that is tiresome work for an amateur.—J. C. C.

5488.—*Hydrangea paniculata*.—Cuttings of the young shoots will strike under a hand-light in summer, and cuttings of the ripe wood will root in a shady border if put in as soon as the leaves fall, and the plants are easily propagated from layers.—E. H.

—These may be easily struck from cuttings of the soft wood—at any rate, I once struck a good batch. The shoots were taken when young in spring after they had made about 2 inches of growth. They were cut off with just a small heel of the old firm wood attached, prepared and inserted in the usual way, and placed under a handlight in a propagating house. If "Mr. Selden" follows the usual plan of cutting the plants down annually he will have no difficulty in getting suitable cuttings whether the plants are out-of-doors or in

I should think that layering would also answer, and this is easily performed with plants in the open ground.—A. H.

WHITE JEW'S MALLOW (RHODOTYPOS KERRIOIDES).

This is a beautiful deciduous shrub from Japan, with a growth and foliage recalling the familiar old Jew's Mallow on cottage walls, but with

Flower of White Jew's Mallow (*Rhodotypos kerrioides*.)

white flowers resembling single Roses (see cut). It is of slender growth, but makes a dense bush when well grown, and is usually 5 feet or 6 feet high, though against a wall it reaches a height of 10 feet or 12 feet. It flowers in May, and keeps in bloom a considerable time. B.

5493.—*Ozothamnus rosmarinifolius*.—Certainly this might be grown as a pot plant in a cool greenhouse, and treated well it would doubtless soon become a very pretty and most ornamental thing. It might be stood outside during the heat period of the year. As regards its adaptability for out-of-doors in the North of Scotland if the place is a favoured one a trial might be made with it, choosing a sunny as well as a sheltered spot.—A. H.

5471.—*Shrubs under trees*.—Very few shrubs will grow well under the Horse-Chestnut; the most likely things to grow would be Butcher's Broom, Aucuba, Yucca, St. Julian's Wort, Green Ivy, including the Arborvitae or Tree Ivy, and hardy Ferns. The Lime-trees being less dense of foliage, Laurels, Hollies, Yews, Boxes, and Evergreen Barberries will succeed. It will be necessary to soil some fresh soil and dig up the ground before planting anything.—E. H.

5411.—*Treatment of Euonymus*.—It is not the salt in the water and atmosphere which makes the *Euonymus* grow so freely round the coast. It is a mild, genial climate and the absence of frost. Salt and water applied artificially will not benefit the plants.—E. H.

5520.—*Deutzia gracilis*.—Your plant of this pretty shrub will not flower to any great extent unless it made some healthy shoots after the bloom of last season was secured. It blooms upon the wood of the previous season, and although it may be pushing out growth again, you alone can judge from the above whether it will be worth house room. The temperature you name is suitable, as it will increase shortly.—F. U.

5469.—*Propagating Gum Cistus*.—These are readily increased by cuttings of healthy wood taken off as soon as the points commence new growth. About the early part of April is a good time. Three inches long, and inserted in a compost of sand, leaf-soil, and peat, well syringed and kept close until rooted. A hand-glass over them in an ordinary greenhouse temperature will suffice, but a slight bottom-heat affords material assistance.—F. U.

5601.—*Ophiopogon Jaburan variegatum*.—This is a Japanese plant, and is nearly, if not quite, hardy. It will live on a well-drained rockery, and it is also a rather pretty room or window plant, producing slender spikes of blue flowers in spring or early summer. It is not difficult to cultivate, but if grown in rich soil, to a certain extent the plant loses its variegation. It will grow very well in the shade in summer with Ferns and foliage plants in a cool-house or in a heated greenhouse.—E. H.

FRUIT.

FERMENTING MATERIAL FOR OUTSIDE VINE-BORDERS.

At one time fermenting material was more largely used than it now is for covering the outside borders in which early forced Vines were grown. Not that its discontinuance has improved the quality of early Grapes, as with all our boasted advancement in fruit culture, early Grapes are not grown any better, or so good as twenty years ago; in fact, really good Grapes at the earliest shows are far more of a rarity than they used to be. The variety principally relied upon for forcing (at least for early work) is the Black Hamburgh, that will put up with almost any abuse and yet come out passable in the end. There is, however, a limit to its enduring powers, and the production of really good early Grapes of this variety is something to be proud of. Often, however, they are poor in colour, and instead of the bunches being compact, with the berries of a nice black colour, also carrying a good bloom, they are the very opposite and also marred by slanking. This latter is an evil much on the increase in early forced Vines, especially in the variety above noted. There is nothing in the cultivation of Vines more annoying than to see the bunches decrease in size. Generally this is the result of defective root-action. It has become very much the practice to allow the borders to remain uncovered until forcing commences, the belief being that when the borders are covered the Vines do not receive that thorough rest they should have. To a certain extent this is not borne out by facts. To cover the border up so that frost cannot reach the surface may be an evil, but not so protection from wet or snow, which may easily be secured by using shutters or sheets of corrugated zinc. I use both, and also spare lights. Borders covered with fermenting material when forcing commences are just in the condition to derive marked benefit. It is those borders which are covered with a layer of manure early in the season without further sheltering that are in danger of being spoiled by mistaken kindness. A heavy fall of snow will often penetrate deeply, and the soil about the roots will then be cold and damp; consequently, if fermenting material is now applied, these borders cannot be expected to derive such marked benefit as others which have been covered with a few dry leaves and boards.

COVERING VINE-BORDERS with fermenting material without using boards is not the best means of treating them. In the first place, a greater depth of material is needed, and even with this addition it does not retain the heat so long as a much less bulk if this be covered. For covering outside Vine borders I have great faith in the bulk being tree leaves, Oak or Beech for preference, as being of a hard nature they heat the more readily, and also retain the warmth for a lengthened period. I use Beech leaves, and they maintain the heat well. Last year early in January I covered the border of a large Hamburgh house with quite three parts leaves to one of litter, putting it on to the depth of 2 feet near the front wall, and the heat was retained well on to the end of April. But the above would not have been the case had not the border been further covered with proper Vine-border boards. In the above case the roots worked well, and the Vines ripened off a fine crop of early Grapes, the berries and bunches being of a large size, as they always are on the Vines in this house, although they must be quite fifty years old. I firmly believe that a gentle hot-bed is of great assistance for covering the roots of early forced Vines—that is, when the border is partially inside and out. With this assistance I think Vines also break more strongly and evenly. The reason no doubt why the system is not practised so much as its merits deserve is the labour attending it. By using the greater part of good leaves with a portion of stable-litter, sufficient heat will be maintained quite long enough for the Vines to benefit by it. A.

5479.—*Blood as manure for Vines*.—Blood is a powerful stimulant, and it should be used in its fresh state with caution, and as an experiment at first by those who have had no experience with it. In its fresh state, when it will mix with water, dilute it with six times its

weight of water, and apply it liberally to both inside and outside borders during spring; say, twice during the season—first, when the Vines have just burst into leaf, and again after the Grapes are thinned. If the blood has become congealed it should be used in the form of a compost, mixed with wood-ashes or burnt or charcoal earth, and in this condition it is difficult to give directions as regards quantities. Something depends upon the condition of the border as regards drainage, &c., but it is better to err on the right side than do too much.—E. H.

PEAR "PITMASTON DUCHESS."

This is a popular though not a high-class Pear. There is no connection between it and Duchesse d'Angoulême, which is a coarse, gritty French Pear, later in ripening, valuable for market, but nearly always second-rate in our climate. It bears a much stronger resemblance to Marie Louise in all but flavour, but grows much larger, and medium-sized fruit can also be distinguished readily enough, owing to there always being a patch of russet near the footstalk. Naturally, much the finest fruits are usually obtained from well-grown wall trees, the fruit also being more pyriform and clear in colour than is the case when the trees are grown in the open. Wherever the fruit is grown the same failing in the quality prevails, an unpleasant acidity generally offending the palate of all who appreciate a really good buttery Pear. There is yet another failing, and that is the thinness and sensitiveness of its skin. The fruit grown against walls, if carefully handled and properly packed when sent to a distance, is beautifully clear, but that obtained from pyramids and bushes is very apt to present a much-scratched, bruised appearance when fully ripe. This I attribute to wind-waving and contact, it may be, with leaves and branches; but it is so very marked and almost inevitable, that had I any to market I would send them before they were fully ripe. The season of this productive Pear is said to extend from October to the end of November, but, as a rule, the fruit will not keep so long as that, the middle of November frequently seeing the last of it. Quite young wall-trees produce fruit, while those six years old and upwards yield grand crops, which, if freely thinned, as they must be if samples 1 lb. or little less in weight are desired, pay remarkably well. Cordons with one or several branches also produce exceptionally good crops of fruit, and no collection of wall-trees may, therefore, be said to be complete unless it comprises one or more specimens of Pitmaston Duchess. This remark applies with still greater force to pyramid and other low standard trees, but these, for reasons already given,

Pear "Pitmaston Duchess."

ought always to be located in a somewhat sheltered position. If a fairly healthy young tree is planted on moderately good ground, the preference being given to a site where the sub-soil is of a gravelly nature, it will, without much further trouble, quickly develop into a bush naturally grown pyramid, and produce several bushels of fine fruit whenever the season is not dead against fruit-trees generally. G.

5520.—An old orchard.—Seeing that you have gone so far with the expense of trying to renovate the old trees in the orchard, you cannot do better than work out your own ideas, and wait the result. Were the trees mine, I should tremble for their safety next summer, seeing that you have cut asunder all the roots to within 2 feet of the hole. I think you would have done better if you had grubbed out all the trees, and devoted the coming summer to cleaning the land from weeds, and planted the ground in the autumn with young trees. Why run the risk of using paraffin with the lime when the latter alone will destroy the Moss?—J. C. C.

5523.—Heating a Vinery.—I think you have been very patient, and I am only surprised that you have not sought for advice earlier. If you are not forcing your Vines in either house quite two thirds of the fuel you are now consuming has been burnt to waste. For a cold vinery a temperature of 45 degs. by day with fire-heat is quite sufficient, and 5 degs. less at night will keep everything safe. As to a temperature of 100 degs. by day with the ventilators open doing no harm it is perfectly absurd. Your case is, however, only one amongst many in which fuel is consumed in waste in gardens. Hundreds of tons in as many small gardens are wasted every year, and the plants the heat is intended to benefit are weakened if not spoiled by it. I have known many instances where the cost of fuel unnecessarily consumed by men who do not understand their business would have gone a good way towards finding the increased pay that a more skillful man would require.—J. C. C.

5521.—A small vinery.—Black Alicante is the easiest of all Grapes to grow. This ripens well and would be ready for sale about Christmas. Gros Colmar is perhaps a trifle better Grape for sale, but is not nearly so easy to grow, and requires much more fire-heat to finish it well. If the former variety is chosen the Vines should be started, say, the first week in March, at a temperature of 50 degs. at night, and about 65 degs. by day. Let the Vines have the benefit of the fire-heat until the berries are thinned, when, if the weather is mild, they will do well without artificial heat. But in the case of cold nights it is wise to light the fire, even if only for a few hours. To allow the temperature to fall below 60 degs., for instance, at night is injurious to the crop. During the dull and often damp days of autumn artificial heat will be necessary to dispel damp from the vinery, or the berries will decay. One-year-old canes are the best for planting. Cut these down to within two eyes of their bases early in March, to induce the rods to grow stronger the first year. Although two eyes are left on the canes, it is only intended that one shall remain; the other is a safeguard in case of accident. A space of 3 feet should be left between each Vine. Nothing is gained by crowding them.—S. P.

5515.—Pear "Louise Bonne of Jersey."—This is a case of canker, owing to the soil being unsuited to this variety. I should be surprised to hear that the soil in which the tree is growing is not of a heavy, retentive nature. Soil of this texture is generally quite unsuited to the growth of this Pear. Lift the tree at once, removing the soil to a depth of 15 inches and 3 feet wide, replacing it with road-side refuse, old potting soil, decayed vegetable refuse, and wood-ashes, first thoroughly breaking up the subsoil, to allow of a quick percolation of water from heavy rains. Plant the tree on the surface, making up a slight mound around it. In time this will settle to the natural level of the ground. Mulch the surface with 3 inches of partly-decayed stable-manure, or decayed vegetable refuse. Pare off the cankered parts of the bark, and rub quicklime into the parts affected.—S. P.

5346.—Treatment of Chinese Primulas.—The seed of Chinese Primulas may be sown at the end of May or early in June, and again at the end of July for a succession. You will require a warm frame for the seed. Fill a 5-inch pot or shallow pan with well-prepared soil, light, and crock the pot or pan well to assure perfect drainage, without which it is hopeless to expect good results. Water the soil through a fine rose ~~watered pot and cover~~ with the seed thinly, and carefully covering with fine soil. Place a glass over it to promote quick

germination, and when the seedlings appear prick them off into other pans filled with the same compost, and from there pot them on. A good light loamy soil suits them best. They require a warm temperature at all times, and to be kept near the light; otherwise the growth gets weakly and drawn.—E. F.

5427.—Peach dropping its buds.—If the tree has not dropped its buds before it is quite safe to conclude that something is wrong in the treatment. If the foliage was much injured by red-spider last summer—a not unusual occurrence in such a hot dry season—that would be sufficient to account for your present trouble. Dryness at the roots since the buds have fallen would also account for it. If your tree has not had its branches dressed with some strong insecticide which has injured the buds while they were dormant, you must look to one of the first two mentioned causes to decide your inquiry.—J. C. C.

5487.—Artificial manure for Vines.—I have used a good many artificial manures for Vines, and without deprecating any I can say after two seasons' use I should recommend the Patent Silicate Manure to be applied twice during the growing season; first, as soon as the Grapes are thinned give a liberal dressing, and again when the stoning is nearly finished.—E. H.

FERNS.

TREE FERNS FOR COOL-HOUSES OR FERNERRIES.

DICKSONIA ANTARCTICA.—As far as general utility and hardiness are concerned, there is probably no Tree Fern to equal or surpass

The Tasmanian Tree Fern (*Dicksonia antarctica*).

Dicksonia antarctica (see illustration). It is useful from quite a small plant, when only emerging out of the seedling stage, up to the grand specimens of imported growth with their noble-looking stems. They are particularly useful whilst in about 6-inch pots; when well established therein they can be used for decoration with good effect, making first-rate vase plants. Plenty of water, of course, must be given them; this is only a natural sequence when dealing with this and other Tree Ferns in a thriving state. The style of growth of this Fern whilst still in its earlier stages of development is very pleasing. It is then of a more spreading character than later on, for as it attains height and rigour a more erect growth is assumed. When young plants begin to show signs of forming a stem their growth in this direction can be considerably hastened by working a ring of Sphagnum Moss around the stem at the base. This progress can and should afterwards be followed up as the roots take hold of it, adding at the base, so as to increase the diameter, and also upwards amongst the stems of the fronds to add to the height. By this means I have been enabled to increase the height considerably as much as 1 foot in three years when once a good stem was made. Unless this system of increas-

ing the height of the stems is understood, it may not appear to be altogether logical. That it is so in fact I have myself proved conclusively. To facilitate the process, the old fronds as they fade and are cut off should be left about a couple or 3 inches longer than is usually done; this affords a means of support to the Moss, which can also be worked up amongst the fresh green fronds as well. Then, by keeping it all moist, not only by the syringe, but also with the watering-pot (with a rose on), pouring it over the crown, fresh roots will soon push out and take entire hold of the Moss. This process of mossing up is entirely different from that of mossing up an old stem, an imported one, for instance; it is not often in this latter case that sufficient roots will push forth to hold up the Moss. In the former the roots in process of time envelop all the Moss, making a stout and massive-looking stem.

SHADING.—This is not necessary save in small houses. With too much or constant shade, the fronds are not nearly so enduring, being at the same time liable to what I take to be a disease concurrent with shade and too much moisture. The fronds assume a brownish appearance somewhat similar to what one might attribute to red-spider, but with no evidence of insects at all. This will extend from the tips of the pinnae and in due course make the fronds quite unsightly. In one house where several plants of Tree Ferns were grown, this failing used to occur every summer season, the house being heavily shaded and kept very moist. The shading was at last dispensed with entirely, and the

growth afterwards was as healthy as possible, this being, I think quite a conclusive proof of the source of the complaint. In the way of insect pests the black thrips is about the most troublesome, attacking the lower fronds mainly, and if it is not detected, it will soon disfigure them. Where the syringe does not frequently reach the fronds on the lower sides there will be a congenial breeding place for this insect. Brown-scale is, next to thrips, the most troublesome, and if not stopped in time will quite spoil the fronds. Both insects may, however, be kept under by ordinary methods, the former by hand-picking and fumigation, the latter by hand-picking and light cleaning with a soft brush and a weak insecticide. When plants are very much pot-bound and no further shift is desirable, a narrow margin of fibrous peat and Moss may be built up around the rims of the pots. The roots will soon lay hold of this, and provision will be made for more effectual watering. This is quite necessary in the case of plants with large heads, for even where a fair amount of room was originally allowed for watering, I have noted that in due course the roots and soil would be almost level with the tops of the pots. Weak firmyard manure-water, or the Canada with guano and a little soft soil greatly helps such plants. When

in this condition, it is hardly possible to give them too much water, two or three times a day being none too often to water them in hot weather. I once had a plant in a No. 1 pot which in course of time cracked the pot by reason of the mass of roots, the growth always being extremely vigorous. When the young fronds appear, and that in quantity together—which in the usual way in the case of hasty plants—it is an indication that even closer attention must be given them for watering. With a ring of from twenty to thirty young fronds growing quickly, the resources of any one plant must be severely taxed, and a check at such times means the crippling of the fronds, the points not developing in such a satisfactory manner. Next to *Dicksonia antarctica*, I consider

CYATHEA DEALBATA is one of the most useful and serviceable of Tree-Ferns. It may not be quite so hardy, but as regards its beauty it even surpasses, in my opinion, the first-named. It is well termed the Silver Tree Fern by reason of the glaucous, silvery shading of the lower sides of the fronds. The pale green of the upper sides of the same also makes it quite distinct. The stems are not usually so stout either, except when planted out. From a small plant upwards this *Cyathea* is extremely handsome, and worthy of every attention. Compared with the foregoing it is also much scarcer, but it should not be. In my opinion it should have a more peaty soil than the *Dicksonia*, only a little turfy loam being used, whilst the other may have half and half. Although it is a strong grower when in a healthy state, it does not make such a quantity of roots as in the other case; this can be readily attributed to the comparatively lesser number of fronds usually borne by a plant of relative size. I should add as regards the soil that I would use a little Sphagnum Moss with it, chopped up fine. This will not only encourage fresh root action, but retain moisture as well. *Cyathea dealbata* is more sensitive even than *Dicksonia antarctica* to drought at the roots. If it remains dry for but a short time and the points of the pinnae commence to curl, it will be impossible to restore them to their normal condition. Should such a misfortune arise in either case shading for a time must be used, and that rather heavily, whilst the plant is thoroughly moistened all over and kept so for some considerable time. It is a rare thing for *Cyathea dealbata* to be troubled with insects; at least this has been my experience, and I have grown both from small plants to specimens for several years. Anything in the way of potting may very well be attended to now, as the growth will soon commence. Where shifted into larger pots or tubs it is hardly ever possible to do much to the old ball when it is a mass of roots, but it will not hurt to cut away a portion at the base, so as to allow of sufficient depth in the new pot or tub, with a little room at least for a top-dressing. Firm potting is, I consider, quite essential, otherwise it will not be possible to retain the old ball in a moist condition. My practice has been to pot firmly, but not to give a large shift. When there is any suspicion of a newly-potted plant being too dry at the centre, a few holes 6 inches or more in depth should be made in the old ball, then when watered the desired effect will be obtained. I would only advise planting out in any case when there is an abundance of head-room; it means more luxuriant growth, imparting more shade to things underneath, if any be grown there. True, such a spot would be congenial to such as *Todea* and *Hymenophyllum* where grown in quantity. Plants in an unhealthy state should be reduced so as to go into a pot of the same size or a smaller one according to the case. G.

5372.—**Ferns for a case.**—“A. D. C.” omits to give the size of the Fern-case, and on this, partly, the selection must rest. If it be about 18 inches in height, the following Ferns may be grown in it on the understanding that frost is kept out as they are of the greenhouse section: *Adiantum cuneatum*, the prettiest of the Maiden-hairs, and *Adiantum Farleyense*, which is fairly hardy; *Pteris cretica*, *P. serrulata*, and *P. tremula* Smithiana, all excellent Ferns for a room; *Asplenium bulbiferum*, a handsome Fern, which produces fine specimens on its fronds; *Phlebodium aureum*,

and *Asplenium flaccidum*, also a strong-growing plant. *Lygodium scandens* (the Climbing Fern), might be tried, but it is not so hardy as those above, though it is so lovely and unique in its growth that it is well worth a trial. The soil for these Ferns should consist of loam, leaf-mould, and peat with plenty of silver-sand, and the tray in which they grow must be well drained, for stagnant water will induce mildew, which is fatal in its effects. If the case has no holes to allow of the passage of water there should be made before the plants are put in, and the bottom of the tray should contain a layer of corks, cinders, and bits of charcoal, covered by a thin layer of Moss, then rough bits of peat, pulled to pieces with the hand, and the finer part of the compost on the top. The whole may be soaked before inserting the Ferns with boiling water to destroy all germs of animal or plant life, and allowed to become fairly cool before the plants (which should be turned out of small pots) are put in. It is better to begin with a few good kinds, and add others as experience is gained. The surface of the soil may be covered with *Selaginella* or *Tradescantia discolor*. To make a variety in tint one or two good *Begonias* of the Rex type may be introduced, *Louise Clowen* being one of the best for this purpose, with dark-crimson and maroon leaves. Ferns and these *Begonias* both enjoy a still, damp atmosphere without draught, yet they must have ventilation at the top to let off the steam, which will otherwise fall again and set up mildew in the case. If there be no ventilation in the movable case a small opening should be made at the top to be closed while gas is burning, but open for a few hours daily in a pure atmosphere. Tepid water should be given whenever the glass shows no mist when put in sunshine: enough to run through the drainage.—f. L. R.

5452.—**Adiantum Capillum-veneris.**—Two parts fibrous peat, one part fibry loam, one part leaf-mould, not too much decayed, a small portion old lime rubble, and sharp silver-sand, in proportion to the texture of the loam—light or heavy. Ram the soil into the pots quite firm, as upon this much depends the manner in which growth is made. Abundance of water is required when the plants are growing freely, with occasional waterings of weak liquid-manure. Ferns enjoy this stimulant much more than what many persons imagine.—S. P.

5482.—**Fern compost.**—There is no better compost for the Ferns mentioned and other ordinary descriptions than a mixture of two parts of the best (fibrous) loam procurable, with one part each of peat and leaf-mould, and half a pint of sand. If peat is not easily procurable it may be omitted, using rather more leaf-mould instead, or an equal quantity of fresh sifted Cocoa-nut fibre. Such Ferns may and are often grown capably in almost pure loam, this being of a light and sandy, peaty, or “silky” nature, and only a little leaf-mould being added. The heavier the loam the more leaf-mould, &c., should be added; the lighter it is the less is needed.—B. C. R.

ORCHIDS.

SOPHRONITIS GRANDIFLORA.

I AM asked by “G. T. B.” to say a few words about the management of this beautiful little plant, which I do willingly, as it is a particular favourite of mine, and I have seen some very good varieties of it of late years. This Orchid was first sent to the celebrated Messrs. Loddiges, of Hackney, some time early in the present century, or at least in the first half of it, and it flowered with them for the first time in this country in 1841, and I suppose it is one of the *Sophronitis* entered in their catalogue, published in 1839, numbered 470 to 473, without any specific name. It is a plant which grows at considerable elevations on the Organ Mountains in Brazil, and it was some time before the right method was adopted for its successful cultivation. I remember well when I first went into the Orchid-houses, now many years ago, that this plant was always treated to the warmth of the Cattleya-house, and this structure in those days was a different place as regards the temperature than it is now, and we used to succeed in flowering it fairly well; but, of course, it neither grew nor

blossomed so well as it does now since we have learned to keep the plants hung up in the more genial atmosphere of the *Odontoglossum*-house. There are one or two distinct coloured varieties of this Orchid, which also differ in their hulse and leaves. Some of these have received distinct names, of which *S. militaris* I have thought upon several occasions to be entitled to specific rank, but have failed to establish it on any fixed grounds, so have been compelled to put it with *grandiflora* again. The variety *rosea* is another very pretty form, having flowers of a good round form, giving a nice change of colour from the bright shade of the normal plant, but it is not near so effective. *S. purpurea* is another variety, but it differs considerably in colour, being of a bright rich carmine-purple. *S. violacea* is yet another form, having flowers of a distinct violet hue, which is a valuable acquisition, but they all come under the designation of *S. grandiflora*. This *Sophronitis* thrives best in a hanging-pan or shallow earthenware basket, and this receptacle may be filled with drainage, so as to leave but little space for soil about the roots. In this respect, I think so many make a great mistake, but it likes the little that it does have made nice and firm and solid, using good brown peat-fibre and Sphagnum Moss in about equal proportions. Some of my acquaintances object to the use of the last-named material, but the more I know of Orchids the more I am convinced of its thorough usefulness, and many Orchids have I seen growing in nearly all Sphagnum where I was taught to believe the least bit of it with the peat-fibre would be death to the roots; but be not afraid, my friend, you may use it without the least hesitation in the culture of this plant. Give it abundance of water in the summer season, and during winter do not let it get dry, and keep it hanging up in the front of the *Odontoglossum*-house, in a sunny, light position, with a free circulation of air.

MATT. BRAMBLE.

ONCIDIUM TIGRINUM.

This plant I am asked to enlarge upon by “Jos. Headley,” who sends it under the name *O. Barkeri*, but I do not acknowledge this name, although it was given to it by Lindley after Mr. Barker, of Birmingham, its first cultivator; but he found that it was the same plant as that described by La Lavi under the above name. Neither do I agree with those who would make that fine Orchid called *splendidum* a variety of this *Oncidium*, for, in my opinion, no two plants can be more distinct. However, to confine my remarks to *O. tigrinum*, which is a plant possessed with a strong odour of *Violeta*, and I do not appreciate the name given it by the natives of Mexico, or the Spaniards of that district, who call it “The Flower of the Dead.” A plant which I had growing in my dwelling-house for several years, always used to flower at the new year, but last season being so hot and dry, the plant got neglected and died, so that I did not have the exquisite pleasure of its flowers this season. It makes large hulse, which are slightly compressed at the sides, and upon the top it bears a pair of thin linear oblong leaves which are of a bright green, and from 6 inches to 1 foot in length. The spikes are erect, some 2 feet or 3 feet in length, branched, and bearing many flowers, which, in some instances, measure 3 inches across. These have small sepals, and petals of a bright yellow, blotched with dark brown, and the lip a clear, bright yellow, giving off a delicious odour of *Violeta*. In a superb variety which I had sent me last year from Croydon, the markings being quite black, and the lip of a very deep and rich yellow. I wonder if I shall get it sent again? It is certainly the finest variety I ever saw of this plant. It remains in full floral beauty for a long time, and it retains the fragrance to the last. This is a plant which thrives best when grown in a hanging-basket, well drained, using for soil good brown peat fibre mixed with chopped Sphagnum Moss. It may be accommodated in the cool-house during the whole season, but in the autumn it may be kept somewhat warmer, and it hastens the spikes during the summer season. The plant requires an abundance of water, but it may be kept nearly dry for a short time when the growths are formed.

ILLINOIS AT
URBANA-CHAMPAIGN

ROSES.

YELLOW ROSES.

If there is one colour among Roses more popular than another it is the deep golden-yellow found in such varieties as *Maréchal Niel*, *Perle des Jardins*, *Harrisoni* and others. *Rosa Harrisoni* (here figured), one of the Austrian Briers, was introduced from America by Mr. Harrison in 1830, and is still one of our most popular yellow Roses for garden decoration. As shown in the engraving, it is far more double and globular than the *Persian Yellow*, another very old favourite introduced in 1838.

HARRISONI is a beautiful golden-yellow, but the growth is not so vigorous nor the flowers so deep in colour as in the case of the *Persian Yellow*. I have more than once known the two varieties confused, but when seen together they are quite distinct. These two varieties are amongst the earliest flowering Roses we have, and I have a vivid recollection of how grand they were in this neighbourhood last spring. They are good growers, hardy, and almost certain bloomers. The chief point is to thin out all weakly growths, and so encourage the more vigorous shoots. If these are bent down slightly they will almost invariably bloom throughout their whole length. By bending them down slightly after pruning a more even

only necessary pruning will be the removal of frost-bitten wood.

FORTUNE'S YELLOW (syn., *Beauty of Glazenwood*) is another beautiful semi-double variety that deserves much more extensive cultivation. It is said to have been discovered by Robert Fortune in a rich mandarin's garden at Ningpo, and was introduced to this country by him in 1845. Like the *Banksians*, it does best in a warm and rather dry situation, and, like them, requires careful summer pruning. It is only semi-double and varies much in its colour, sometimes being a pure orange-yellow, and at other times striped and flaked with carmine in very uncertain quantities. The yellow Abyssinian Rose *Eca* is also very pretty. This was introduced by Messrs. W. Paul and Son about 1883; it is small and very pale-yellow in colour.

CLOTH OF GOLD (or *Chromatella*) was sent out in 1843, and was somewhat extensively grown until eclipsed by *Maréchal Niel*. It is a very vigorous grower, and too tender to thrive satisfactorily unless in a warm and very sheltered wall. The blooms are large, double, perfect in form, and of a deep sulphur-yellow with darker centre, but unfortunately it is a difficult variety to grow on account of its extreme tenderness. I have only once been fortunate enough to see it growing well and that was in a Rose garden completely sheltered by specimen shrubs. Being so tender, it rarely

Small, perfect in shape while young, and a good Rose to last, this variety is undoubtedly one of the best climbers for a south wall or under glass. In the latter position I have secured from 500 to 700 blooms from a single plant, and have found it equally as certain as well-grown specimens of *Maréchal Niel*. *Mme. Carnot*, a seedling from W. A. Richardson, is somewhat similar, and also a grand variety.

L'IDéal, of similar habit, is one of the most distinct and attractive Roses we have. Not very full, but of good shape when young; it is decidedly one of the six sweetest-scented Roses grown. Its colour is also very variable, being metallic-red and yellow, splashed and tinted with a golden and coppery-yellow.

DUCHESS D'AUERSTADT.—The flowers of this are pure yellow when young, but partake of a nanken shade as they open. They are large and full, but not of so good shape as those of *Henriette de Beauveau*, a bright clear yellow, very free blooming and sweet-scented.

BELLE LYONNAISE is a pure canary-yellow of the *Gloire de Dijon* type, but not quite so hardy.

REVE D'OR is a typical Yellow Rose, almost evergreen, and of extraordinary vigor.

MME. PALAOT is too well known to need more said of it than that from 1880 to the present time it has been the best of its colour.

ISABELLA SPRUNT, a fixed sport from *Safrano*, is a pure canary-yellow of hardy constitution, very free, and a good button-hole Rose.

JEAN PERNET, a sport from *Devoniensis*, is also exceedingly pretty, but, like its foster parent, it is not sufficiently reliable. Perhaps the best pure yellow Rose among the dwarfier growing Teas and Noisettes is

MADIE VAN HOUTTE. Some of my readers may question my designation of this grand variety as a pure yellow on account of its being frequently tinged with deep rose, especially towards the edges of its petals. But these are merely sun tints, and may be found more or less in many other varieties—*Niphotos*, for example. *Marie van Houtte* is a most excellent grower, hardy, and certain to produce several crops of good flowers during each season.

SENSÉE is of different shade, having a deeper yellow for ground, with an apricot-coloured centre. It is a grand autumnal Rose.

MME. HOSTE is a pale yellow of great purity. The blooms are well built up and of great substance and size. The title

"yellow Roses" gives us rather a wide scope among these flowers, but I have endeavoured to keep within bounds, even by omitting such grand varieties as *Comtesse de Nadailac*, *Anna Ollivier*, *Jean Ducher*, *Princess of Wales*, *Francisca Krüger*, *Gloire de Dijon*, *Kaserin Freidrich*, *Bouquet d'Or*, *Mme. Berard*, &c., all of which might justly be styled yellows of different shade. D.

5526.—*Roses in pots*.—Except that I am afraid the pots are rather too large for the first potting, I think you have gone about your work in a business-like manner. The cold frame is a capital place for the plants until the end of May, when they will probably want more room. In any case plunge the pots to their rims in a bed of coal-ashes. With regard to pruning, if you keep the plants as cool as you can by removing the lights off them, except in wet or frosty weather, you may delay the pruning until the middle of March with advantage. I think if you cut all the strongest back to 9 inches above the pots and the weak ones to 6 inches you will do right. I do not think the plants will want re-potting until after they have produced two lots of flowers, or not until the month of August next year; even then they will not want larger pots, unless they are much stronger than I imagine them to be at that time. Strike off half of the old soil and re-pot in fresh. They will then be ready for forcing early the next year. The greenhouse will be too hot for

OUR READERS' ILLUSTRATIONS: Flowers of Rose "Harrison's Yellow." Engraved for GARDENING ILLUSTRATED from a photograph sent by Mr. J. McWalters, Armagh, Ireland.

break of the flowering eyes is secured. In pruning it is only necessary to thin out the weak shoots and remove the tips of strong and well-ripened growths. Weak growth is of little value upon the Austrian Briers. In the same class we have two single Yellow Roses.

THE AUSTRIAN YELLOW and the Austrian Copper. Both are good, the latter being one of the most superb single Roses grown. It is of vigorous growth, and possesses deep tints of bright copper, terra-cotta, and metallic-red. Once seen in their full beauty and freshness, these blooms are seldom forgotten. We also have the

YELLOW SCOTCH ROSES, which, although pale and very small, are almost perfect in shape and particularly free and hardy. Among other small yellow Roses we must not omit the

YELLOW BANKSIAN. I am acquainted with more than one garden where *Banksian* Roses grow well, but do not flower satisfactorily because they are injudiciously pruned. The *Banksians* flower early, and all the necessary pruning should be done at midsummer or soon after. Long shoots that have flowered should be entirely cut out, thus letting the air and light into the remaining growth and assisting its maturation during the autumn months. These Roses grow very late, and are much more tender than many; hence the need of giving the growth as early as possible, and a dry border to encourage early ripening. In the spring the

starts well into growth until too late in the season for its vigorous shoots to get matured. It was a seedling from Lamarque, and Nabonand has succeeded in getting a seedling from *Chromatella* which much resembles the parent, and is supposed to be hardier; he has named it *Comtesse de Beaumetz*, but it still remains to be proved, and I doubt if it will ever become so popular as *Maréchal Niel*. The above, with *Solfaterre*, *Ophiric*, and *Céline Forestier*, are the best of our old yellow Roses. During recent years many grand additions have been made to this colour, one of the most popular being

WILLIAM ALLEN RICHARDSON, which was sent out by Ducher in 1878. For some time it was not much grown, having probably shown its uncertain growth. It is a peculiar feature in this grand Rose that one plant may do well, and another in the same position and apparently under similar conditions will be far from satisfactory, growing scarcely at all. This same peculiarity is often found in *Maréchal Niel*, but not quite so frequently. It requires the same treatment as *Maréchal Niel*—viz., little or no pruning of the wood made the previous season. Its colour is difficult to describe and varies very much. Golden yellow, orange-yellow, yolk-of-egg yellow are all found; sometimes a bloom will be produced with only one of these colours, at other times two, or all three may be found in one and the same confusion, while it is not uncommon to find a flower pure-white. As a general rule they are golden-orange with a lighter edge.

the plants in the summer. They will be better in the open air after the middle of June. Your selection of Roses is a choice one for such a limited number. After the plants are well established in their present pots they may have those of a larger size in three years' time.—J. C. C.

5522.—**Growing Roses.**—By all means pot at once. You can then move them safely and use for either of the purposes you name. It is as well to pot now, even if you turn them out into the open border after settled in your new house. The size of pot depends entirely upon the size of root and plant. A comfortable size for the roots should be selected. If much growth is upon the plants they will need to be cut back; but I think from your description you could treat them exactly as you would a couple of young plants from a nursery. I should choose better varieties for the conservatory—say, *Maréchal Niel*, *L'Idéal*, or *William Allen Richardson* in place of the *Gloire de Dijon*, and one or other of the shorter-growing Teas instead of *Baroness Rothschild*.—P. U.

5192.—**Scotch Brilers.**—You can get these from any good Rose grower. The real Scotch Roses are of various colours and unnamed. There is a perpetual blooming variety called *Stanwell Perpetual* which should not be missed. Plant at once. Twelve dwarf Roses to stand in pots along a path out-of-doors would be *General Jacqueminot*, *Baroness Rothschild*, *La Franco*, *Madame Lambert*, *Bisher Holmes*, *Mrs. John Laing*, *Annie Wood*, *Monsieur Nonan*, *The Bride*, *Souvenir de S. A. Prince*, *Jean Ducher*, and *Perles des Jardins*. These will give variety of colour and are free bloomers. If great care is not paid to watering, and the outside of the pots partially shaded from fierce sunshins, you are not likely to succeed very much.—P. U.

5523.—**Climbing Roses.**—When forcing Roses it is of the utmost importance to avoid any draught, and this is always caused more or less by any ventilation. Sooner than do this, I would allow a considerable rise in the temperature and keep the atmosphere a little moister. Syringe according to the temperature and weather. I cannot say just how often, because so much depends upon other circumstances. A moist, spring-like atmosphere is wanted; but if the weather is extra dull and wet, cease syringing for a short time. Until the growth is some 4 inches long I would not advance over 35 degs. to 60 degs., but from that stage an additional 5 degs. to 10 degs. will not hurt.—P. U.

5193.—**Tea Roses, &c. for sale.**—*Marie van Houthe* is the only one of those you name which is likely to be satisfactory for your purpose. *General Jacqueminot* and *Catherine Mermet* will give many more flowers than *Marie Raby* and *Ethel Brownlow*, and are near enough of the same colour. You are not likely to find the sale of blooms from three plants worth the trouble.—P. U.

OUTDOOR PLANTS.

A GOOD HARDY ANNUAL.

BLUMENBACHIA CORONATA.

This has much to recommend it, the flowers being showy, the foliage elegant, and the growth

Blumenbachia coronata.

dwarf and compact. Like all the *Loasa* family the structure of the flowers is somewhat singular. The boat-shaped petals and the peculiar small scales between them, together with the bush-like bundles of stamens, render the blossoms very distinct, but the entire is so simple enough; it merely requires to be treated

as a hardy annual, but, like others from Chili, it is better to sow it in spring than in autumn. It continues to flower from July to September, if grown in warm, light soils. The other species in cultivation are *B. insignis* and *B. multifida*. The blossoms of *B. insignis* are pure white, 1 inch across, with a large serrated tooth on each side. *B. multifida* is of much stronger growth, more hispid with stings, and with much larger five-parted leaves, longer two-bracted flower-stalks, and broader obtuse petals. Both species are natives of the southern parts of South America. G.

5183.—**Best Dahlias.**—I have given the best twenty-four show varieties, and the best twelve Cactus kinds, as you scarcely want two dozen Cactus kinds. Of the show class select *Bendigo* (purple-crimson), *Colonist* (a distinct colour, quite free, fawn and chocolate shade), *Cauary* (yellow), *Ethel Britton* (blush, the petals edged with purple), *George Rawlings* (deep-maroon), *Glowworm* (orange-scarlet), *J. T. West* (yellow, the petals tipped with purple), *Harry Keith* (rose-purple), *John Wyatt* (crimson, shot with a scarlet shade), *Mrs. Glasscock* (white), *Mrs. Glastons* (a lovely colour, silver-pink, so very fine in form), *Queen of the Belgians* (cream-shaded with pink), *Rev. J. Goodblay* (maroon-purple), *Thos. Goodwin* (very intense in colour), and *Wm. Rawlings* (crimson-purple). The best of the fancy varieties are *Comedian* (orange, with crimson freckles, the tips of the petals white), *Gaiety* (yellow, striped with red and tipped with white), *Gen. Gordon* (yellow, with stripes of scarlet), *Chas. Wyatt* (deep-rose, set off by crimson flakes), *Flora Wyatt* (orange with stripes, and flakes of red), *Henry Glasscock* (buff, striped-rose), *Mrs. Saunders* (yellow, the petals tipped with white), *Peacock* (purple, tipped white), *Rebecca* (lilac, striped crimson), and *T. H. Girdlestone* (lilac, with flakes of maroon). Any or all of the following Cactus kinds are worth growing, and the flowers are of the true Cactus shape. Taking the well-known Juarez as the type: *Lady Penzance* (yellow, a clear, lovely shade), *Countess of Gosport* (pleasing in colour, the flowers small, but very neat and pretty in form), *Countess of Radnor* (a lovely shade, or shades, salmon-rose, molting in yellow, and the form distinct), *Robert Cannell* (magenta, shot with a satiny bluish shade), *Delicata* (pink, passing to yellow in the centre), *Kynerith* (quite of a vermilion shade), *H. Cannell* (deep velvety-maroon), *Honoria* (delicate-amber colour), *Juarez*, *Lady M. Marsham* (salmon), *Mrs. Hawkins* (sulphur-colour), and *Panthea* (bright salmon-red).—C. T.

6310.—Plants for the banks of pond.

—There is no lack of beautiful things for this purpose, enough to adorn every yard of the banks with a series of fine flowers. They may be divided into two classes: those that love moisture at the root, but prefer not to be actually in the water, and others that may be even in the water itself. Of the first class I should begin with the *Globe-flowers* (*Trollius*), and make a feature of them, they are so fine, showy, and early. Then comes the *Iris*, a perfect lust; *I. germanica* in its varied form, but above all such lovely species as *I. sibirica*, *Mouneri*, *arosa*, and *schrolobouca*, and last, but far from least, the *Kompfer* or *Japan Iris*, which need moisture more than any, and do not mind if they are actually in water to the depth of 3 inches or a little more. *Spiraea*, such as *palustris* and *venusta*, are essentially water-side plants, and so is the purple *Loosestrife* (*Lythrum Salicaria*). *Day Lilies* are admirable on pond-banks, and so is the tall *Lupin*. In the water itself there should be many things, including those that are natives, such as the *Boy Bean* (*Menyanthes trifoliata*), the great *Water Buttercup* (*Ranunculus lingua*), with flowers as large as florins, and the flowering *Rush* (*Batium peltatum*). Other good things not natives are the *Red Water Hawthorn* (*Aponogeton distachyoides*), *Galla palustris*, *Sagittaria Japonica* fl. pl., one

of the showiest of water plants, with full spikes of double flowers, *Orontium aquaticum*, commonly called the *Golden Club*, as it thrusts its yellow club-like spikes of bloom above the water, and *Pentederia cordata*. This last in shallow water is exceedingly handsome, throwing up leaves on long stalks 2 feet high, and above them long spikes of rich-blue flowers. I might extend the list of things available, but if "C. C." takes all these in hand he will make his ponds a perfect water-garden of lovely flowers for at least six months of the year. To make the thing complete the ponds should contain some of the many new and noble hardy *Water Lilies*, whose advent marks a new era in water gardening.—A. H.

TWO FINE IRISES.

IRIS IBERICA (Fig. 1).—This is one of the most singular of the *Iris*, and very handsome. The flowers are of good size; the upright petals are white, pencilled and spotted with purple or violet, while the drooping petals or falls are veined with dark-purple or purple-black on a

Fig. 1.—*Iris Iberica.*

yellowish ground, with a conspicuous dark blotch in the centre. This is the colour of the commonest form, but there are several, and one, ochreous, is very distinct. *Iris iberica* is far easier to cultivate than most persons imagine, being perfectly hardy, and not at all fastidious as to its requirements. It thrives best in a rich fibrous loam, where it can send its long roots deep into the soil. The rhizome does not require to be planted deep, but only just below the surface. In most cases the roots perish when planted deeply. The rhizome during winter is very impatient of moisture, and should be kept comparatively dry. Coarse river sand should be used, the rhizome being planted completely in it in the same way as many bulbs are planted. By this means it is kept rather dry during the winter, and great assistance is given to the plant in summer, as the young shoots can easily force their way through. Under this treatment the plant grows more freely, and can be easily multiplied by division of the rhizome. It is admirably suited for the rock-garden, or for the socket border, and, when better known, it will find a place in every garden. It flowers in spring, and though the blossoms are of somewhat short duration, their extreme beauty amply compensates for this drawback.

IRIS SUSIANA (*Monaring Iris*)—Fig. 2, p. 715—One of the most singular of all the flowers of temperate and northern climes. It grows 1½ feet to 2½ feet high. The flowers produced in early summer are very large, and are densely spotted and striped with dark-purple on a grey ground. It should be grown in sunny nooks in the rock-garden, or on sheltered banks or borders, but always in light, warm, and thoroughly-drained soil. I have seen it thriving as a border plant and flowering well in a garden near Broadstairs. It may be treated as perfectly hardy in some parts of the county; but a dry bottom and a free soil are essential. In cold districts or on heavy soil the protection of a hand-light would be useful in winter. It is a native of Asia Minor and Persia. It is increased by division. F.

 5184.—**Planting Dahlias.**—Plant out in April, and cover at night, with the dried flower-pots till the weather gets warm end of May. E. H.

DEEP CULTIVATION.

If trenching or double digging was necessary in hygene lays, when cropping was not nearly so rapid as it is now, it follows as a matter of course that it is more needful now, when we are not content with crops following each other almost before the land is cleared; but many go in for double cropping, and we find all sorts of Winter Greens, Broccoli, Savoys, &c., getting established between the rows of Potatoes, so that the land is never at rest. In advocating trenching the difficulty with many is to get any ground vacant during the winter season, when it can be done; but there is not the slightest doubt that deep cultivation is the only way to effectually guard against drought, and with the experience of the summer of 1893 still fresh in our minds it would be folly not to guard as far as possible against similar failure in the future. Artificial watering, mulching, &c., are only aids to ward off the effects of drought. The real cure is a deep, thoroughly pulverised, and liberally enriched root-run, where the crops can defy the effects of drought. In gardens of limited area, such as amateurs generally cultivate, the best plan is to set it out in plots, and crop it so that a portion should become vacant in the winter season and receive its turn of trenching, whereby it will really be made like new soil; for with all our skill in chemistry we do not improve on Nature so rapidly as to be able to put into the soil the exact elements that each crop requires, for the object of our forefathers allowing land to lie fallow one year and cropping it the next was that Nature might restore to

EXHAUSTED LAND, through the agency of frost and rain, the very things it was deficient of. There is little chance of going back to this very primitive mode of letting land, at least in gardens, restore itself simply by lying idle. We, however, must take care that we do not verify the old motto of the more haste the less speed becoming applicable to garden lands, for it is no use hurrying a large space of any given crop into the soil if by better culture we could have grown an equal amount of produce on a smaller area, and I am fully convinced that deep cultivation enables this to be done, and as regards manure, there is little doubt but that double digging saves manure, for it brings to the surface and within reach of the roots those nutritious elements that have been washed deeply down by heavy rains until they were practically useless; but by bringing them up to the influence of the sun and air they again become available for plant food. In trenching I utilise all the roughest of the garden refuse by burying in the bottom of the trenches all the old stems of Broccoli, Cabbages, or any of the Brassica tribe. For old Strawberry beds that have become weedy there is no cure like burying the whole mass two spits deep, if possible, in the autumn or early part of the winter, as is the best for the work, for then the newly turned-up soil gets the whole of the winter to become mellowed before spring-time comes round again; but still any time during winter does very well, for trenching is good work for cold weather, and when the depth of good soil is not sufficient to allow of the bottom spit being turned right on the top of the first, it should be well broken up with forks, so as to increase the depth of friable soil, the best antidote for crops suffering from drought yet invented.

JAMES GHOOSH, *Gosport.*

5517.—Treatment of a lawn.—You had better set about raking up the Moss at once with an iron toothed rake, and afterwards give the lawn a good dressing of rich soil which has been passed through a coarse-meshed sieve. Wood-ashes or the charred rubbish of the garden is one of the best fertilisers for lawns if laid on next month. There is another plan open to you, and which I have found in practice to be useful—that is, instead of using the lawn-mower in the spring, to cut the Grass with a scythe, and pare it down as close as you can get to the soil. If you continue this treatment through the summer the sun will scorch up the Moss.—J. C. C.

5503.—Beds of Begonias.—Unless you have a nice warm-house, pit, or a hot-bed, and some amount of experience in the matter, it will be wiser to purchase the plants in the open young plants in May or June, than to attempt

to raise the seedlings yourself. Plants from seed sown in January, or at once, in a heat of 65 degs. or 70 degs., and kept growing on rapidly and vigorously, will begin in bloom in July, or sometimes in June, of the same year, but the greatest care and a certain amount of skill are absolutely necessary, and even then the flowers are later than from year-old tubers. On the whole, you had better procure tubers in March—good seedlings selected as to colour are decidedly superior, as well as less costly, for this purpose than named kinds—start them in boxes of rough sandy soil, in a gentle heat, or the warmest corner of the greenhouse, pot them singly when in growth, harden off in cold frames in May, and plant out about the second week in June, in light, free soil made rich with decayed manure, leaf-soil, or spent hops.—B. C. R.

5519.—Pelargoniums out-of-doors in Sussex.—Pelargoniums are not very good plants for a wet district, and for this purpose I should rather prefer Tuberosa Begonias which delight more in moisture. Still, for the

every autumn from cuttings, and kept through the winter in a cold frame. This was a success. A dwarf Yellow Nasturtium did fairly well. Harrison's Musk was a success in a damp situation, mulched with manure, but failed in a drier spot; but the showiest thing of all was a dwarf double yellow French Marigold, raised from seeds in the spring. Calliopais grandiflora, pegged down, Yellow Tuberosa Begonias will be a success, only they are rather expensive to start with. The same may be said of Yellow Carnations, but the Carnations do not give enough colour to suit everybody.—H. H.

5516.—A mossy lawn.—More than one correspondent inquires about mossy lawns, but there is really only one remedy when the Moss has taken complete possession, and that is to returf or resow. The presence of Moss indicates bad drainage, and a badly-drained lawn is never successful. It cannot be, as the soil is always in an unwholesome, waterlogged condition. The quickest way is to returf those parts badly matted with good fresh turves, as resowing

Mourning Iris (Iris susiana). (See article "Two Fine Irises" on page 714.)

open you cannot do better than select of the Zonals such fine kinds as Henry Jacoby, which has vivid crimson flowers produced in a bold truss, King of the Boddlers (scarlet), Vesavia, well-known as one of the best of all this class, John Gibbons (orange-scarlet), Triomphe de Stella (orange-scarlet), and West Brighton Gem (scarlet), a very fine bedder. Beckwith's Pink is a good pink kind, also Mrs. Turner, and amongst salmon-coloured varieties worthy of note is Lady Mason, which has reddish-salmon flowers, and produced very finely. Of the Ivy-leaved varieties, the old Mme. Croisse is still one of the best, and other worthy kinds are Rye-croft Surprise, which has neat trusses of salmon-pink flowers, H. Camell (rose), Souvenir de Chas. Turner (deep-pink, the upper petals feathered with maroon), Mme. Thibaut (deep-pink), Juanno d'Arc (white, touched with lavender), Congo (pale-lilac), Comtesse Harace de Choiseul (rose), and A. F. Barron (lilac-rose).—C. T.

5496.—Bedding plants.—I have tried many substitutes for Calceolarias, including a few self Antirrhinum, which was propagated

means a rather weakly sward for ploughing upon during the coming summer. The dressing of soil advised was correct, and a very good thing to use. Rake out the Moss, resow or returf; the latter is the better plan in the majority of cases.—C. T.

5524.—English guano for a garden.—The Native guano is no doubt what is meant in this inquiry, and this is frequently advertised in GARDENING. I have found it to be a very good substitute for stable-manure for all garden crops; also for fruit-trees, if used in moderation. At the same time, I do not think any kind of fertiliser will take the place of stable or farmyard manure—that, however, is not always obtainable. It is in such cases that the Native guano or Clay's Fertiliser and other concentrated manures are valuable, and they invariably do the most good when they are mixed up with the soil before sowing or planting.—J. C. C.

5472.—Sulphuric acid and weeds.—It is not of much use to apply sulphuric acid, but now I wait till the Grass shall be blowing about, and then whatever is applied will be more effectual. One part of sulphuric acid to 20 of water will do the trick, and will not kill strong-rooted culs.—H. H.

THE KITCHEN GARDEN.

WITLOOF, OR CABBAGE-HEADED CHICORY.

This Witloof (Fig. 1) is the forced and blanched sprout of a particular variety of large-rooted Chicory named Brussels Chicory, from the name of the city where its culture originated. Witloof may be brought to table either raw, as a salad, or cooked and seasoned in various ways. In the first form it very much resembles Common Chicory or blanched (Barbe-de-capucin) (Fig. 2), and when served up in the last-mentioned way it reminds one especially of boiled curled Endive. In any form it is an agreeable and wholesome vegetable, with a slightly bitter taste and remarkably delicate in

Fig. 1.—Witloof, or large Brussels Chicory (one-third natural size).

flavour. Witloof can only be produced by using the particular variety of large-rooted Chicory which I have just mentioned, and which is distinguished by the broadness of the leaves, and especially by the great size of the midrib. These leaves, when they are blanched by forcing the plants underground, form a sort of Cabbage-like head, very solid and compact, and of an ivory-white colour, bearing carriage well, and, when properly attended to, keeping fresh for several days. This explains how it is that Paris and London are almost exclusively supplied with Witloof grown in Belgium, where it is raised at less expense, although there is nothing of either mystery or difficulty in the process. Our market-gardeners are certainly able to do it quite as well as their Belgian brethren, and even the owners of private gardens can without any difficulty and at a trifling expense raise Witloof if they will only conscientiously carry out the instructions which we here endeavour to give as clearly and as briefly as possible. In the first place it is indispensably necessary to obtain seed of the large-rooted Brussels Chicory genuine and

TRUE TO NAME, as this is the only kind which produces the large leaves and midribs which are essential to form the Cabbage-like heads. With any other kind of Chicory the most painstaking efforts in the process would be absolutely thrown away. The seed should be sown, during the month of June or at the beginning of July, in soil that has been deeply dug and well prepared and, preferably, in drills drawn from 6 inches to 12 inches apart, the seedlings being subsequently thinned out so as to leave from twenty to thirty plants to the square yard. If the seed is sown too early there almost always results a large proportion of plants which run to seed the same year. Seed may also be sown for transplanting, and this method is to be especially recommended in market-garden culture, where it is important to have ground occupied by any particular crop for as short a period as possible. In this case the seed is to be sown in a nursery bed in June, and about July 10 the seedlings may be planted out in a bed from which some early crop has just been taken, and at a distance from one another of about 6 inches in every direction. In October the plants will have attained their full growth, and the roots will then be as thick as an ordinary spade-handle. They are now to

be lifted from the bed, the leaves cut off at about 2 inches from the neck, and the roots shortened to the length of about 6 inches. At the same time all lateral growths are cut away, and also any shoots which may have pushed around the principal one, which alone is to be retained. The roots thus prepared are then at once placed in an upright position side by side in the bottom of the trenches which have been prepared for the forcing. These trenches should have been opened in a well-drained part of the garden or where the water does not lodge in the soil naturally, and should be about 16 inches in depth below the level of the garden. The bottom of the trenches should have been well broken up so that the roots may be readily inserted in the soil. When the full complement of roots has been deposited in a trench, some of the soil which was taken out in making it is then shovelled back so as to fill up the interstices between the roots and cover the latter up to the necks, which should all have been placed at the same level. After this a layer of about 8 inches deep of comparatively dry soil is shovelled in. Soil proper for the occasion may be easily prepared by placing a sufficient quantity in heaps under a shed or other shelter some weeks beforehand.

The trenches are usually from about 4 feet to 4½ feet wide, and may, of course, be as long as is convenient. After a trench has been furnished with roots and dry soil, as just described, portions of it are forced in succession, according as supplies are required. The forcing is effected by covering the requisite portion of roots in the trench with a layer 8 inches to 12 inches deep of fermenting manure, and in from twelve to fifteen days' time the soil will have become sufficiently heated for the production of Witloof. The manure may then be transferred to the next portion of the trench that is to be forced, fresh manure being added to it to keep up the heat as may be required. The Cabbage-like heads of Witloof are not fully developed until after twenty days have elapsed, but when the manure is removed a covering of litter or straw mats suffices to retain the heat and to finish off the growth of the blanched heads. These when taken up are cut off from the roots with a small portion of the neck attached to them; they are then sorted in sizes and packed in the square baskets in which they are sold in the markets. The production of Witloof, easily accomplished in any country, is particularly to be recommended for adoption in the kitchen gardens of country houses in localities far remote from markets.

CHICORY (Barbe-de-capucin).—Forced in winter in a dark place, the common Chicory plant yields a much-esteemed winter salad material. In producing it, use is made of plants that were sown rather thinly in the open ground from April to June. At the beginning of winter these plants are taken up and the leaves are cut off to within about half an inch from the neck of the root. Then, in some dark place, where the temperature is not too cold, sloping beds are built up, composed of alternate layers of sand or dry soil and Chicory roots, care being taken to place the heads of these at the outside of the bed, so that the leaves may have room to grow freely. If the soil of a bed appears to be too dry, it is slightly watered and the bed is then left to itself for about three weeks, when, if the temperature has not fallen too much, leaves from 8 inches to 10 inches long may be gathered. Of late years some growers in the neighbourhood of Paris have begun to use for this purpose the large-rooted kind of Chicory, which they force as soon as it has attained the thickness of a man's finger. The roots of this kind of Chicory, being very straight and regular in shape, are very easily placed in position in the beds, and the leaves which they yield are generally broader and more vigorous in growth than those of the common Chicory plant. V. A.

5404.—**Grubs and vegetables.**—Dress the land freely with soot, salt, and lime. Trench it up 2 feet deep, then apply the dressing with any manure you may have and dig it in. If the land was properly worked there would be fewer insect troubles.—E. H.

5334.—**Tomatoes under glass.**—I should advise "E. H." to give "Ladybird" Tomato a trial. It can be obtained from Messrs. Veitch, King's-road, Chelsea. I grew it here last year and it is one of the finest-setting Tomatoes I know of, bearing bunches of medium-sized, red fruit at almost every joint, making the house quite a show. It is also a good variety for outdoor work.

5507.—**Unsatisfactory Celery.**—The rusty-looking marks complained of are the result of slug attacks immediately after earthing. The best preventive is quick-lime, soot, and wood-ashes, in equal parts, sprinkled on the soil amongst the plants and at the sides of the trench, so that in moving the soil the mixture will render the soil distasteful to the small black slugs that are the cause of the nuisance.—S. P.

5508.—**Soil for Tomatoes.**—It is not necessary to change the soil every year for Tomatoes under glass; but it should be worked and deepened every season by digging a little deeper, and mixing a little more of the subsoil with the surface-soil. I have grown four crops in the same house in succession with deep stirring and manuring every winter, and top-dressing during the growing season, and the last crop was as good as the first. I know the Worthing growers consider the soil should be changed after two or three years, but their soil is heavy, and ours rests on a chalk base 50 feet deep.—E. H.

5505.—**A Mushroom failure.**—No one, I expect, will contend that Moss-litter-manure is so good for Mushroom culture as the manure made from straw-litter. It is, in the first place, wanting in elasticity, and when beaten down it sometimes fails to heat sufficiently to work the spawn properly. I should not use Moss-litter-manure for Mushrooms, except where the supply of common straw-manure failed, but where Moss-litter is used less treading or beating should be given. I have seen good crops of Mushrooms grown with it, and it comes in useful if a sufficient supply of other manure cannot be had. It is very good manure for vegetables of all kinds when dug into the garden.—E. H.

5474.—**Beet Peas for market.**—I happen to live in the midst of a Pea-producing district for markets, and have had considerable opportunity to observe the system of culture and the varieties grown. The Pea likes rich, rather deep soil if it can be obtained; but I have seen splendid crops of early Peas taken from light soils of a shallow nature. Late Peas are apt to mildew badly on light soils, and they are also more liable to be attacked by thrips,

Fig. 2.—Chicory, blanched (one-sixth natural size). (See article "Witloof.")

and this troublesome insect quite spoils the appearance of the peas for market. The variety most frequently cultivated now for early crops is William the First, a very fine Pea, with dark-green pods. American Wonder has been tried, and has given satisfaction on some farms; others do not care about it. For late crops on good soils of a medium clay, No Plus Ultra is profitable. The dwarf Peas are sown 2 feet apart, the medium 3 feet, and the late tall Peas 4 feet. No sticks are used in any case, and the tops are switched off with a reaping-hook.—J. D. E.

5483.—**Spring-sown Onions.**—Soot and salt will be very beneficial on light sandy soil intended for Onions where the midget is trouble-

some. Give a dressing of salt and soot at once; the salt may be applied at the rate of twenty pounds to the square rod, and at least a bushel of soot, both to be lightly forked in. About the end of May or a little earlier, give a light dressing of soot to keep the Onion-fly from the beds of Onions. They dislike the flavour of soot, and if this is applied about the time the flies lay their eggs the insects will seek elsewhere for suitable plants for their young brood.—E. H.

5491.—Planting Potatoes.—Something depends upon the size of the seed; but if of moderate size you will require for your plot of ground (which is just about half an acre in extent), about 15 bushels of seed. This is reckoning the seed is planted 10 inches or 12 inches apart, in rows 2½ feet to 3 feet asunder. Some of the most useful and productive Potatoes for ordinary purposes are Sharpe's Victor, and Veitch's or Myatt's Ashleaf (early), Beauty of Hebron and Duke of Albany (succession), and Reading Giant, the Prince, and Magnum Bonum (late). On such soil as yours, a moderate dressing of stable-manure (say 10 tons per acre), is almost indispensable, and you may also use a little superphosphate (2 cwt. per acre) and salt, or nitrate of soda, with the best results. Of the latter, apply it as a top-dressing before earthing up.—B. C. R.

5492.—Culture of Vegetable Marrows.—One of the causes of Vegetable Marrows getting out of condition is planting in very rich compost. They are always more prolific when only a moderate quantity of manure is used—say, half a barrowful to each hill, to be mixed and blended with the soil. Soot, rank growth produces fruit which rots at the ends and falls off.—E. H.

HOUSE & WINDOW GARDENING.

A FEW GOOD SCENTED FLOWERS.

PLANTS with highly perfumed flowers or foliage are always in great request in rooms and for bouquets, &c., and, as a rule, they are eagerly sought after by those who value real worth. The following are all easily grown and suitable for small gardens:—

ALOYSIA CITRIODORA (Lemon Verbena) is a deciduous plant with beautifully scented foliage. It is sometimes grown as a wall-plant out of doors, but needs covering up securely or a severe winter will kill it to the ground. As a pot plant it strikes readily from cuttings and grows freely in any good potting soil. Pinching in the strong shoots that are outgrowing the rest is all the attention it needs to insure well-furnished bushy plants. In winter it only needs keeping safe from frost, and if treated like Fuchsias does well.

DAPHNE INDICA is a beautifully perfumed flower (the commoner hardy kinds are known as Wood Laurels). It is increased principally by grafting on the Wild Wood Laurel, and is of rather slow growth, but a plant or two in the greenhouse will scent the whole structure for weeks at this early period of the year.

FREESIAS are among the most beautiful of bulbous plants, the flowers having a delicate yet powerful perfume. Their culture is now getting to be more generally understood, and they require nothing that amateurs cannot give them. Pot the bulbs, say about a dozen in a 6-inch pot in July, and set them in a cold frame, keeping rather dry until they start to grow and root, then water freely. Keep close to the glass in all stages of growth or the foliage will get long and weak. A temperature of about 50 degrees suits them well, and by having some kept in cooler quarters a long succession of bloom may be maintained. Strong spikes branch out into several side branches of flowers.

HELIOTOPES are old favourites both for the flower garden and as pot plants; they are readily increased by cuttings of the soft young shoots, and good plants may be grown in one season. The dark-flowered ones are generally the most favoured; but as regards scent there is little to choose, as they are all fragrant.

GERANIUMS, SCENTED-LEAVED, are numerous, and of easy culture. The old Oak-leaf is a familiar cottage window plant, as it flourishes well in the dry air of ordinary living rooms. Cuttings strike freely if kept rather dry, and rapidly make good plants.

MUSK is too well-known to need any description. The roots lie dormant in the soil during the winter, but start very early into growth.

The plants should be shaken out of their pots and divided in early spring, and plenty of moisture is needed for Musks. The old-fashioned small yellow-flowered sort has the strongest perfume; but Harrison's Giant Musk is now much grown as a window plant, as well as for bedding-out in summer.

MIGNONETTE is still, probably, the most popular of all scented flowers, both as a pot plant and for the flower garden, as even those dwellers in town who have not a foot of garden ground will still grow their Mignonette in window-boxes or pots, and from peer to peasant no garden is complete without it. The old small-flowered variety still holds its own for perfume against all the Giant varieties too numerous to mention.

VIOLETS are the favourite winter flower, and many acres of land are devoted to their culture in market gardens. The hardy single blues are very popular, but the tender Neapolitan are well worthy of culture by any who can devote frames for their protection during the winter months.
J. GANNON, Gosport.

INDOOR PLANTS.

THE DATE PALMS.

ANYONE who notices how vigorously the common Date Palm grows in a large cool-house must welcome the smaller species of the same genus,

The Slender Date Palm (*Phoenix tenuis*).

which, while thriving in a similar temperature, are more convenient as regards size, and are of easy culture. Palms are getting so common in our gardens now that the selection of some cool-house specimens is not difficult. One or two of these placed in a corner of a greenhouse make a great improvement, not only in effect, but in simplifying the grower's labour and care—looking, as they do, well at all seasons, and heightening so much the beauty of a few fresh flowers. Two good kinds for small pots are *Phoenix tenuis* (here figured) and *Phoenix reclinata*.

5297.—Libonia floribunda.—This should have a warm greenhouse, especially when flowering; but it is not very difficult to grow, although seen less nowadays than formerly, when so much attention was not given to Orchids. You do not state that you need particulars as to culture, but I suppose so from the query. The plants may be propagated from cuttings in the spring, and should be inserted in pots of sandy soil and placed in a gentle heat. When rooted pot the cuttings off separately, and at all times when well-established give them plenty of air, otherwise the growth will get long and weakly. Equal parts loam and leaf-soil forms an excellent compost, drain the pots well, and for flowering the plants in, they need not be more than 3-inch or 6-inch size. It is important to remember to keep the growth well hardened. The great enemy of the

plant is red-spider, which is kept away by syringing freely in the summer. *L. penrosiensis* is distinct from *L. floribunda*. The former is a hybrid; it is a good acquisition, the flowers being of much richer colour than those of the type. They are borne in the winter months.—F. P.

5432.—Oil-stoves.—I have many times stated that these are very useful for small houses if kept clean and well trimmed, and used only when really necessary. I know that a pan of water is often placed on such stoves, but I do not agree with or practise this, except in certain cases, because, as you say, the steam or moisture therefrom does the plants harm rather than good. The little "Beatrice" stoves, with a 6-inch wick, are as good as and cheaper than any other form, and one or two of them, with a "radiator" on top, will exclude a good many degrees of frost from any moderate sized and fairly sheltered greenhouse or conservatory.—B. C. R.

5430.—Heating a greenhouse.—You want a larger boiler and another 4-inch pipe connected with the others, so as to have two flows and one return over the same length as the existing pipes; even then you must not expect only to keep out frost. It would be hardly safe to have a larger boiler without increasing the length of the piping. There would be danger of the water boiling over if you were not at hand to check the fire, which would probably end in the boiler bursting when all the water has been forced out of the pipes.—J. C. C.

—Unless the house is lofty the amount of piping mentioned ought to be capable of at least excluding frost if well heated, though another row would be a decided advantage. These very small boilers are of little or no real use—mere toys, in fact—as they will not keep aught more than five or six hours at the outside. A well-built flue would be much better and more dependable, or for a few shillings you could purchase a coil, which if properly set in brickwork (by no means a difficult matter, by the way) would afford ample heat with a very moderate consumption of fuel. A 1-inch coil with four turns or "laps" would be about the right size.—B. C. R.

5298.—A banging-basket.—You do not state the kind of plants you require for the house, as there are many things that may be used for the purpose. The usual way is to first line the basket with moss to prevent the soil getting out, then fill up with soil, moderately light, and well-drained. Amongst flowering plants you can select Fuchsias and Ivy-leaved Pelargoniums, especially the variety Mme. Crousse, to hang over the sides. I have had a plant of this in bloom in a greenhouse for nearly the whole year, and the double

rosy-coloured flowers are very pleasing. Of course, the Mother of Thousands (*Saxifraga sarmentosa*) may be employed, and for the summer annual *Convolvulus*, or the pretty blue-flowered *C. mauritanicus*. Of Ferns you cannot have anything better than the beautiful *Nephrolepis exaltata*, or such a trailing plant as *Ficus repens*. The *Lachenalias* are very fine for baskets, and succeed well under such cultivation. Reference to last year's volume of **GARDENING** will give you the required information about the last named plants.—F. P.

5440.—An unsatisfactory Heliotrope.—Are you certain the late frost did not penetrate to the plant? If the glass is close to it, I should be inclined to think the excessive cold was too much for the Heliotrope. Sudden changes in temperature, such as would be caused by a very cold night followed by the warmth generated by the kitchen during the day, would probably cause the mildew, also the falling leaves, &c. Smoke of any kind is injurious to this greenhouse plant.—F. U.

—The temperature during the frost was probably too low.—E. H.

5419.—Winter-flowering "Geraniums."—Certainly the plants should be cut down when past their best, which will be the case very shortly now. Harden them off a little by exposing them freely to sun and air, and reducing the supply of water at the root for a time; then cut them back as hard as you like. The top and side shoots should be inserted as

outtings, placing them singly in small pots ("thumbs"), or five or six round the side of 4-inch pots. They will soon strike roots in a moderate and rather dry warmth, and may either be utilised for bedding-out purposes, or if grown and potted into 6-inch pots in June will make capital plants to flower again next winter. The old cuttings may either be grown on into large "specimen" plants, or be thrown away.—B. C. R.

—It is customary to cut back winter-flowering "Geraniums" now for the purpose of striking cuttings for next winter's blooming. The old plants after being cut back will quickly break, and if repotted or top-dressed will soon be in blossom again, and if a shift is given they will bloom all summer, and may be used for window-boxes.—E. H.

5423.—**Climbers for a greenhouse.**—The wall would look very pretty covered with Ivy-leaved "Geraniums." They would cover it in one season, and the blooms would be nice for cutting. *Ilabrothamnus elegans*, *Plumbago capensis*, *Clematis indivisa lobata*, *Heliotrope*, and *Fuchsia* are all useful wall plants.—E. H.

—If the Rose does well and is properly trained, it will soon cover the entire space unaided. But, of course, the growth can be restricted, and if the wall gets plenty of sun, as it should do to suit the Rose, two of the best subjects would be a *Heliotrope* and either an Ivy-leaved *Pelargonium* or a *Plumbago capensis*.—B. C. R.

5477.—**Tree-Carnations from seed.**—Seedlings raised now under glass and planted out in June, potted up in September, will flower some time next winter or early in the following spring.—E. H.

5181.—**Seeds of Castor-oil plants.**—To grow this plant large enough to be of any use under the same season, the seeds should be sown in a warm house or pit at once and pushed on as fast as possible. Any good soil, such as is used for potting soil-wooded plants, with a little sand added, will do for raising the plants.—E. H.

5488.—**Arum Lilies.**—The variety "Little Gem," flowers very freely, and is a pretty little plant. The old yellow spotted variety, *Hastata*, is very distinct and pretty; the colour is deep yellow with a black blotch at the base of the flower. Its price is about 2s. 6d. to 3s. 6d. The newer species, *Calla Elliotiana*, has much larger deep yellow flowers, and as it is still scarce is necessarily very dear; but it is not difficult to grow and flower freely. Its price would be a guinea per plant. Large plants would be double this price or more.—J. D. E.

BEDDING PLANTS FROM SEED.

The last sudden and severe frost, accompanied by snow and almost a gale of wind, will doubtless have left its mark on the stock of tender bedding plants, and steps should be taken at once to make good the gaps, or at least to provide substitutes for those that cannot be replaced. The following are all useful plants that can be raised in quantity from seed, and if sown at once, even without much artificial heat, they may be grown into good plants by the month of May. Solar heat increases daily, and a pit or frame with a little bottom-heat and covering over the glass at night will answer well for bringing on seedlings.

AUERATUMS, in several varieties, of which Imperial Dwarf Blue and White are most useful for bedding, and of the easiest culture. Sow the seed in pots of light rich soil, and when the seedlings are large enough to handle prick off into boxes in which they may remain until planted in the open air beds.

ANTERS (China) of all the leading varieties make beautiful beds, although they are not generally classed with bedding plants; they require no artificial heat, but merely the protection of a glass roof, and may be sown in boxes or in the soil of a cold frame.

BENONIAS of the tuberous-rooted section have of late become very popular as bedding plants. Now in pots, using very fine soil, pressed down firmly, as the seed is very minute, and cover very lightly. A brisk heat is needed to push the seedlings on, or they will not be large enough for this season's bedding; but if enough of old dry roots are available it will be advisable to grow on in gentle warmth, and after carefully hardening off plant out in the reserve garden to make growth the first year.

CENTAUREA CANDIDISSIMA, one of the most beautiful of silvery foliaged bedding plants, being dwarf, compact and half-hardy. It makes a splendid edging to *Coleus Verschaffelti*, *Canone*, or *Beet*.

GAILLARDIAS are not nearly so much grown as they deserve to be, as they are of rich varied colours and most persistent bloomers. Sow in gentle heat they will be fine plants by

May. *G. Lorenziana*, double fringed, and *O. hybrida grandiflora* are the best varieties.

HELIOTROPE, although generally grown from cuttings, may be increased by seed. The dark-flowered varieties like *H. peruvianum* and *H. Voltarianum* are the best.

LOBELIA (Blue) is indispensable for edging, and if there is any lack of old plants to get outtings from, seed should be sown at once, and the seedlings pricked off in boxes directly they are fit, keeping the points pinched out to ensure dwarf bushy plants.

NICOTIANA AFFINIS (the sweet-scented Tobacco plant) is in great favour of late for bedding. It answers well for the background of mixed borders or for mixing with sub-tropical plants.

PERILLA NANKINENSIS, one of the darkest of foliage plants, very free growth, useful for contrasting with other foliage plants of easy culture.

PETENIAS, Double (see cut) and Single, are splendid plants for masses of colour, and succeed well in dry soils and situations. The single varieties are, however, generally the best for ordinary bedding.

PHLOX DRUMMONDI has of late years been very much improved; not only are the individual blooms of much greater size, but the colours are much more distinct. Sown in a cold house or frame and pricked out singly, pinching the tops to make bushy plants, they will soon cover the soil when planted out, and make beautiful beds.

PYRETHRUM AUREUM (Golden Feather), very largely used for edging and carpeting beds and borders; sow in pans or boxes, and prick off

Flower of a Double Petunia.

directly the seedlings are fit to handle. The pale lemon-colour of the foliage renders it very effective in carpet bedding.

SALVIA PATENS, one of the most beautiful of blue flowers; old plants form tuberous roots, but if these are not available they can be readily increased by seed.

STOCKS of several varieties, but notably the Ten-week, are excellent for filling flower-beds and borders, although they cannot be strictly termed bedding plants, but the greater the variety in the flower garden the better, and

STOCKS are not only beautiful flowers, but are highly perfumed, and last a long time in flower. To get good plants the seed should be sown in a cold frame, in drills about 6 inches apart, and after the seedlings are above ground they must be freely ventilated, and the soil kept moderately dry on the surface, to avoid damping of the young plants.

TROPEOLIUMS of the dwarf kinds are very effective for bedding. *Crystal Palace* (scarlet) and *Lobbianum* (brilliant) make gorgeous masses of colour. The seed should be sown in March, and planted out early in May.

VERBENAS are not so much grown as they were a few years ago, owing to a disease affecting them, so that they gradually die away, but seedlings appear to escape the scourge, and make very pretty mixed beds. Being of dwarf spreading habit they quickly cover the soil, and flower continuously.

VIOLAS are usually increased by cuttings, or division of the roots, but the drought last season having destroyed the stock in a good many gardens, recourse must be had to seed, which, if sown at once, will yield plants fit for planting in April.

RULES FOR CORRESPONDENTS.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.*

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by advising, as far as their knowledge and observations permit, the correspondents who seek assistance. Conditions, soils, and means vary so infinitely that several answers to the same question may often be very useful, and those who reply should do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in GARDENING should mention the number in which they appeared.

5542.—**Crops after Celery.**—What are good kitchen garden crops to follow after Celery?—O. A.

5543.—**Seakale-roots.**—Are Seakale-roots of any good after they have been forced?—TADWILLOSK.

5544.—**Dwarf Tomato.**—Which is the best dwarf-growing, short-jointed Tomato having smooth fruit?—M.

5545.—**Wireworms.**—Will "E. H." kindly supplement his interesting account of wireworms by giving a description of them as usually found?—ALPHA.

5546.—**Hyacinth bulbs.**—Would someone kindly tell me if I can preserve Hyacinth bulbs till another season without planting them out? I have a quantity left on hand.—J. HORN.

5547.—**Growing Heliotropes.**—Will someone kindly give instructions for growing Heliotropes? I have several plants, but have failed to get them to flower well.—W. D.

5548.—**Seakale-roots.**—After the roots have borne produce ought they to be dug up or left in the ground until next year? If to be dug up ought they to be put in sand?—LUX.

5549.—**Orchids for a greenhouse.**—Will someone kindly give me the names of a few good flowering Orchids which will grow in an ordinary greenhouse with other plants?—W. M.

5550.—**Heliotropes from seed.**—Will anyone be kind enough to tell me if I can raise Heliotropes from seed in an ordinary garden frame, and what is the best time to sow?—BUNSLER.

5551.—**Pure rain water.**—Will someone kindly tell me how to keep rain-water pure, as I find after standing in the sun some time it turns green and gets full of insects?—KUSTIC READER.

5552.—**Scaring birds.**—Will someone please to inform me where I can obtain a scarce sparrow-hawk, as the birds peck all the buds of my Gooseberry-bushes?—CONSTANT READER.

5553.—**Chrysanthemums for show.**—Would someone kindly give me a selection of what varieties to grow, together with a few cultural notes on the varieties advised?—AMATEUR CHRYSANTH.

5554.—**Liquid-manure.**—Could liquid-manure, which drains from a stall into a small pit be used to throw over the ground in the vegetable garden or on a field, or would it be too strong?—DUMFRIES.

5555.—**Flous elastica.**—Will someone kindly tell me whether the eye of this plant should I have a notch cut in them at the back of the bulb? Also the best time to cut old plants up for propagating?—O. K. B.

5556.—**Bulbs after flowering.**—I should be glad if someone would tell what is the best thing to do with my bulbs after they have done flowering? Should they be taken out of the ground?—A. B. C.

5557.—**Unsatisfactory Tomatoes.**—How is it my Tomatoes run all to wood? Should I nip the tops out? There is always plenty of bloom, but the fruit does not set. Is a gravelly soil good to plant in?—A. B. C.

5558.—**Best annuals for small gardens.**—I want to give some seeds to cottagers. Would someone please advise me as to what would be the best—say eight bright annuals? The gardens are small.—TULLYALLY.

5559.—**Stable manure.**—If 15 tons or 20 tons of straw are used in a stable in a year, what would be a fair price to charge for the manure, sorted by the purchaser who would take it the whole year round?—TULLYALLY.

5560.—**Cow-urine for Tomatoes.**—I have means of getting the weak of a byre, and want to know if it is suitable for Tomatoes? Also when it should be applied, and in what proportion should it be diluted with water?—J. K.

5561.—**Planting Irises, &c.**—Will someone kindly tell me if I can plant Irises this spring that will flower the same year, and the hardest kind to grow in a south-east border in a fairly light soil but cold climate?—A YORKSHIRE AMATEUR.

5562.—**Begonias (tuberous-rooted) from seed.**—Will someone kindly let me know the best way to raise these Begonias from seed, and, if heat is necessary, what amount of heat, and how long it is required?—FRANKY.

5563.—**Ostrowskia magnifica.**—I received two plants of this from a sale in London; they are about 1 inch long and as thick as a man's finger. Will anyone kindly inform me what kind of treatment they want, and if for greenhouse or outdoors?—M. K.

5564.—Ivy for a fence.—Will anyone tell me the best kind of ivy to plant covering a fence of posts and chains which I have along the edge of a drive? The posts are 2 feet 6 inches high, and the chains 8 feet long. Also where the plants are best procured?—A. F. B.

5565.—Treatment of a Crinum.—I have obtained a bulb of Crinum Kirkii from a nurseryman, and should be thankful for a few hints as to potting, what is the best soil, and how deep should the bulb be placed in the soil? Does it require much heat to start it?—THOMAS SOMER.

5566.—Maiden-hair Ferns, &c., in a room.—I should be glad to know if I can grow Maiden-hair Ferns in pots in a room, and also for a few suggestions for showy and hardy plants for an inside window-box in a fairly sunny room? Cold climate.—A. YORKHUISA AMATEUR.

5567.—Mushrooms for market.—Will someone kindly tell me if growing Mushrooms for market would pay? How would be a simple way to start on an allotment? Is it necessary to have manure-hills to grow them in? Would it do to place the spawn in the ground?—A. B. C.

5568.—Tomatoes from seed.—Will anyone be kind enough to tell me if I can raise Tomatoes from seed with the aid of an ordinary garden frame? I have a south-west wall to plant them out against. I have no greenhouse or hot-house. Also the best time to sow?—BUNOLKA.

5569.—Hardy Perennials.—I wish to plant a bed of these in a spot well sheltered from the north that would flower in succession all through the year in a mild climate. Will someone kindly give me a list of any useful showy perennials, giving month of blossoming and height of growth?—DUNKORTA.

5570.—Climbing Roses.—I have a dozen Climbing Roses in pots. They were bought with the intention of planting them out, but now are not wanted for that purpose. Would it be a good plan to give them a shift into some larger pots? They are in 24's now, and are good strong plants.—THOMAS SOMER.

5571.—Young fruit-trees.—I have some young fruit-trees trained to a wall, and should be glad if anyone would tell me: 1, How far back the main-stem should be cut to produce another tier of branches? 2, How should the side-branches be pruned to produce fruit-spurs for next year's bearing?—AMATEUR.

5572.—Artificial manures.—I grow in a small garden a few Strawberries and flowers. Convince me of the value of artificial manure. Which of the following is best? 1, Native Guano; 2, The New Guano; 3, Davis'; 4, Albert's. How and when should it be applied, and which is the best?—SIOGA.

5573.—Fertilising blooms of Tomatoes.—Does fertilising the blooms of Tomatoes increase the size of fruit? If so, when and how should it be done? Would going over the blooms with a camel's-hair-brush have any effect? Also, would thinning the bunches increase the total weight of crop or the reverse?—J. K.

5574.—Gas and electric light in a conservatory.—Will anyone kindly tell me if in a conservatory, 40 feet long, 16 feet broad, and 22 feet high, lit up occasionally during the winter months by four gas jets, or electric lights, would this light have any injurious effects on the plants in the building?—JOHN HOCOTON.

5575.—Treatment of Pear-trees.—My Pear-trees have a quantity of brown dust on them that comes through the cracks of the bark, evidently the work of some insect. What is the best remedy and time to employ it? How can I manure the roots of the trees? Some have Grass growing round the trees. Could I employ guano?—U.

5576.—Kitchen garden paths.—I am about to gravel my kitchen garden paths. Will any of your readers oblige me with some method of rendering them weed-proof? Would mixing tar with the gravel, and if so how, be the best? I can use any material for the purpose, but requires to be applied almost every year.—E. L.

5577.—Making a hot-bed, &c.—Will someone kindly tell me the best way of making a hot-bed, part stable-litter and part leaves? Will it be best to mix both together at time of making up the bed or to put a layer of each? Will not the beginning of March be early enough to start Cucumbers in a frame or on this hot-bed?—PANT.

5578.—Grubs eating Cabbage-plants.—Will anyone kindly tell me if the grub commonly called leather jacket, that eats the Cabbage-plants off at the base in the autumn, comes from a fly or a moth? Is there a good remedy for destroying the same? What is the scientific name of the grub and fly?—A. CONSTANT READER, Pangbourne.

5579.—Getting rid of Centipedes.—I want to know a remedy for getting rid of Centipedes and Millipedes? They are those things that get into the Strawberries and to the roots of vegetables, and have been found in the Celery. They do a great deal of harm in the garden. Soot and lime have been put on the ground.—E. F. L.

5580.—Cauliflowers dying off.—I frequently find after my Cauliflower-seedlings are up for a few days a black longitudinal speck appears on the stalk about the ground line, and in a day or two seedlings thus affected drop off. What is the cause of this, and how may it be prevented? My seed boxes are in a greenhouse heated by hot-water pipes. Would a dusting of sulphur do any good?—J. K.

5581.—Bishop's Weed.—There is a quantity of this troublesome weed growing in a plantation beside a Grass park; now it is spreading in through the Grass and killing it. What can I do to stop it? I should like, if possible, to leave it to grow under the trees, but to prevent it from spreading into the Grass park? I am afraid that putting anything on to kill it would kill the Grass too.—H. P. M.

5582.—An unheated greenhouse.—I have an unheated lean-to greenhouse, 12 feet long, 7 feet wide, 10 feet high at back, 6 feet front, with bed inside length of the house, 4 feet wide and 3 feet in depth. I propose growing Tomatoes and Roses. Would someone kindly oblige me with a list of courses that may be prevented? Position to be placed, &c. I get the sun all day.—POTTS.

5583.—Plants for a wall.—Would someone kindly suggest something suitable to cover a wall part gable about 6 feet long and the full height of my house? It has a southern aspect, and Tomatoes ripened there last year in

the open. I would like something that would look well in winter as well as summer as it is in full view from and adjacent dining-room window? Something quick growing (other than Ivy), would be preferred.—ZAZO.

5584.—Name of a plant.—I should be glad if anyone could tell me the name of a plant which I am anxious to get? I saw it growing in some public gardens at Dusseldorf. It has leaves like the Wistaria or large Laburnum-leaves. The flower is scarlet, shaped like a large Laburnum, but stands upright. The plant or shrub was about 2 feet to 3 feet high, and was planted out in beds in the open air. How is it grown and where can it be got?—C. L.

5585.—Growing Tomatoes.—Can I grow Tomatoes in a Cucurbit-house instead of Cucumbers? It is a span-roofed house, with a height of 3 feet above the hot-water pipes at the sides. Should I make up a bed over the pipes as for Cucumbers, or should they be grown in pots? If the latter is best, will not the heat from the pipes be too great? The pipes are 4-inch flow and return in the beds, and another pipe along the top of the path wall.—IGNORAMUS.

5586.—Roses in loak peat-soil.—I should feel obliged if anyone will let me know if I can grow a few Roses in a bed of this soil in front of my greenhouse? The bed is level with the garden, aspect south by west, sun on all day. It is 9 feet wide and 10 feet long. The soil has plenty of broken bones in it. There are 2 feet of soil and 13 inches of bricks for draining. I can get plenty of rotten horse-manure if of use. What would be the best Tea or other Roses that would suit the soil?—WILLIAM FINIAS.

5587.—Azaleas from seed.—I should be much obliged to "J. C. C." or anyone else, who will answer the following query. Having purchased a packet of seed of Azalea from a good seedman, it has since struck me that the plants may not come true from seeds. Are they in any way likely to be worth anything from a cut-idiom pack of view, or will they prove to be what any ordinary gardener would throw away? Any information respecting the same would be thankfully received.—LANCASTER.

5588.—Tomatoes in a lean-to house.—I have a house 20 feet long and 8 feet wide, 7 feet high at back, and 3 feet 6 inches in front, full south aspect, with 4-inch flow and return hot-water pipes close against the front wall and one end. Not staying. How many plants can I grow in it without crowding? I had thought of three rows, as I must leave a narrow path. How would that be? I am raising Blackwood Park, Hathaway's Excelsior, and Large Red. Out of these three, the north which would be the most prolific, as I want them for market?—INQUIRER.

5589.—Raising perennials.—I should be glad to know if I must raise the seeds of the following perennials in pans indoors? If so, could I do so in a short passage which connects two sitting-rooms, and has a low glass roof facing west? At present it only gets a very little sun. I should much prefer sowing them outdoors if they would succeed. The seeds are: Anthericum, Aquilegia, Campanula grandiflora, Chelone, Dorianicum, Galbaria, Geranium, Phlox, Potentilla, Prunella, Papaver nivalicaule, and Phlox (herbaceous).—FRANK CRANER.

5590.—Peach-growing.—Will someone be good enough to inform me which varieties of Peaches and Nectarines are best to be grown under glass with heat at the seaside (Southport, Lancashire)? I desire rather those which are most certain of producing a good average crop, and of good flavour; size of fruit less important than the above qualities. I propose erecting a three-quarter span-roofed house to grow them in, divided by a partition. Situation due north. What height should the back wall be made, and what width should the house be?—ENQUIRE.

5591.—Growing Melons in a vinery.—I have a vinery (containing nine Vines) 12 yards by 8 yards, a long roof facing south, short roof to north, old-fashioned brick flue, an inside border, 3 feet wide, Vines planted inside, roots running out also. I have grown Cucumbers with great success for several years, running them upon the single stems between the Vines. This year I have made a Cucurbit-house. Will someone kindly tell me if I can grow Melons with Great Easterns, and what variety for the situation, and at what stage of the Vines should I start the Melons?—GIBBERIA AMATEUR.

5592.—Flowering creepers.—Will anyone tell me the best flowering creepers to cover the trunks of two old Laburnum-trees which are growing at one side of a lawn in front of the house? I do not wish to cut them down, but the trunks are quite bare and very unalightly, although there is a great deal of bloom on the upper part of the trees, which overhang a wall. It would like about six plants, as the trees divide into arms about 2 feet from the ground. Could I have different kinds of creepers which would give bloom all through the year, or bloom in summer and foliage and berries in winter?—IGNORAMUS.

5593.—Growing flowers in town.—I shall be thankful to anyone who will kindly instruct me how to grow some nice flowers in a town in the yard? I have a place 3 yards long by 2 yards wide; the soil is very poor. Shall I put lime on it before I dig it up in till the worms, or shall I dig it up first, and then put the lime on it? Again, the stable-manure is mostly long straw. How shall I manage it, as I cannot dig it into the ground? Now suppose I put the lime on, and then put the manure on the top of the lime and then both remain for a time? Say how long it should remain on before I put my plants or seed in?—NOVIC.

5594.—Plants, &c., in a greenhouse.—I am erecting a greenhouse 25 feet by 9 feet, with a division at 12 feet. It will be heated with a boiler, and two rows of 4-inch pipes down the side. Would it be advisable to plant a Vine in one division—a Black Hamburgh? If so, when should it be planted? Should it be in a pot or planted in the ground? In the other half I purpose growing a Marechal Niel Rose. What can I also grow in each of these divisions?—Addition?—Vines, Ferns, Azaleas, Fuchsias, Carnations, Primulas, Lilies, "Geraniums," Heliotropes, Spiraeas, Genistas, Chrysanthemums, Tomatoes, and any other showy plants.—TRAO.

5595.—Planting Apple-trees, &c.—I have a garden and some five-year-old Apple-trees transplanted by myself, and cut off all roots 2 feet from the stem, and in

replanting has trod the earth tight round and above the roots. Would someone kindly inform me if this was right procedure, and if not what I had better do? The soil is light and warm. Would it not be well in the case of fruit-trees to slope the soil down to the trunk—say, from 2 feet to 3 feet away, so that they would stand in a kind of shallow basin? And after severe root-pruning, should not a corresponding amount of loam be removed? My trees are vigorous growers, and are promising well for fruit this year.—J. E. H.

5596.—Chinese Lilies.—Last November I had two of these bulbs given to me, and put them, according to directions, in a bowl of water with stones at the bottom. I placed the bowl on a table in a sunny window in the dining-room, where they grew well, some twenty or twenty-five high buds appearing, and growing 18 inches high, when suddenly, about December 25th, the larger ones began to look brown at the tops, and finally died up altogether, their stems keeping quite green. Each bud on the bulbs died in the same way, not one bursting the sheath, although the leaves and roots are as strong and healthy as possible. Can anyone tell me the cause and what to do to avoid such disappointment again?—G. E. COX.

5597.—Use of a propagator.—Having made a propagator on the lines suggested by "J. C. C.," I shall be glad if he or some other correspondent will give me a few hints as to how best to use it for producing flowers for outside growing? I have now in it some of last autumn's "Geranium" cuttings, which have just kept alive, having been in pots at a sunny window, and they do not seem to like the treatment, the edges of the leaves turning black. Is this from the steam? I want now to grow from seed Lobelia, Feverfew, Verbenas, Phlox Drummondii, and Sweet Peas. Should I sow in pots or boxes? How long should the lamp burning night and day? Will the same temperature suit them all? I find that the Cocoa-nut-dire soon gets to a good heat, and also when the lamp is out it very quickly gets cold.—IGNORAMUS.

5598.—Eversgreen hedges.—Two or three weeks ago there was an interesting article in the Standard on evergreen hedges for shelter, written by "J. C. C." or "J. Groom, Tottenham." I have a large kitchen garden, facing south, good soil (loam over chalk), but much swept by the S.W. winds prevailing on the E. coast. It is surrounded by a high Thorn hedge, getting thin at the bottom, and I want to plant evergreens inside to act as shelter from the wind without cutting down the Thorn hedge. When should they be planted? Is not the end of April or May the best time to plant? Lay the same ground as the original, Currants, Lawsons, and Hollies? And how near the hedge may they be put? I shall be grateful for an answer from one who has had experience. The soil is rich, but gets very dry in summer.—DORSET.

5599.—Plants for a border.—I wish the borders of a long walk up the centre of my garden to be planted with as far as possible permanent plants. The garden is used for growing vegetables, but is much exposed to view. Would Roses pegged down do, and if so, would someone kindly give me the names of about twenty-four Roses which, if possible, would give me bloom during spring, summer, and autumn, both for the garden and for use and for nice appearances outside? Would it be well to have a few tall plants planted at the back of the Roses, and, if so, please give me the names of a few to mix with them—some Gladioli and Dahlias which I have? I should like some tall Lilies, if they would suit, and perhaps you would tell me some others? How far should the Roses be planted apart, and should there be plenty of manure put to them when being planted?—IGNORAMUS.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5600.—Culture of Orchid (Paziled).—You should get the "Orchid-growers' Manual," published by H. S. Williams & Son. In it you will find all you require.—M. B.

5601.—Blechnum brazeiliense (J. Richardson).—Yes; this plant requires shade, and it likes an abundance of water and a warm temperature. Treated in this manner it should retain its fronds well; but it should not be kept without air.—J. J.

5602.—Broken Orchid-roots (R. B.).—Yes; the plants are injured by the breaking of roots, so avoid this as far as possible; but, if only one or two are broken no perceptible harm occurs. Sand, if used properly, is good in most instances.—M. B.

5603.—Vanda Kimballiana.—Want to know: 1, What is the best temperature to keep this plant in? I do not succeed with it at all well, and it is such a gem when in flower, that I am not at all satisfied. What should I do to get it to grow in the Odontoglossum-house, or at all there I saw it doing better than I have seen it well.—M. B.

5604.—Leptotes bicolor (E. M. C.).—This is the name of the very pretty flower which you send. It requires to be grown in the cool-house, and treated in the same manner as Sophronites grandiflora, which see on another page. I know of only one species, but it is sometimes called L. scutellaria, but I have seen a worthless Pleuroballia, P. lineata, sold for it.—M. B.

5605.—Odontoglossum Halli.—D. G. sends me a very fine flower of this species, named O. Harryannum, which is evidently a mistake, the above being its right name. It is a very cool species coming from considerable elevations on the Andes, and it thrives very much better when grown in colour. There are many varieties for which one may be particularly good.—M. B.

5606.—Diplazium plantagineum (H. Harris).—This is a very deep-green simple-fringed Fern of great beauty, and the cause of the so-called turning brown is a surplusage of water in some form or other, for which I think you have gone in your case from bad drainage. You say you have not used the syringe since last November, so that should imagine the drainage has become clogged. See to this and set matters right.—J. J.

5007.—*Epigaea repens* (T. J. M.).—From what you say and from the piece sent I should say this is the name of your plant. I should advise you to plant it in the Rhododendron bed, where you will find it spread well and repay you by the production of a vast quantity of its well-shaped flowers. Under the Rhododendron it does well in summer, as it is a plant that likes to be in the shade and to be kept cool. —J. J.

5008.—*Saxifraga oppositifolia*.—G. Devon sends a nice specimen of this lovely plant, which is very early for it; but I suppose in his part of the country it has been very mild, and so that such plants are forward. I have in my London garden *Saxifragas* and *Crocus* in bloom, and they have been for a week or two, and hope soon to have the pleasure of seeing some nice gatherings from my country readers of various hardy flowers. —J. J.

5009.—*Onoclidium pubes* (H. Allen).—This is a plant that used to be more frequently brought from Rio than it has been during the past few years; but, coming from the Organ Mountains I suppose it was one of the convenient species to get at. But it is not worth your growing, and there are plenty of other kinds in the neighbourhood that produce showy flowers. I would advise you to write to your friend and ask him to send you such. Ask him to see them flowering before sending them, and in this way you will get something worth growing. —M. B.

5010.—*Loelia superbens*.—M. Lindsay asks in this plant a fine thing? She says a large plant is offered her cheap, the owner assuring her that it is a very fine thing. Yes, and so it is; but "M. L." has not ample space she will be bothered with the plant, and I may add, fine as it is, this is a species I should not recommend any small grower to take up with, its size being quite out of proportion to a small place, the flower-spikes alone growing from 1 yard to 8 yards in length. Try some smaller species, "Miss Lindsay," and you will be better pleased with the result. —M. B.

5011.—Garden seedling of the genus *Vanda* (H. T.).—There has been but one of this family raised, and it is a cross between *Vanda teres* and *V. hookeriana*, which was obtained at Singapore, where both species are commonly cultivated, and it was named in honour of its raiser, Miss Jouque. It is said to be a very handsome variety, and I long to see it in English collections. No other has yet been raised, I believe; and we shall have some new *Vanillas* added to the now numerous hybrids raised at home by some of our gardeners. I do not know if my friend Mr. Seelen has any seedlings of this genus yet? —M. B.

5012.—Potting Orchids (An Anxious One).—Do not begin this operation yet for a week or two, but devote the time to the preparation of material—picking the grass and weeds out of the *Sphagnum*, in picking the peat-fibre, washing the crocks for drainage and the pots, which may all be done beforehand, and you will find the advantage when you come to the potting or re-potting. In the case of a plant or plants being absolutely in want of repotting it may be done, but I would advise the month to be allowed to be reckoned amongst the past before the general repotting is undertaken, and that will be soon now. —M. B.

5013.—The British Maiden-hair Fern (*Adiantum Capillus-Veneris*) (M. J.).—This cannot be said to be generally hardy, and you have not found it growing wild in Surrey, for too far you sent me to meet the Maiden-hair Fern, but one of the plants called the Black Maiden-hair (*Adiantum Adiantum-nigrum*), which is one of the most robust of the family. The gardener who named it for you was wrong, or you have mistaken him. I have never seen the true Maiden-hair Fern left in the open but one near London; this was in the form of an escaped seedling that had established itself on a low wall; but it was in a well-sheltered place. This plant lives and grows for years, but I think the severe winter of 1891 killed it. —J. J.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to names should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, W.C.

Names of plants.—*M. U.*—1, *Blechnum occidentale*; 2, *Cyrtium bialeatum*; 3, *A. Propitica*; 4, *Polystichum cristatum variegatum*; 5, *Pellia aiantoides*. —*W. Dalrymple*.—*Loelia* among *Saxifragas*; good variety. —*J. Midway*.—1, *Cyrtium Fortunei*; 2, *Asplenium furcatum*; 3, *Adiantum asiaticum*; 4, *A. Selaginella*, sent again better specimen. —*J. Richardson*.—1, *Blechnum brasiliense*; 2, *Pteris tremula*; 3, *Pteris longifolium*; 4, *Asplenium bulbiferum*; 5, *Loelia* like *Asplenium adiantoides*; 6, *Adiantum amabile*; 7, *Adiantum mundulum*; 8, *Adiantum speciosum*; 9, *Jasiumum* sp.; 10, *Selaginella celsa*; 11, *Selaginella stolonifera*; 12, *Selaginella pubescens*; 13, *Antericum variegatum*; 14, Cannot name from leaves only. Do not send so many at one time again. —*T. M. R., Devon*.—*Echeveria rotunda*.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name fruit sent in as a time, and these only when the above directions are observed. Unpaid parcels will be refused. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of fruit.—*Southcot*.—Apples: Probably *Winter Queening*, but we cannot say for certain, as they were in bad condition, made worse by being packed in wet Moss. —*Henry Biens*.—Apples: Probably *Norfolk Beefing*, but we cannot name accurately from a single fruit.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

C. B.—*Cinerarias*. Apply to Messrs J. & A. Hayes, The Nurseries, Edlington, London, N.—*Dryas*. Apply to Messrs. J. & A. Hayes, The Nurseries, Edlington, London, N.—*Wax*. See page 710.

Tottenham, London, N.—R. Beeston, Preston.—Apply to Mr. B. C. Ravenscroft, Hild-wood, near Crawley, Sussex.

Catalogues received.—*Seeds and Plants.*—Mr Wilhelm Filzer, 74, Millstrasse, Stuttgart.—*Farm Seeds.*—Messrs. F. Webb & Sons, Woking, Stourbridge, Staffs. —*Farmer's Year Book.*—Messrs. Sutton & Sons, Reading, Berkshire. —*Vegetable and Flower Seeds.*—Mr. Eric F. Suss, Maidenhead, Berkshire.—*Seeds for the Garden.*—Messrs. Albert Morris & Co., 140, Tullow-street, Carlou, Ireland.—*Farm Seeds.*—Messrs. Toogood & Sons, Southampton.

Books received.—"Tree Pruning," by A. Des Cars, and "Practical Forestry," by A. D. Webster.—Messrs. Wm. Rider & Son, Limited, 14, Bartholomew-close, London, E.C.

BIRDS.

5407.—Management of a Parrot.—In answer to "Pollie's" question I beg to tell her that my bird pulled out her feathers in the same way, and I got her cured of it. I syringed her every day with a decoction of Quassia— $\frac{1}{2}$ oz. of Quassia-chips to a pint of boiling water—and let it stand for an hour. This soon stopped her picking out her feathers, and I think did her health good, too. During this treatment the bird must be strictly dieted. I give my bird a little Hemp-seed and Indian Corn, along with the Canary-seed and bread and milk, but the milk must be boiled, and no meat or bones of any kind. I was in the habit of sometimes giving my Parrot bread dipped in soup, and I always blamed that for making her pick out her feathers.—SNAP.

FERNS A Speciality.

We have the finest, most varied, and interesting Trade Collection of Ferns in the world. Over 1,000 different kinds of Ferns, Greenhouse and Wild Ferns, and over 600 kinds of Hardy Ferns. Every Fern should have our 111-Page ILLUSTRATED CATALOGUE (No. 22) the best ever published. It contains 100 Illustrations, and a large amount of valuable information, price 2s., post free. We send our smaller partially descriptive Catalogue free on application. We now offer 13 beautiful kinds of Stove and Greenhouse Ferns for 3s.; 25 varieties for 3s. 6d.; 50 for 5s.; 100, in 12 varieties, 7s.; 100 in 25 varieties, 10s.; 100 to 50 varieties, 13s.; 100 different kinds, 15s. Hardy Ferns, 12 varieties for 3s.; 21 for 5s. 6d.; 50 for 7s.; 100, in 12 varieties, 11s.; 100 in 25 varieties, 13s.; 100 in 50 varieties, 15s. All nice plants.

W. & J. BIRKENHEAD, F.R.H.S., FERN NURSERIES, SALE, NEAR MANCHESTER.

1,000 REGAL AND SHOW CHOICE Named *Pelargonium*.—Vigorous bushy plants to make good specimens for summer bloom, including such grand varieties as *Alfred Russel*, *Mabel*, *Volante*, *Nationalis*, and many others equally distinct and good. 3s. 6d. per doz. Cash with order. 2 small double Ivy-leaved gerania with each doz. Satisfaction guaranteed.—J. W. COLE, Florist, Midland-road, Peterborough. Testimonial: "Plants received this morning give every satisfaction."—B. T. Hackett."

18 PACKETS CHOICE HARDY FLOWER Seeds, post free, 1s. 3d. A very special offer.—BRADLEY BROTHERS, Barnley, Lincoln.

WELCH'S SEEDS.—*Dahlia*, *Pelargonium*, *Fuchsia*, *Hardy Perennials*, &c. Catalogue now ready, post free.—WILLIAM WELCH, Romford, Essex.

TOMATO VICTORY is an immense cropper of firm, medium-sized smooth fruit. Those wishing for an early profitable crop should write to the 6d. or 1s. pkt.—WILLIAM WELCH, Romford, Essex.

GERANIUMS, autumn rooted cuttings.—*Scarlet Veil*, 1s. 3d. doz.; 7s. 6d. 100. *Madame de la Motte* (pink) and *White Veil*, 1s. 3d. doz.; 7s. 6d. 100. *Flower of Spring*, 1s. 3d.; 10s. 100. *Crystal Palace* (Gem), 1s. 10d. doz.; 11s. 100. *Henry Jacoby* (dark-rose), *Perilla* (bronz), 5s. doz.; 12s. 100. Post free for each.—JAMES BARTON, Northbridge-street, Rochester, Kent.

CHRYSANTHEMUMS.—*Beauty of Exmouth*, Mrs. Noyditt, Lord Brooke, and *White Plume*, 6d. each. Others at 2s. 6d. doz. Late free. Telegraphical Rochford Cup-cumler seeds, 6d. doz.—J. B. RIDING, Nurseries, Chingford.

VINES, 3 years old.—33 Hamburgs and 50 Alicante, in the sold cheaply to immediate purchaser.—R. COPELAND, Breeding, Sussex.

NEW PRIZE CHRYSANTHEMUM Plants.—W. Seward, Mrs. Bruce, Fintley, Lizzie Seward, C. Shrimpton, Mrs. Payne, Princess Victoria, President Borel, B. Emouth, Dorothy Shea, Charles Ellick, Golden Viviani Morel, and *Mollie*, Theresa Key, extra grand, the 12 plants, 6s. free.—W. FOX, Chrysanthemum Grower, Banbury.

DEVERILL'S PEDGREE ONIONS.—For particulars how to grow them send for Deverill's Seed List. Royal Oxfordshire Seed Establishment, Banbury.

GOOD KING HENRY (Mercury).—The grandest vegetable in cultivation. Plant at once, 49 roots, 2s. 6d. free. T. HALL, 61, Stoney-avenue, Scarborough.

SURPLUS PLANTS.—6 *Bridal Wreaths*, 4 *Gloxinias*, 4 *Begonias*, 2 *Genetas*, 2 *Arums*, 2 *Araucarias*, 1 *Spermatum*, 4 *Marguerites*, 4 *P. obtusica*, 4 *Fichtas*, 4 *Geraniums*, 4 *Ivy-leaf*, 3 *Ferns*, 2 *Coronillas*, 2 *Scarlet Tropeolum*, 2 *Cacti*, 4 *Isoplepis*; 54 plants, 4s. 6d. free. 1 fine Palm and a lovely new Greenhouse Climber gratis with each order.—HEAD GARDENER, 48, Warwick-road, Banbury.

New Deep Golden-yellow Ostrich Plume CHRYSANTHEMUM W. A. MANDA, large, strong constitution, 40 foliage dwarf, free flowering, grand decoration, strong cuttings, 9s.; 3s. 6d., in box, free. Mixed cuttings, grand exhibition sorts for decoration, border or table work for cutting from, strong grown, 50, 2s. 6d., free. T. HALL, Tetumouth, Devon.

SEEDS. SEEDS.

Unrivalled in Quality and Price.

Study your pockets and write for my Catalogue of Genuine Seeds, at half the usual price.

CARNATIONS A SPECIALITY. Strong well-rooted layers. No rubbish. Alice Ayres, 7d. Comet, 8d. Germania, 6d. Old Clove, 6d. Mary Morris, 7d. Frank Walter, 8d. Ruby, 6d. Rose Celestial, 1d. Winter Cheer, 6d. La Neige, 6d. Reynolds Hole, 8d. Gloire de Nancy, 6d.

1 of each of the above, 5s. 6d., free.

CUCUMBER PLANTS. Improved Telegraph, strong and healthy. The same as those which gave so much satisfaction last season, 3 for 1s.; 3s. per dozen, free.

TOMATO PLANTS. Best varieties, transplanted, 12 for 1s., free; 5s. per 100.

STRAWBERRY PLANTS. John Ruskin, the best early variety, 3s. 100; 15s. 1,000, free.

SATISFACTION GUARANTEED.

THOMAS H. COLEMAN, Safron Walden.

WHINHAM'S

Industry Gooseberry.

THE EARLIEST AND MOST PRODUCTIVE GOOSEBERRY IN CULTIVATION.

Good Strong Bushes, 4s. doz., 20s. per 100, free.

THOMAS COLEMAN, Safron Walden.

ROOTED CUTTINGS.—*Chrysanthemums*, *Phloxes*, and *Marguerites*, 1s. 3d. doz. *Kempner Williams*, *India*, 2s. 6d. 100, carriage free.—G. MAZZLETT, Heath Nursery, Worcester.

CUCUMBERS (Massey's Champion), the finest grown; will produce fruit 74 lb., long and 4 1/2 weight. Growers will do well to give it a trial. 12 seeds, 1s.—H. MASSEY, Nurseries, Bate, Cheshire.

BOYCE'S CHRYSANTHEMUMS (1,150 vars.).—Many thousands of well-rooted cuttings, 2s. doz.; 15s. 100. Catalogue with complete cultural directions, 4d. (returned in first order).—W. E. BOYCE, Archway-road, Highgate, N.

BOYCE'S EARLY-FLOWERING MUMS, bloom outdoors from July till October. Ready in March a splendid collection of autumn plants, correctly named, 2s. doz., 5s. for 5s. (sent abroad).

BEAUCHY'S CHRYSANTHEMUMS.—Best price-winning varieties, old, 3s. 2d.; new, 6s. dozen plants. Outcings, half, truly named.—Kingswell, Devon.

BEAUCHY'S FIRST PRIZE BIGNONIAS.—Tubers, 1st class, selected Giant *King*, marked to colour, yellow, white to dark crimson, all different, 7s. 6d.; 2nd size, 5s. 12 mixed, fine quality, 3s. 6d. 12 superb double 10s., 15s., 30s., 42s., according to quality. Seed, grand single 1s., 1s. 6d., 2s. 6d. Mixed double and single, 2s. 6d., 3s. 6d. *Gloxinias*, finest strains, 6s. dozen.—BEAUCHY & CO., Kingswell, Devon.

SHEPARD'S *Houma*, *Lilias*, *Begonias*, *Staphelias*, *Azucenas*, *Chrysanths*, *Roses*, *Carnations*, *Pansies*, &c., at reasonable prices. Catalogue gratis and post free.—W. & A. SHEPARD, Hunslow, Middlesex.

A MURKLOUS VITICOLA, 4, 1s. 3d.; *Wistaria*, 3 for 1s. 6d.; *Bignonia radicans*, 4, 1s. 2d.; *Climbing Rose*, 4, 1s. 2d. All good strong plants, all free.—HENRY & CO., near American, Bucks.

GARDENIAS.—Specimen plants, thickly budded, 6s. each. *Faucaria rotunda*, splendid specimen in 9 in. pots, 4s. each. Packing free.—F. KNIGHT GAMES, Fulwell Nursery, Twickenham.

GERANIUM CUTTINGS.—Queen of Belgians, well-rooted, from stores, 1s. 6d. per dozen. *Marguerite* cuttings, yellow, 1s. 6d. per 100. Carriage paid.—F. KNIGHT GAMES, Fulwell Nursery, Twickenham.

EARLY TOMATO PLANTS.—*Huckwood* Park Improved, Sutton's Perfection (the latter strongly recommended by many testimonials from last season), 6 to 8-inch plants, sent free, 2s. per dozen. *White Marguerites*, large plants to flower in April. Sent free, 3s. 6d. per dozen.—HEAD GARDENER, Thundersley House, Thundersley, Essex.

LILY VALLEY.—Strong crowns, 1s. 3d. 100; 2s. 3d. 200. *Pyrethrum* (Moll) *Blanc*, D. white hardy, 2s. 6d. dozen.—OSWICK, Barnham, Bedford.

RICHARDIA "LITTLE GEM" true, 5s. per 100 single pots, post free. Cash.—THOMAS ROGERS, Nurseries, Loddwold, Leicestershire.

GRAND GREENHOUSE COLLECTION.—Orchid, *Panacraum*, *Aspidistra*, *Hoya*, *Staphelia*, *Fan-lana*, *Colous*, *Asparagus*, *Isoplepis*, *Cyperus*, and 2 *Ferns*, the lot, 3s. 6d. free.—HASKINS, Ormiston, E.R.D., Glas.

TO EXHIBITORS and others wishing to excel.—An Anglo-Spanish Onion Seed, saved from raiser's stock. Has been awarded a Gold Medal, 1,000 seeds, 1s., free.—LINDREY, Frome.

FIRST PRIZE DAHLIAS.—First Bath, F. Trowbridge, etc. 12 distinct Show Dahlias, 4s. 12 distinct Cuttings Dahlias, 4s. 12 beautiful Pompon Dahlias, 4s.; for 2s. Dahlias, 6d. 100. All true to name, carriage paid.—LINDSEY, Dahlia Grower, Frome.

GESNERA ZEBRINA DISCOLOR.—For Sale a few bulbs just ready to be started from magnificent plants over 3 feet high. Large, 12s. per dozen; smaller, 6s. to 8s. per dozen.—THE GARDENER, Stanwell House, Stanwell, Middlesex.

ACHIMENES, large flowering roots, blue or mauve, 1s., and *Chrysanthemum* cuttings, leading varieties, 6d. per doz., free.—ELLIS, Wadobridge, Cornwall.

GRAPE VINES.—Fine fruiting canes in pots, 10s. 6d. 100 or 15s. bunches at once, 6s. 6d. each; 3s. for 6. Car. pd. on 6. All Fruit Trees wholesale and retail.—WILL TAYLER, Nurseries, Hampton, Middlesex.

ROSES.

MILDEW ON ROSES.

Now that young growth upon indoor Roses is fast becoming general, we shall soon have many suffering from attacks of this dreaded disease. As there is so little doubt respecting its chief causes, it may be well to devote a small space to its consideration, with the object of taking precautionary measures in due time. Carelessness in ventilation and watering are undoubtedly responsible for most of the severe attacks of mildew so destructive to Roses under glass. I also incline to the opinion that many varieties are far more subject to its attacks than others, although under similar conditions. Her Majesty, Innocente Pirola, and Edith Gifford invariably take it earliest with me, nor does it matter if they be under glass or in the open air. I have a plant of Innocente Pirola turned out into a border where it would seem impossible for draughts to reach, and yet if there are any spots of this disease upon a plant some yards off, it seems immediately communicated to I. Pirola as well. We cannot steer clear of mildew without patient care and more or less command over the atmospheric conditions of our houses. Sudden changes, of whatever nature, have much to do with disastrous attacks from this pest, and it is the same indoors or out. We find it during a wet, and also during a dry season. A hot or cold season with sudden changes also gives us serious attacks of mildew. Any check to growth, whether arising from a chill in the atmosphere or a sudden access of heat, or from either extreme in watering, the results seem the same. We see, therefore, that it is necessary to be very careful about these points if we are to steer clear of mildew. As the season advances and we are favoured with finer weather and more sun, there will often be times when the temperature under glass rises rapidly. Too often the admission of a little air, or rather the steady outlet of the overheated atmosphere, is not commenced in time, and is, consequently, hurried mainly a little later on. This will not do if we are to have healthy growth clear from mildew. Whenever it appears likely to be bright enough to make any appreciable difference to the atmosphere of a house, we must take the precaution of

CHECKING THE ARTIFICIAL HEAT at once. This the more necessary because it so often happens that bright weather early in the year is accompanied by a keen wind, thus rendering it even more difficult to admit air. An arid atmosphere closely following one of a humid nature will also have much effect upon the attack and spread of mildew. It is the want of a little consideration in ventilating and watering which is responsible for many of the failures and disappointments occasioned by this pest in the culture of Roses, and I cannot direct too much attention to these little details. We all agree that prevention is better than cure; then why not devote more attentive thought to the former? One will labour in the most assiduous manner to battle against mildew after it has

gained a strong hold upon the plants; but how much more satisfactory had a tithe of this care been expended earlier. All rosarians have experienced the exceeding disappointment of suddenly discovering mildew upon what was a few hours before a healthy lot of plants, and unless immediate measures be taken to remedy the cause and check its spread, the whole season's crop is almost a dead loss. But I will leave this and go on to a description of some remedies which I have found most effectual, and from the use of which I am happy to say we have not had a serious attack of mildew under glass for many years; of course, there has been due attention accorded to its avoidance in other ways—at least, so far as young assistants can be persuaded to carry out. The earlier any remedy is applied the more effectual it is likely to be. I find

SOFT-SOAP AND SULPHUR, with a dash of paraffin, the cheapest; but any insecticide may be rendered more deadly to mildew if a little extra flowers of sulphur are added. When the whole is kept well stirred during application, an almost imperceptible dusting is left upon the foliage. Quicklime and sulphur are also very efficacious. I have mixed it in this way: A little unslaked lime is placed in a pail, just sufficient water added to slake it, and while hot the flower of sulphur is dropped into it. Before it becomes quiescent fill up this pail with water, and dilute the liquor after the whole has settled down. A third remedy is a quarter of an ounce of sulphide of potassium to a gallon of water; but my preference goes to the small addition of sulphur to a weak solution of any tried insecticide. By rectifying the cause and applying these remedies at once we can fight against mildew successfully; but nothing will avail to the same extent if neglected for many hours after the attack is noticed. P. U.

5570.—Climbing Roses.—If the varieties of Roses are worth the trouble that they will involve if grown in pots altogether they may be shifted into larger pots with advantage, but it all depends upon what they are and the convenience you have for growing them. If they are hardy sorts, you may plunge the pots in the ground by the side of a walk, and train the growth on sticks or wires. Why not plant them out, and form pillars or bows by the side, or over a walk in the garden? We see too few pillar Roses, yet they are very easily managed, and it is a phase of gardening that everyone admires.—J. C. C.

—“Troublesome” could not do better than to carefully shift these into larger pots as he proposes. A 24 size is not large enough to support the growth and bloom of a strong climber, and they seldom prove satisfactory unless potted on. I am aware that many do not approve of any root disturbance until a crop of bloom has been secured; but over twenty years' experience has resulted in my invariably potting before forcing, care being taken to disturb the roots as little as possible.—P. U.

5571.—Roses in a black peat soil.—The soil is not the best that could be selected, at the same time I do not see why good hardy

Perpetual Roses should not do fairly well in it. I think you might improve it by the addition of about four barrow-loads of coarse sand or grit spread on the surface and forked in before planting. Select dwarf plants and put three rows in a width of 9 feet. You may dress the soil before planting with three barrow-loads of rotten manure, but after that use it sparingly, as too much manure has a tendency to make such a soil sour. Judging from the information you send, I am afraid the ground is not dry enough below for Tea Roses to be reliable.—J. C. C.

—You have got much more drainage than is necessary unless your soil around is very moist. I should confine myself to the China and Tea for such a soil and aspect. At present I should not manure it, letting the plants feel their way and feed upon the bone you have added. In a couple of seasons, if they thrive well, you could give the stable-manure to advantage.—P. U.

5593.—Growing flowers in town.—The German Irises are splendid town flowers, and read the replies to the correspondent who inquires about the best kinds to grow. Hints are there given, not only as regards culture, but also varieties. The Carnation is also useful, the Old Clove especially. This fine flower is very easily grown in a good, light soil, and readily propagated by layers, which should be made the last week in July. It consists in selecting the shoots of approved varieties that is desired to increase, and removing the soil from around the plant to about 24 inches in depth, filling up the hollow with light sandy compost prepared specially for the purpose. Take each shoot separately, hauling it with care to prevent severing it from the parent, and removing the leaves until within about five joints of the top. A sharp knife is now necessary to cut half through a joint, but taking care not to sever the shoot; then with a wooden peg, formed of a twig of a branch, make the shoot firm to the soil, and with this tongue in the prepared compost to promote quick rooting. The whole business is very simple and readily acquired. Cover the pegged-down portion with the prepared soil and water carefully. The time required for rooting is about a month, so that it will be in late August or early September before the layers can be removed from the parent and planted out. You can plant Carnations and Pinks now, also Anemons japonica, Tufted Pansies in variety, Michaelmas Daisies for the autumn, Philoxera for August, Campanulus, Delphiniums, Duroniens, and such things as Selam spectabile. But your place seems very small. Thoroughly dig it up at once, incorporate lime with it, manure it, and plant only those things mentioned and hardy Ferns, forms of Male and Lady Ferns, London Pride, Creeping Jenny, a Carnation or two, Campanula latifolia, which I have found to do very well, and a clump or two of German Iris.—C. T.

5584.—Liquid-manure.—The liquid which drains from a stable may be used for any garden or field crop. Dilute it with water according to its strength and the purpose for which it is used. For most purposes, when applied to growing crops, it might be diluted with three times its bulk of plain water.—E. H.

5589.—Cow-urine for Tomatoes.—Yes, this will form a very suitable enrichment for Tomatoes. Dilute it with a gallon of water.—J. C. C.

GARDEN WORK.

Conservatory.

Callas (Arum Lilies) make very striking groups in the conservatory... Callas reproduce themselves quite true to type from seeds... There is a small flowered variety of Calla, the blossoms of which are useful for cutting...

Forcing-house.

To keep up a succession of flowers it will be necessary to introduce from cool-houses or pits relays of suitable plants, which have been specially prepared for forcing... There are many thousands of poor, weakly, badly-ripened crows imported which never can give satisfaction...

Stove.

Take off cuttings of the young shoots of Poinsettias, Euphorbias, Gardenias, and other plants when of suitable length... Take off cuttings of the young shoots of Poinsettias, Euphorbias, Gardenias, and other plants when of suitable length...

Ferns under glass.

Loss of time now in potting any plants which require fresh soil... Some may require a good part of the old soil shaken away, and such plants may have clean pots of the same size...

all, but it is always safer and better to put sufficient drainage for the water to pass freely away.

Gold Frames.

These will be found very useful now for many plants in pots which have gone out in the conservatory... These will be found very useful now for many plants in pots which have gone out in the conservatory...

Hot-bed making.

even in backward districts, should have attention now, and even a small hot-bed, made in a trench, and covered with 6 inches or 8 inches of soil, and a rough frame placed over it will be useful for many purposes...

Window Gardening.

Windows are bright now with Laffodils, Hyacinths, Freesias, and other bulbs, which can be brought on without forcing, and these bulbs, if taken care of, may flower again next year... Windows are bright now with Laffodils, Hyacinths, Freesias, and other bulbs...

Outdoor Garden.

Mossy lawns may be dealt with now. If the lawn is small, scarcely if at all, it will be best to use a hand rake, the work may be shortened much by using a short-tined harrow to loosen the Moss first... Mossy lawns may be dealt with now. If the lawn is small, scarcely if at all, it will be best to use a hand rake...

Fruit Garden.

Corner Apricot and Peach-trees as they come into blossom. The amount of covering used must depend upon the situation of the garden, its climate, and natural shelter... Vegetable Garden.

The Onions should be sown at once, if not already in. The first week in March is early enough for cold, heavy land, but the Onion crop should be got in in February in light land, especially where the maggets are troublesome... The Onions should be sown at once, if not already in. The first week in March is early enough for cold, heavy land...

making a few large rough labels on some wet day, and writing the name of each crop on separate labels, and driving them in the ground where the things are to be sown... making a few large rough labels on some wet day, and writing the name of each crop on separate labels...

Work in the Town Garden.

The days are growing appreciably in length now, and things under glass are beginning to move in earnest... Yesterday and to-day the sun has been quite hot here, and warm water has been required than for months past... The days are growing appreciably in length now, and things under glass are beginning to move in earnest...

THE COMING WEEK'S WORK.

Extracts from a Garden Diary from February 24th to March 3rd.

Finished nothing up Peaches, Apricots, and Nectarines on walls, for the protection of the blossoms... Finished nothing up Peaches, Apricots, and Nectarines on walls, for the protection of the blossoms. A double thickness of fishing-net has been used, and this system has been found efficient for many years past...

* In cold or northern districts the operations referred to under "Garden Work" may be done from 10 days to a fortnight later than is here indicated, and equally good results.

TREES AND SHRUBS.

A BEAUTIFUL SHRUB.

ZENOBIA SPECIOSA PULVERULENTA.

A GLANCE at the accompanying cut, which faithfully represents a flowering spray of this lovely shrub, will be sufficient to prove it one of the most charming of all garden plants cultivated in the open air in Britain. When treated as a pot plant and kept clear of hard frosts, the silvery leaves remain on the bush until new ones are developed. Even without the snowy-white flower-bells this variety is almost worth growing

Flowers of *Zenobia speciosa pulverulenta*.

for the sake of its pretty frosted foliage. *Z. speciosa nitida* is a form with foliage of a bright-green colour on both surfaces. In other respects it is like the form here figured.

5592.—Flowering creepers.—Climbing Roses of any kind would do well. The White Bankian, Climbing Aimee Vibert, Lamarque, or some such old-fashioned kind as these: *Jasminum nudiflorum* would give a glimmer of yellow with its flowers throughout the winter, and you could plant also the smaller flowered Clematises, the *Lahrusca Grape*, which has berries that change to very rich tints in the autumn, or Clematis Jackmani. Its deep purple-blue flowers tell well with a dark background, such as afforded by an old tree-stump. You might also plant against them such a beautiful *Berberis* as *B. microphylla*; the double *Kerria*, which produces its double yellow flowers in spring; *Honeysuckles*, such a *Rubus* as the Cut-leaved Bramble, or *Rubus phoenicolasius*, which has scarlet fruit.—C. T.

— This is an admirable way of using old trees, although few ever think of doing it. In gardens the rule is to put climbers on walls or fences, where some restriction is of necessity bound to be performed. Of course, they are most useful, but then we never see them in all the graceful beauty that belongs to them when abandoned as it were to themselves. I should advise "Ignoramus" to plant *Clematis montana grandiflora* to bloom in spring, and *C. flammula* for autumn, as both are adapted to this free, wild growth, and flower magnificently. For summer blooming a Rose might be included, *Felicite Perpetue* being a very suitable kind. Then there are the *Honeysuckles*, and of these nothing better or more brilliant than the Red Trumpet kind (*L. sempervirens minor*), unless the situation is too cold, in which case one of the commoner kinds must be planted. I once had an *Aristolochia Sipho* growing on a Laburnum-tree, and the effect was splendid, especially when the *Lahurum* was in flower. Its flowers are rather insignificant, and very curious, but the great leaves make a fine show.—A. H.

5593.—Hedge for a wind-guard.—You can plant Flowering Currant (*Ribes sanguinea*) and Flowering Currant (*Ribes aureum*); these are fast growers, and handsome in April and May. If you care for Evergreens you may plant the common Yew or Green Holly. If well planted in March, and watered well during dry weather, will make a good hedge, being pretty fast-growers.—F. O. D.

5475.—Blight on Beech-trees.—I think the cause of the information he needs. The blight which has caused the lovers of our wooding in the County of Ireland much regret for some years is due to a little

Wcevil named *Orchestes laqi*. The larva, a leaf-miner, feeds on the inside green part of the leaf, causing it to wither. I believe there is no practicable remedy.—R. L. A.

NEGLECTED SHRUBS.

THE STUARTIAS.

FORTUNATELY, in some gardens the precious introductions of former times have not been discarded to make way for the reigning fashion, and so we have perpetual object lessons before us to impress on our minds the mistakes and shortcomings of those who neglected to duly care for such truly beautiful shrubs as *Stuartia penta-*

gyna and *S. virginica*. All the *Stuartias* grew slowly, particularly in a young state, and require to be fully established before they develop their full beauty. Propagation is most readily effected by means of layering.

STUARTIA PSEUDO-CAMELLIA was first introduced into, and flowered in, this country by Messrs. J. Veitch and Son, who exhibited fine sprays of it in full blossom a few years ago at one of the meetings of the R. H. S. The foliage of *S. pseudo-Camellia* somewhat resembles that of some of the *Camellias*, and is beautiful at any time, but in some seasons the brilliant crimson and gold autumnal tints render the species most attractive, much more so than its American relatives at that period of the year.

S. VIRGINICA (here figured).—This is described in some books under the name of *Stuartia Malachodendron* and *S. marylandica*. Fine specimens of this exist in the gardens at Syon, Coolharst, &c., where they appear to be quite at home. According to London this species was first introduced into this country in 1742; it flowers from July to September, and is one of the most beautiful of all summer-flowering shrubs. The blossoms are large, and the purple filaments form a striking contrast to the white petals. In a wild state it is found along the coast regions from Virginia to Florida, and affects damp or swampy spots. Under cultivation it does well in peat and loam, or in pure loam and even in deep sandy soil, provided it has a good supply of moisture at the root.

S. PENTANDRA.—This has less hairy leaves than *S. virginica*, and the flowers are creamy-white, the petals having crenelated margins, and produced in profusion during the months of July and August, and are borne singly on very short stalks in the axils of the leaves; they measure 3 inches or 4 inches in diameter, and like those of the last-named species have reddish or purple stamens. G.

5504.—Ivy for a fence.—The Irish Ivy (*Hedera canariensis*) is the best for quick and dense growth, having regard to its hardiness and the position it is to occupy. Common plant that Ivy is considered to be it is not averse to liberal treatment in the way of manure to its roots, or liquid-manure, given during the summer when the weather is dry. If the ground is deep dug and well manured at planting time, it will all the sooner cover the posts and chains. Any nurseryman will supply the

plants; no better time for planting than early in March. Two stout plants to each post ought to be put in.—S. P.

You can do better than choose Emerald Green, or Gem, as it is sometimes called, a very quick-growing, glossy-leaved variety; but you might make your fence more interesting than this. Why not plant against it *Honeysuckles*, the winter and yellow-flowered *Jasminum nudiflorum*, *Clematises*, or the Vines, such as the fine-leaved *Lahrusca Grape*. But of course Ivy is evergreen, and if you put in good plants, and prepare the soil well, you will get quicker growth than if these points were not considered. Ivy is as a rule badly treated in gardens. You can get this variety or any other at any good nursery.—C. T.

The two kinds of Ivy that I should use for such a purpose are the Irish and the heart-leaved varieties. Both are fast growers, bold, handsome, and effective always. Any nurseryman that grows trees and shrubs in quantity for sale would be able to supply these two kinds.—A. H.

5424 and 5536.—Aster Thomsoni and Trachelium corniculatum.—"E. A. M." can get *Aster Thomsoni* from Mr. W. Thompson, Taverners-street, Ipswich. It is in his list. So also is *Trachelium corniculatum*, imported for February 10th, 1894. This does nicely in a pot, but is said to be hardy.—Nemo.

5502.—White growth on soil in pots.—This is usually the result of a disarranged drainage in the pots, and nothing but a thorough examination will be effective; or you have kept the soil too moist. No doubt you gave too much guano, and such manures require very careful use, otherwise more harm than good is inflicted.—F. F.

5556.—Bulbs after flowering.—It is not necessary in every case to lift bulbs after flowering. In a general way it is better to lift choice things, such as Tulips, Hyacinths, Gladioluses, and Ranunculuses when quite ripe, and after drying well, pack them away till it is time to plant them again. By this method the offsets can be separated from the old bulbs and started alone. Other bulbs, such as Narcissus, Crocuses, Snowdrops, &c., which are frequently left altogether in the ground, should be lifted occasionally for the purpose of thinning them. Once in three years will be often enough for most practical purposes.—E. H.

Bulbs are much better left in the ground where they grow if they are not in the way of summer-flowering subjects. In that case lift

Flowering-shoot of *Stuartia virginica*.

them carefully up when the foliage decays, lay them in an airy dry shed to thoroughly ripen off for a week or two, then store them in a dry room in paper bags until planting time comes round again. Should it be necessary to dig them up before the foliage has turned yellow, lay them in some soil until the foliage does turn yellow, so that the ripening may be gradual.—S. P.

CHRYSANTHEMUMS.

5553.—*Chrysanthemums for show.*—It is too late now to strike cuttings with a fair prospect of winning prizes next autumn. The best plan would be to purchase plants from one of the many dealers who make Chrysanthemums a speciality. When received, pot them at once in 3½-inch pots in a compost of loam two-parts, one-part half-decayed horse-manure, a good sprinkling of sharp silver-sand, with a handful of dissolved or ground bones thrown into every peck of the compost. Do not top the plants, but allow them to grow on with one stem until the first natural break is made in April or May, according to circumstances—such as the time the cuttings were inserted, and the variety. The formation of a flower-bud in the joint of the shoot is the cause of the first break taking place. Remove the bud and select three of the most promising shoots; these are generally at the point and nearest to where the bud formed. When potted place the plants in a cool-house as near to the glass as possible, so that they will grow sturdily by receiving all available light and air. When new growth is fairly on the way, and the pots are nearly full of roots, stand them in a cold frame placed in a sunny position. Here growth will be more stocky. Remove the lights entirely during fine weather, but be careful in admitting air when the weather is unfavourable. Transfer the plants to larger pots as those in which the plants are growing fill with roots until they are in 9-inch pots, which are the best size for flowering them in. Keep the plants quite free from insect pests and mildew, such as green and black-fly. These are easily got rid of by dusting the parts affected with Tobacco-powder, syringing it off the next day. Sulphur is the best cure for mildew, sprinkled on the affected parts, keeping the air about the plants at the same time sweet and clean. The following is a good selection of varieties, all of easy growth—Japanese: Avalanche (pure-white), Col. W. B. Smith (old gold-yellow, tinged with terra-cotta), Edwin Molyneux (crimson and gold), Etoile de Lyon (deep lilac-rose, shaded silver), Excelsior (rose-cerise, silvery reverse), Florence Davis (white, with tinge of green in centre), G. C. Schwabe (carmine-rose, gold centre), Lord Brooko (bright bronze-yellow), Mlle. Marie Haste (creamy-white, faintly tinted blush), Sunflower (deep yellow), W. H. Lincoln (bright yellow), Vivian Morel (dusky-maroon), W. Luckner (sweet delicate-rose), William Seward (deep, rich, blackish-crimson), Mrs. C. H. Payne (rosy-lilac), Charles Davis (rosy-bronze), Golden Wedding (richest golden-yellow), and Mlle. Therese Rey (creamy-white). Incurved: Empress of India (pure-white), Golden Empress (golden-yellow), Lord Alcester (primrose-yellow), Queen of England (deep-blush), Mrs. S. Coleman (golden-bronze), Princess of Wales (blush, tinted rose), Mrs. Norman Davis (yellow), Princess Teck (blush-white), Prince Alfred (rosy-carmine), Mme. Damer (mauve-yellow), M. R. Bahmut (carmine-rose, shade cerise), Jeanne d'Arc (white, tinted rosy-purple), and Lord Wolseley (bronze-red). Reflexed: King of Crimson (rich bright-crimson), Christine (golden), Christine (pink), Christine (peach), Mrs. Farayth (white), Cloth of Gold (pale-yellow), Cullingforth (scarlet-crimson), and D. Sharpe (magenta). Anemone: Mrs. Judge Benedict (light-blush, changing to pure-white), Lady Margaret (pure-white), Gluck (rich yellow), Jeanne Marty (rosy-peach), Fahim de Mediana (deep-lilac), and Duchess of Westminster (silvery-blush).—E. MOLYNEUX.

5563.—*Ostrowskia magnifica.*—This is quite hardy and to grow it properly it must be planted out-of-doors. The thick, fleshy roots when full grown are nearly 2 feet in length, and therefore to have any measure of success with the plant a deeply-worked soil is very essential. As regards the kind of soil, it is not very particular, but prefers a deep, sandy loam. I should advise "K. K." to choose a favourable spot, thoroughly prepare the soil by digging it to the depth of 2 feet, adding well-decayed manure, and then put the roots in. The roots are exceedingly brittle, and great care is necessary in handling them when they grow large. The young shoots start into growth early in the year, but they do not suffer from the spring frosts.—A. H.

FERNS.

SHIELD FERNS (POLYSTICHUMS).

This is a large genus, comprising somewhere about half a hundred species, which have a wide geographical range. A few only of the greenhouse kinds are included with the *P. venustum* from New Zealand (here figured). Polystichums have an especial advantage over the Buckler Ferns (*Lastreas*), inasmuch as they are ever-

Frond of a Shield Fern (*P. venustum*).

green, and their beautiful fronds remain perfect through the winter months, whilst the majority of the *Lastreas* are deciduous. The genera *Polystichum* and *Lastrea* resemble each other very much, and some instances occur in which it is hard to decide to which of the two families a plant really does belong, but, as a general rule, in *Polystichum* the indusium is shield-like, that is, circular and peltate, whilst in *Lastrea* it is reniform. The habit of *Polystichum* is more rigid, the fronds being usually shining and

spiny at the points of the segments, this rendering them extremely useful for cutting. The following are distinct and handsome kinds, and they will all thrive under greenhouse treatment. All are easily grown if potted in a mixture of about two-parts good light turfy-loam and fibry peat in about the proportion of two-parts loam to one of peat, the whole well mixed and made fairly sandy. The pots should be well drained, for the plants like a liberal supply of water at all seasons, but especially in the summer when they are growing.

P. VENUSTUM.—The frond here figured was sent to me by Mr. Angel from New Zealand; when fully grown the fronds are each about a foot or 18 inches long, bipinnate, deeply lobed, with spiny margins, deep-green on the surface, paler below. Its chief distinguishing feature lies in the presence of a dense band of imbricating scales, which are black, bordered with brown, and which extend the whole length of the frond.

P. VESTITUM is another species from New Zealand. Specimens of this plant I have received through Mr. Eric Craig. It is a fine plant for the cool fernery, having almost lanceolate fronds some 18 inches long, the colour rich deep-green.

P. CAPENSE.—This is a very much larger plant than either of the two previously named. It makes a stout creeping rhizome, from which grow fronds some 3 feet and upwards in length. It has an arching and graceful habit. It thrives well in the cool-house.

P. FRONDOSUM.—A native of the island of Madeira, making fronds from 1 foot to 3 feet in length; these are finely divided and rich bright-green in colour. These fronds are admirably adapted for cutting for mixing with flowers in large vases.

P. PALMIFOLIUM, from the same country, is quite a different plant. It is a very handsome and distinct kind with fronds some 18 inches or 2 feet long. The pinnae are large, bright-green on the upper side, whitish-green below, where the sori are large and conspicuous, rendering it very attractive.

P. FORIFOLIUM comes from various places in the East, but I have grown the Ceylon plant into grand examples in the cool fernery and used its fronds with much satisfaction for cutting. The fronds, from 1 foot to nearly 3 feet long and 1 foot in breadth at the base, are deltoid in outline, finely-divided, spiny-edged, and rich bright-green in colour. W. G.

5566.—*Maiden-hair Ferns, &c.*—These are not very satisfactory in a room, and much hardier and more robust things are desirable, such as the *Pteris tremula*, *P. cratica*, &c. You may grow in the window-box many things. The Bell-flowers (*Campanulas*) are a host in themselves, and the pretty *C. muralis* and *C. carpatia* will produce a wealth of bloom, and they grow almost like weeds. Then you could have a few Zonal Pelargoniums, *Fuchsias*, Ferns—such as those mentioned recently in *GARDENING*, Feb. 3, page 681—and bulbs, such as Hyacinths and Tulips, for the spring. But, of course, you cannot expect great things from an inside window-box, and the plants recommended for those outside (and several notes have appeared lately on them) will do.—C. T.

(5416) I will give you a few hints about potting and compost for Ferns. One great point is to drain the pots well, otherwise the soil will get waterlogged, and the fronds quickly die off. This is of greater consideration even than the soil. If you are growing Maiden-hairs you may have a soil either of peat or loam, either sufficing, but for Ferns in general I may say that the soil should be composed of loam and good fibry peat in equal parts, to which should be added a part of well-decayed leaf-mould, and a dash of sharp silver sand. A little charcoal may be mixed with the compost, if thought advisable, to keep it porous. After potting, water sparingly, and until the plants have got well-established—a too moist soil prevents the roots of the Ferns working into it freely.—C. T.

Better buy a few small plants of the Maiden-hair Ferns for the cool greenhouse. Belgineellas of the hardier sorts can easily be raised from cuttings in sandy soil, kept moist in a shady spot, any time during the spring or summer.—E. H.

Drawings for "Gardening."—Readers will kindly remember that we are glad to get specimens of beautiful or rare flowers and good fruits and vegetables for drawing. The drawings so made will be engraved in the next number of *GARDENING ILLUSTRATED*.

FRUIT.

CULTURE OF FILBERTS.

In reply to "G. F.," and others, the following is the practice in some parts of Kent: The trees when young are cut back to within 1 foot of the ground, which causes them to emit side shoots, which are regularly trained outwards by being tied to a wire or wooden hoop, which is placed in the centre, so as to give the tree a cup-like form. This is a capital method, inasmuch as it

Filbert "Mount Atlas"

allows the sun to shine in the centre as well as all round the trees, and thus the wood gets well ripened, a condition indispensable to the production of large crops of Nuts. Nut-trees are, as a rule, to be found alternately planted with standard Apple or Pear-trees. In height they are seldom allowed to exceed 6 feet, severe pruning being yearly resorted to in order to keep them within bounds. Many of the established bushes are 15 feet in diameter at the top, and are as flat as a table, and a crop of Nuts is generally to be depended upon. Good kinds of Nuts and Filberts are as follows: Cosford (early), Lambert Filbert, Mount Atlas (here figured), a fine productive kind, Pearson's Prolific, Round Cob, and White Filbert.

H.

6595.—Planting Apple-trees, &c.—If only the bare, fibrous roots were cut off no harm was done; but it would not have been wise to cut off all fibrous roots as well. It is the large roots that are devoid of fibre that are the cause of fruit-trees requiring a check by root pruning, which induces them to make fibre. In the case of soil that is light and warm it should be trodden down firmly, providing it was done when in a dry state. It would be folly to slope the soil down to the trunk, as suggested for the idea of making a basin-like cavity around the stem. Fruit-tree roots should be as near to the surface as possible without being exposed to the air, and to make a mound around the stem would be to drive the roots further still from the surface. If the trees have shoots 2 feet long say, cut them back to within one foot of the base. This is a fair distance to prune all the shoots back to. Now that the trees are newly planted it would be wise to mulch the surface of each for 2 feet around, and away from the stem, with half-rotted stable-manure, if available. If manure cannot be obtained a 3-inch thickness of decayed vegetable-refuse and wood-ashes would prove beneficial. Mulchings like these not only preserve the roots from frost, but maintain the soil in a moist state during the summer.—S. P.

5575.—Treatment of Pear-trees.—Thoroughly syringe the trees now with a strong solution of soapy water, to which is added 1 wine-glassful of petroleum to every 3 gallons of liquid. If this does not remove the insects well

brush into the worst parts methylated spirits. If liquid-manure is available, well soak the soil for at least six feet away from the stems of the trees. If the trees are above ten years old, extend the liquid another couple of feet. If this stimulant is not to be had, remove the Grass for at least 6 feet away from the stems, and work some partly-decayed manure into the soil a few inches deep, replacing the Grass. If the trees are not very large, it is not wise to allow the Grass to grow close up to the stems; much better have 4 feet all round the stems here, so that the sun will warm the soil, and encourage the roots near the surface. This is most important, especially if the soil is at all inclined to be heavy in character. Guano is a good stimulant for any kind of fruit-trees. The best way of using it is by sprinkling it on the surface when the fruit is the size of Walnuts, and washing it in by well soaking the soil with clear water.—S. P.

5591.—Growing Melons in a vinery.—As you have been so successful with Cucumbers in the vinery, there is no reason why you should not manage Melons also. If the plants are raised in the Cucumber-house, which will be a suitable place, and they are 6 inches high when the bunches are visible on the Vines, then would be a suitable time to plant the Melons. Do not allow them to carry too many shoots, keep them rather thin, and fertilise the female blossoms when they are fully expanded with pollen from the male blossoms. Hero of Lockinge would be the most suitable green-flesh variety, Blenheim Orange the best scarlet. Keep the foliage well syringed, except when the plants are in bloom. In giving water do not wet the stem at the surface of the soil any more than can be helped, as it tends to canker.—S. P.

PYRAMID PEAR-TREES.

The appearance of lines or groups of healthy pyramid Pear-trees is a highly ornamental, as well as useful, feature in any garden. A suitable location for planting them is in a single line on either side of a garden walk. In such a position they are easily got at for the purposes of pruning, protecting the blossoms in spring, and gathering the fruit when ripe. A perfect specimen of a pyramid Pear-tree ought to be quite symmetrical, and the growth of each branch springing at regular intervals from the main stem should be straight and clean, and the whole tree should be furnished from base to summit with branches well set with fruit-spurs, and which should never be allowed to become overcrowded. The breadth of a good specimen tree should be equal to about one-third of its height. Pear-trees of pyramid shape, ready trained, can generally be purchased in most good fruit-tree nurseries, but, of course, they are much more expensive than maiden trees. If these latter are procured the grower can train his own trees, and often a better result is obtained than when stock is purchased that has been a long time in the nurseryman's fruit-quarters, and, consequently, frequently has become crippled and stunted in growth, and rarely producing satisfactory after-results. Commencing then, with the maiden tree, one year worked before replanting, it is better to let it grow for the first season

WITHOUT PRUNING at all; this operation is one requiring much care, so as to ensure the base of the tree operated on being well furnished with strong and fruitful branches, which must be fully borne in mind when cutting back. The summer following the first pruning the young trees will generally push out a considerable number of vigorous shoots, and these, when a few inches long, should be thinned out, and

remove entirely every shoot from the base of the stem to a height of about 1 foot. Thin out those above that point to, say, six, seven, or eight shoots, taking care to preserve the best placed shoots, and they should be arranged, as far as possible, at regular intervals. If in the course of the summer season they evince a disposition to unevenness of growth, then regulating the same by pinching with the thumb and finger must be resorted to, of course preserving the leading shoot intact. In the autumn pruning of this season the lateral branches of the preceding summer's growth should be cut in much shorter than the lower ones, to favour the development of the same. This routine of pruning and training may be said to apply generally to their culture throughout their career, taking care, however, as the trees increase in size that the terminal growths of the lowermost branches be not allowed to extend too wide. This can easily be avoided by timely pinching in the summer season. The best season for planting Pears, in common with all other fruit-trees grown in the open air in this country, is in the early autumn, and the soil in which they generally thrive best is in a good, rather heavy, well-drained, loamy one; but by careful attention to manuring the roots, giving plenty of water where possible, and mulching them in hot, dry weather, they can be grown extremely well in almost any soil. During the flowering season protection of the blossoms from frost is very desirable, and the form of the tree renders the application of this by no means difficult. A light wire or wooden framework can be placed around the trees, and a light canvas covering, made to put on or take off easily, is about the best thing to employ for the purpose. In a general way this protecting medium should be removed in the daytime; but when in the spring a black, frosty north-east wind is blowing, it may often be left on during the day with great benefit; but this remark only applies to very bad weather.

A GOOD SELECTION of Pears suitable to form pyramids for almost any garden would be the following—viz., Marie Louise, Beurré Hardy, Jargonello, Beurré d'Amant, Citron des Carmes, Colmar d'Été, Glen Morecan, and Gilgill. The illustration annexed shows a specimen of another form of this kind of training, called the winged pyramid. The chief advantages of the latter plan are the preservation of

Winged Pyramid Pear-tree in bearing.

the fruit from destruction by wind, and in the exposure of both fruit and wood to the sun.—B. Original from 5571. Young fruit-trees.—I presume that a young tree trained horizontally, in

that case cut the main stem back sufficiently far to ensure another pair of side branches and a leader. The side branches should come from the main stem at the same distance as those below. In the case of Peas the branches are usually trained at every other line of bricks. Select the bud opposite the line where the branches are required to give the leading shoot for next season's growth. In the case of fan-trained trees that have made vigorous growth, say 2 feet shoots, cut these back to within 15 inches of their base. This will ensure the eyes near the base starting into growth and thus furnish the tree evenly all over with branches, to grow eventually into fruiting shoots. Always cut the shoots to the most promising bud at the upper side of the shoot, as from this position the new growth is more uniform and has the best appearance in the future. Any side branches not required should be cut to within an eye or two of the base; these will in time form fruiting spurs. In the case of Plum, Cherry, or Peach-trees, a space of 4 inches is a good one to allow for the side shoots. — S. P.

— Cut the central stem back to 1 foot from the last pair of branches. The leaders of the side shoots should not be shortened till all the space has been filled up, but the breast-wood should be spurred back to three buds. — E. H.

5530. — **Peach-growing.** — Seeing that you are about to build a house specially for Peaches and Nectarines, I advise you to do the work well by having all the parts of a substantial character. The back wall should be 8 feet high, and the back lights not less than 4 feet in length. You do not give the length of the proposed house, as to a certain extent the width should be guided by the length, or the external appearance will not be pleasing. Fourteen feet is a very good width. This gives a barrier 8 feet wide for the trees in front, which I suppose you intend to train on wires under the glass, a walk 3 feet wide, and a border the same width for the trees that will be trained on the back wall. Three Peaches that will ripen in succession are Alexander, Early Grosse Mignonne, and Sea Eagle. If you want a fourth select Stirling Castle. The best Nectarines are Elruge, Lord Napier, and Victoria, and Pine-apple for a fourth. — I. C. C.

— The following six Peaches will give a good succession of fruit, all of excellent quality: Royal George, Bellegarde, Barrington, Violet de Hutive, San Eugh, and Wallburton's Admirable. Four good Nectarines are: Elruge, Lord Napier, Pine-apple, and Pittaston Orange. All of these are free-bearing kinds, and really good in quality. The height of the back wall should be 10 feet, the width of the house 16 feet. By having a curved trellis in the front of the house the back wall can be better utilised. — S. P.

— Make the house as high and as wide as you can. Small houses are not well adapted for Peach growing; and plant about two or three kinds. There is no better seller or proper than Royal George. Diamond is also an excellent Peach. I should include Lord Napier or Humboldt Nectarine. — E. H.

5531. — **Stable-manure.** — The price of stable-manure may vary in different localities and different seasons of the year, especially in towns, where manure must be cleared away. I have a contract to take all the manure from a railway stable at 3s. per ton. I find it more satisfactory to buy by weight, and this I should say would be a reasonable price anywhere. A ton of stable-manure would be about a load and a half for an ordinary cart. The country district farmers frequently supply the straw, and take the manure as an equivalent; but of late years straw has been worth more money. It is a matter of bargain, and a good deal depends upon the demand for manure. — E. H.

5532. — **Hyacinth bulbs.** — The only way is to store them in sharp silver sand or Coconut-fibre refuse after they have got thoroughly ripened and dried. I presume the bulbs are in pots, and a good way to deal with them is to plant out in the autumn after they have been stored during the summer, as such bulbs make very pretty effects when planted about on the rockery or roostery, as one does not look so much at the beauty of the individual spike as at the colour gained. If you mean you have a lot of bulbs left out of the ground or pots, and you wish to keep for another year, I am afraid they will do little good, the best part being dead. Plant or pot them at once if you wish to keep them. — C. T.

THE KITCHEN GARDEN.

SCARLET RUNNERS.

Few vegetables are more productive than a well-managed row of Scarlet Runners. By keeping all pods picked off as soon as large enough, one small row will produce enough for the consumption of an ordinary family. For the supply of a large establishment I make two sowings, the first at the latter end of April. This I generally make in a sheltered corner on hard ground on which is spread about 3 inches of fine soil, and then I scatter the seeds evenly over it, covering

OUR READERS' ILLUSTRATIONS: Scarlet Runner Bean "Painted Lady." ENGRAVED FOR GARDENING ILLUSTRATED FROM A PHOTOGRAPH SENT BY MR. NORMAN BLAKE, BELFORD.

with the same kind of material, and if kept moist they will be fine plants by the middle of May for transplanting. A few branches are laid over them on cold nights. I generally plant in trenches prepared as for Celery, except that they are filled up level after the manure is dug in. The plants are carefully lifted and replanted with a trowel, and straight rods about 9 feet high are driven in on each side of the row, and fastened to one placed horizontally about 6 feet from the ground. These form an immovable framework for the haams to run on. As soon as planted I put a few evergreen branches outside the stakes for shelter, and place a mulching of partially decomposed manure 1 yard wide on each side of the row; a good soaking of water or liquid-manure is also given about every alternate week, and thus treated they keep up bearing for a long time. I sow a few rows the first week in June for a very late crop, and in seasons when the frost keeps off they are very prolific during October, and sometimes in November; any way one takes them they are an unfailing crop, and generally preferred beyond Dwarf or Broad Beans. The sorts which I grow are the old Scarlet (Painted Lady) (here figured), and Champion and Girford Giant Runners. J.

Mushrooms for market. — Mushrooms will pay for growing for market if

the work is undertaken by those who understand what they are about; but I should say they are very unlikely things to pay under the care of those who know nothing about the practical part of their management. There is no simple way of starting in this business, as all the details must be carried out with skill and care or failure is sure to follow. — J. C. C.

5576. — **Kitchen garden paths.** — There is nothing that has such a good appearance as gravel for garden paths when kept in good order, but there is no gravel that is weed-proof. This, however, is easily managed by the aid of weed killers, which are now cheap, and save a lot of labour. They not only kill the weeds, but brighten and clean the gravel, making it look like new. The autumn, say October, is a good month to apply them. Tar and gravel make dirty-looking paths. I am sure you would not like them. The tar is very objectionable during hot weather, not only in its smell, but is soft to walk upon. Much depends upon how the foundation of the paths are made whether they will grow many or few weeds. If the gravel is simply laid upon the soil, as is a too common practice, no wonder then that weeds come up thickly. To render garden paths dry, and to preserve the gravel a long time, also a 3-inch thickness of broken stones, bricks, or clinkers should be laid under the gravel. The bottom of the path and the stones should be in exactly the same manner as the finished gravel surface is to be. If a path is 5 feet wide, the centre should be 3 inches higher than the sides, to allow for water from heavy rains to quickly pass away. Before laying on the gravel well roll the stones in shape. Not nearly so much gravel is used then in filling in the interstices, and it is easier also to make an even and smooth surface. Choose a dry day for laying the gravel. For ordinary garden paths it should not be less than 2 inches thick when laid on loosely, to be compressed into about 1 inch by rolling to make a firm and lasting path. It is best to apply the desired thickness, at once raking the surface level. After drawing a roller over the gravel to press it down, make it thoroughly wet by pouring water on the moving roller through the rose of a waterpot till a smooth surface is obtained. The rolling ought to be continued until the gravel will absorb no more water, but stands on the surface, then cease. The path must not be walked upon for a few days to allow the gravel time to "set." Then use the roller again till the surface is quite smooth and firm. Gravel paths cannot have too much rolling, provided it is done judiciously. — S. P.

5543. — **Seakale roots.** — Leave the roots in the ground, and thin out the crowns to one, or at most two. — E. H.

— Yes; Seakale roots are valuable after being forced, but they must be kept free from frost, and the roots kept in soil after they are taken out of the forcing-house. Towards the end of April plant them out in good ground in rows 2 feet apart, and 15 inches between the sets. If a number of growths appear on each crown in the summer reduce them to one, as one crown to a root is better than two or three. The plants will not do for forcing next year, but the year after they will be as strong as at first. — J. C. C.

5573. — **Fertilising blooms of Tomatoes.** — Do not worry yourself about fertilising the blooms of Tomatoes, because any attempt to do so does neither good nor harm, for the reason that it is a difficult matter to reach the organs of the flower that would be affected by it, and those who tell you that it benefits the crops in any way would find it difficult to prove the truth of their assertion. Thinning out the fruit is a far more reasonable operation to recommend, especially towards the close of the summer, when the plants are getting exhausted. Even then I do not know that the weight is increased; the fruit is, however, larger. The first blossom in every bunch of flowers should be pinched out, as the fruit invariably comes deformed. — J. C. C.

5542. — **Crops after Celery.** — Root crops, such as Carrots, Parsnips, Beet, and Salsify follow Celery very well; the extra digging and moving of the soil required in earthing the latter is in favour of those crops named. Onions also follow Celery well—in fact, any kind of vegetable will succeed after Celery.

Cabbages or any of the Brassica tribe rob the soil the most of any vegetable. After a piece of ground has been cropped by any of these a heavy dressing of manure is essential to replace those ingredients absorbed by these crops.—S. P.

Root-crops, such as Carrots, Beet, or Turnips, come in well after Celery, as would also Cauliflowers, Beans, and Peas—in fact, Celery forms a good preparation for any crop. But in digging it over the old manure from the trenches should be distributed through the land. This can best be done by digging across the trenches.—E. H.

5585.—**Growing Tomatoes.**—The only doubt in your case is the ventilation. If you can open the sidelights as well as give air at the top you will be right enough. Make a bench over the pipes on each side to hold the soil, keeping the bottom of the bed 9 inches away from the pipes. The heat from the latter will not then interfere with the roots of the Tomatoes, as I hope you will not want to use fire-heat after the end of May. You will find a bowl of soil far preferable to growing the Tomatoes in pots. J. C. C.

5508.—**Soil for Tomatoes.**—It is not necessary to change the soil every year. Trench the border in the usual manner, adding a fair quantity of good rotten manure, then dress with kainit and water well in. When sufficiently dry fork it over, and prior to planting give also a dressing of some good artificial manure. The addition of a mixture of lime and soil is also beneficial.—P. F. L. S.

I have grown Tomatoes in pretty near this same soil in one house for five years,

5568.—**Tomatoes from seed.**—If the frame is quite cold it will be better to sow the Tomato-seeds in the window of a warm room in March. Prick them off into small pots or boxes when large enough, and then move to the frame, and keep close for a time, and securely covered up at night. Harden off and plant out at the end of May.—E. H.

It is useless to sow seed of Tomatoes in a cold frame until quite the end of April, and then you will not get any ripe fruit until August. It would be far better to purchase a few plants at the end of May. Tomatoes require a long season of growth, and it is to do any good in our short summer must be sown early in the year in heat.—B. C. R.

5590.—**Cauliflowers dying off.**—This sometimes happens when the seeds have been sown too thickly in heat. As soon as the seedlings are up move to a house where more air can be given, and prick off as soon as they can be handled.—E. H.

5194.—**Grubs on vegetables.**—You should give the ground a good rough digging or trenching during winter. At present I would advise you to give all the grounds intended for cropping this year a good dressing of hot lime and soil, and manure this year with rotten seaweed, and you will find the grubs less in number.—P. O. D.

BERMUDA LILY (LILIUM LONGIFLORUM HARRISI).

This beautiful Lily is evidently growing in popularity, and that rightly so. Being so amenable to pot culture for flowering at almost any season of the year, it is greatly appreciated, more particularly in the trade and by the florists and decorators. In many private gardens it is also grown, but its culture in this direction does not appear to be taken up so extensively as one would imagine, especially where large conservatories have to be kept gay, or where a quantity of choice cut flowers has to be provided. Last

from that time up to May and June from the Bermuda importations. Those following in June, July, and August I have a shrewd suspicion are Cape-grown bulbs. I have myself purchased them as such in the spring. Those blooming the earliest will give a few more flowers from succeeding growths the following autumn; thus the year is nearly or quite bridged over where necessary. Light loam and leaf-soil, with plenty of sand or road-scrappings, will suit this Lily well. Green-fly is a troublesome pest, but can be kept down by the usual methods. This Lily revels in a humid atmosphere when being forced, and takes water freely when well rooted. How it came to be designated *Harrisi* I do not know; I fail to see any difference between it and the type other than what may be expected in the case of vigorous bulbs grown under more congenial conditions in a warmer climate. This I consider makes all the difference, for I have noticed that *Harrisi* (so-called) reverts to the normal type after a season or two in this country. A good proof in support of this is the fact that *L. longiflorum* has been sought for in quantity in this country and on the Continent for sending out to the Bermudas, where after a season or two's growth they would return in the improved form to this country. The conditions under which the bulbs are grown is, in my opinion, the only cause of variation as seen between home-grown and imported ones. As to their culture at the Cape, it is only reasonable, being a means of further extending the season. This is done, we know, in the case of the *Tulhe-*

OUR READERS' ILLUSTRATIONS: Bermuda Lily (*Lilium longiflorum Harrisi*). Engraved for GARDENING ILLUSTRATED from a photograph sent by Messrs. Hobble and Co., Rothsay, N.B.

and I do not see any difference in the behaviour of the plants now than during the first season. I, however, do freshen up the soil every year before planting by removing a little of the old surface and giving a dressing of fresh earth or rotten manure, as I do not believe in starving Tomatoes. I have seen the plants as badly diseased in a new house and perfectly fresh soil as ever I saw in older structures. At the same time I must say that nearly every other crop I grow is benefited by a change of soil.—J. C. C.

5557.—**Unsatisfactory Tomatoes.**—Tomatoes may be grown in a gravelly soil, but it must be understood they require more support than in the ground is heavier. The soil should also be made firm before planting. The cause of not setting is very likely to be soil lacking in moisture and perhaps they are not sufficiently ventilated.—E. H.

season I saw a house full of this variety in the best possible condition and in various stages of growth. The plants in bloom were some 4 feet in height, with from four to six well-developed flowers upon stout stems. The house in which these were being grown was kept at a stove temperature, warmth being evidently congenial to them. For the earliest flowering the bulbs should be secured as soon as they arrive from the Bermudas. This will be at about the same time as the Roman Hyacinths arrive from the south of France.

Forcing must not be attempted until some new roots have been made; then even the temperature should be worked up gradually for a time by taking all possible advantage, the earliest may be had in flower during December or even in November. Successions are easily obtained

rose, why not also in that of the Lily in question? A word upon the custom of the florists in depriving the flowers of their pollen-vessels is necessary, the flowers being thus shorn of a part of their beauty. Why not dip or touch these parts with gum-water instead, so as to prevent the pollen from tarnishing the flowers? Or wrap a little tissue paper around the vessels until the blooms are in actual use? Anything is better than thus robbing the flowers of a part of their attractiveness whenever and wherever it is possible. The plant that produced the flowers here figured was potted in October, in good turfy soil and sand, a 7-inch pot being used. After being plunged in Cocoa-nut-fibre-refuse in a cold frame till well rooted, it was removed to a cold greenhouse, and flowered in July. S.

URBANA-CHAMPAIGN

OUTDOOR PLANTS.

CHOICE ALPINE PLANTS.

SILVERY HAIRBELL (EDRAIANTHUS PUMILIO).

This (here figured) is a brilliant little alpine with flowers that look large in proportion to the plant. The little close-set tufts of glaucous foliage look sharp and thorny like a Prick

Silvery Hairbell (*Edraianthus Pumilio*). Engraved from a photograph.

Thrift, but prove of a milder nature on closer acquaintance. The flowers are of a full rich purple. G.

5563.—**Hardy perennials.**—The following are all useful showy perennials: *Adonis vernalis*, March and April, 1 foot; *Alstromeria aurantiaca*, July and August, 2 feet; *Alyssum saxatile compactum*, March and April, 6 inches to 12 inches; *Achillea italica*, June and July, 3 feet; *Anemone fulgens*, March and April, 1 foot; *A. japonica* (white and red), August to November, 2½ feet; *Anthemis tinctoria*, June and July, 1½ feet; *Auricularia liliastram*, May and June, 2 feet; *Aquilegia chrysantha* and others, May to July, 2 feet; *Arabis alpina*, March and April, 6 inches; *Asters* (*Michaëlas* Daisies) in variety, from September to November, from 2 feet to 5 feet; *Aubrietia Hender-sonii*, March and April, 6 inches; *Bocconia cordata*, June and July, 6 feet; *Bupththalmum salicifolium*, May to July, 1½ feet; *Campanula* (*Bellflower*) in variety, May to July and August where a selection is grown, and they vary in height from 6 inches to 3 feet; *Catananche bieneri*, July and August, 2 feet; *Centaurea montana* (*Mountain Cornflower*) (blue, white, red, and sulphur), May to October, 1½ feet; *Chrysanthemum maximum* (*Ox-eye Daisy*), June to August, 2 feet; *Cheiranthus Marshalli* (*Alpine Wallflower*), April, 6 inches; *Coreopsis lanceolata*, June to August, 2 feet; *Delphiniums* in variety, June and July, 2 feet to 5 feet; *Dic-lannus Praxinolla* (*Burning Bush*), June to August, 3 feet; *Dielytra spectabilis*, May to June, 1½ feet; *Doronicum plantaginum*, April to July, 2 feet; *Eryngium amethystinum*, July to August, 2½ feet; *Funkia sancrociata graniflora*, August and September, 1½ feet; *Gaillardia grandiflora*, June to September, 1½ feet; the hybrid forms of this are very useful, and are easily raised from seeds; *Galega officinalis alba*, May to July, 4 feet; *Geranium* in variety, May to July; *Gium coccineum grandiflorum*, May to August, 2 feet; *Gypsophila paniculata*, July to September, 2 feet; *Helenium pumilum*, July to September, 1½ feet; *Harpagium rigidum*, July and August, 3 feet; *Iberis corifolia*, May and June, 9 inches; *Lathyrus latifolius albus*, June to August, 4 feet; *Lilium* in variety; *Lapinus polyphyllus*, June to August, 4 feet; *Lychnis chalcedonica fl. pl.*, July to September, 3 feet; *Montbretia croceiflora*, July to September, 2½ feet; *Ponies* in variety, June and July, 1½ feet; *Poppies* in variety, 1 foot to 3 feet; *Herbaceous Plox*, July to September, 3 feet to 4 feet; *Potentilla* in variety, June to August, 1½ feet; *Primulas* in variety, flowers in spring, 6 inches; *Pyrethrum* in variety, June and July, 2 feet; *Rudbeckia Newmanni*, July to

October, 2 feet; *Saxifraga* in variety, mostly in spring; *Scabiosa caucasica*, July to September, 1½ feet; *Spiraea aruncus and venustus*, June and July, 3 feet to 4 feet; *Tritoma nobilis*, July to August, 5 feet; *Carnations* in variety; *Pinks Her Majesty* and *fimbriata major*.—E. H.

—Your query requires a longer answer than space can be afforded for at this season. The following bloom during the spring and early summer: *Adonis vernalis*, spring (yellow flowers), height about 1 foot; *Anemones* of sorts, fulgens (crimson), ½ foot; *Arabis alba*, very good to form a broad edging, of white flowers; *Aubrietia*, dwarf; *Corydalis nobilis*, about 1 foot; *Dielytra spectabilis*, about 2 feet (flowers rose), likes a light soil; *Doronicum caucasicum* (yellow), about 1 foot; *Fritillaria imperialis* in variety, or the Crown Imperial, 2 feet; *Ranunculus acemifolius* (*Fair Maids of France*), varying from 1 foot to 2½ feet or more in height (flowers white), early summer; *R. amplexicaulis*, spring (white, yellow centre); *Saxifragas* as edgings. The following bloom in late summer and autumn: *Achillea Ptarmica fl. pl.* (double white), summer, about 1 foot; *Aconito*, 3 feet; *Alstromeria urea*, light soil, 2 feet to 4 foot (orange-red lowers); *Hollyhocks*; *Anemone japonica*, very beautiful, especially the white one, 3 feet; *Michaëlas Daisies* in variety, varying from 1 foot to 5 feet or 7 feet high; *Chrysanthemum Mue. Desgrange*, 2 feet (almost white), September; *Delphiniums*, late summer; also *Ploxes* and *Lilies*, commencing with the white *L. candidum*, and closing with the beautiful forms of *L. speciosum* (*L. lancifolium*), or the showy *Tiger Lily* (*L. tigrinum splendens*).—C. T.

5589.—**Raising perennials.**—All those named by "Perseverance," except *Gentiana*, can be raised out-of-doors as well or better than in the site suggested. If a border having a southern exposure could be set apart for this purpose so much the better. Dig the ground over at once, giving it an opportunity to dry, add no manure, as seedling plants need none. If the weather is favourable, the first week in April rake over the land, removing any stones, and mark out beds 3 feet wide, with an alley between each 1 foot wide. If the soil is heavy scatter a little prepared soil over the beds to receive the seed. Decayed vegetable refuse, wood-ashes, or disused potting-soil, thoroughly mixed together, answers very well. Sow the seed thinly, covering it a ½ inch thick with the compost. Should the weather be hot and dry at the time of sowing the seed, and afterwards, instead of watering the beds, cover them with mats or green boughs. When the plants are large enough to handle prick them out into rows 8 inches wide and 6 inches apart in the rows, or plant them finally where they are to bloom.—S. P.

—The plants named for the most part require to be sown in a shallow pan and placed in a cold frame. It is difficult to advise about the position named. If the seedlings come up, the great point is to prevent them from getting drawn up, as presumably they could be some distance from the light.—S. P.

5581.—**Bishop's Weed.**—I do not know the weed under the name in which you give it. I think, however, you allude to the Ground Ivy or Bastard Balm, both of which are troublesome perennial weeds. Your only chance of getting rid of them is to take up the turf and clear it with a slow fire; then lightly fork over the surface, and about the beginning of April sow the space with Grass-seeds, and lightly cover it with the ashes from the fire. There is no better way of getting rid of the weeds, but you must take the turf off deep enough to get all their roots. Whatever you may put on to kill the weeds will also kill the Grass.—J. C. C.

5581.—**Planting Irises, &c.**—It is getting late now to plant the bulbous Irises, as the bulbs ought now to be making roots, but the German Irises may be planted now, and if the plants are strong they will flower this season, though not so well as if they had been previously established. The English Irises are among the hardest of the race, and they are very easy to cultivate.—E. H.

—It is late now to plant, and the first year the results will not be satisfactory perhaps, as Irises require time to get them to bloom in perfection. You may plant the German Irises now, and this will thrive in ordinary soil if mixed with a little well-decayed manure, where

the position is very exposed and sunny. A good half-dozen comprise: *Anrea* (golden-yellow), *Celeste* (rich lavender, set off by orange-coloured beard), the early-blooming *Florentine Iris*, *Gazelle* (the falls rich lavender, veined with white, suffused and variegated with lavender), *Mme. Cherean* (white, with an edge and feathering of violet), the beautiful *Dalmation Iris* (lavender, tinted with purple on the falls), *Queen of May* (very beautiful, with its shades of rosy-lilac), and *Victorino* (white standards, blotched with bluish-purple, the falls violet-purple, veined with white). These, if good plants are put in now, will bloom fairly well the coming summer, but at least three years must elapse before they flower in perfection. On your border would also succeed the early spring-flowering *Iris reticulata* (the flowers deep-purple, and very fragrant), *English and Spanish bulbous Irises* (both giving a great variety of colours). The *English Iris* is really a Spanish species (*I. xiphoides*), and the flowers are large, broad in the segments, the colours varying from white to self purple. The bulbs will thrive in any light sandy soil, and increase quickly. The *Spanish Iris* (*I. xiphium*) blooms rather earlier than the preceding, the flowers also have narrower segments, with colours ranging from blue to quite a bronzy tint. The bulbs also succeed well in light sandy soil. *I. Kempferi*, which blooms in late summer, must have moisture, and is a beautiful Iris in its variety of colouring for planting at the margin of a stream or pond side, like the graceful *I. sibirica* (the *Siberian Iris*). A lot of beautiful little bulbous kinds, *I. histrio*, *I. histrioides*, and *I. Bakeriana* are in beauty now, and are very useful to grow either in pots or the open.—C. T.

5590.—**Plants for a border.**—You may have a choice selection of hardy plants, pegged-down *Roses*, *Gladioli*, *Dahlias*, such *Lilies* as *L. auratum*, *L. speciosum*, and *L. tigrinum*, the last two mentioned autumn-flowering, *Michaëlas Daisies*, *Ploxes*, *Delphiniums*, and similar things; see reply to 5589. The *China Roses* would look well in this position.—C. T.

USEFUL "CARPETING" PLANTS.

TUNICA SAXIFRAGA.

This little plant is not often seen in gardens, perhaps because its place and use are not so obvious as those of more showy things; but rightly employed it is a pretty and useful plant. It does well in bare, poor ground, and is very handy for carpeting over hulbs. Where the *Meadow Saffrons* are grown in borders (their rich place being, of course, in Grass), there can be no better plant to cover the space they leave bare before and after flowering. The bushy, rather wiry nature of the *Tunica* flower-stems

Tunica saxifraga.

gives just the support needed by the *Colchicums* whose heavy flower-cups, lacking the friendly support of their natural ally, fall over before their beauty is past, and present a miserable appearance, lying flat upon the ground. R.

5581.—**Planting Dahlias.**—You cannot possibly manage to have *Dahlias* satisfactory for sale from old roots without a greenhouse or frame. To propagate cuttings in early spring, however, you may give them an early start by plunging them in a heap of ashes or hot manure by a sunny wall, keeping them well watered. Divide

the old roots and plant out in beds or borders from 3 feet to 4 feet apart in May. When a foot in height place a stake to each plant to keep the wind from breaking it.—P. O. D.

5583.—Plants for a wall.—The *Pyraeantha* is a very ornamental wall plant, especially in winter.—E. H.

—As you wish for plants to look green and bright through the winter months too, I am afraid you will be disappointed, as you omit the plant of all others looks best in winter—namely, the Ivy. You have a choice of the Virginian Creepers, but these are deciduous. They were, however, very brilliant in the autumn with their gay crimson-coloured leaves. Perhaps you could coax *Azora microphylla* into good growth. Its abundant glossy foliage is very pleasing, but it wants a rather sheltered spot; at least, during the past few winters the plants have got much cut about. *Bignonia radicans* is pleasing against a sunny wall, and under such conditions blooms fairly freely. *Clematis luckmanii* or *C. montana* are fine, the latter quickly mounting and producing a wealth of white flowers in early May. Attend to the shoots in spring, removing the weaker ones, but trim in all those that are rigorous, as these bloom the following year. *Jasminum nudiflorum* blooms throughout the winter, and might be planted, but it flowers without the leaves. Then you have a choice of Honeysuckles, Climbing Roses, especially the beautiful *Gloire de Dijon*, exquisite tumbling over a gable, and the Vines, the *Lalanssa Grape* in particular, its leaves turning to splendid colours in the autumn.—C. T.

5558.—Best annuals for small gardens.—*Godetia* The Bride and *Lady Albemarle*, *Candytuft* mixed, *Chrysanthemum* (Tricolor), *Bracing* Larkspur, *Linum rubrum* (Scarlet Flag), *Nasturtium* Fine Toothed mixed, *Scabious* mixed, *Sunflowers*, *Mignonette*, and *Sweet Peas*.—E. H.

—*Linum grandiflorum rubrum*, *Empress Candytuft*, *Shirley Poppy*, *Neurophila ludgisi*, *Rocket Larkspur*, and *Godetia Lady Albemarle* or *The Bride* would be a suitable selection, all of easy growth and productive of a full crop of blossom.—S. P.

I have named twelve good bright annuals; Marigolds, especially such a showy variety as *Orange King*; *Carexopsis bicolor*, *Candytuft*, *Cornflower* (*Centaurea cyanea*), *Clarkia elegans*, *Chinese Pink*, *Eschscholtzia*, *Godetia*, *Sunflower*, *Linaria*, *Linum* *Douglasi*, *Lupines*, *Mignoeette*, *Nasturtium*, *French Poppies*, and *Sweet Peas*. You may choose eight out of any of these, all being very beautiful hardy annuals, readily raised from seed sown in the open in March or April. Be careful always to thin out well, so as to leave each plant sufficient space to develop satisfactorily.—C. T.

INDOOR PLANTS.

5562.—*Begonias* (tuberous rooted) from seed.—The process of raising these plants from seed has been repeatedly and minutely described in back numbers of GARDENING. As the seed is very minute it must be sown on a very finely sifted surface of light rich soil—leaf-mould that has been previously well-baked is best—and the pots or pans be placed in a steady moist heat of 65 degs. to 75 degs. It must also be kept moderately and evenly moist, and shaded from direct sunlight. It is also important that the drainage be extra free, and the soil need not exceed 1 inch, or 1½ inch, in depth. Cover each pot or pan with a sheet of glass to check evaporation, and as soon as the seedlings appear these must be gradually tilted until they can be dispensed with altogether. Prick off the seedlings singly, into other pans or boxes of fine light soil, when in the first "rough" or proper leaf, robex them as soon as they begin to touch each other, and finally pot them singly, or harden off and plant out-of-doors in June. If the plants are to bloom the same year the seed must be sown in January or February, and artificial heat will be required until the beginning or middle of May. Or you may sow in May in the greenhouse, and keep the little tubers over till the next season.—B. C. R.

5597.—Uses of a propagator.—It is the steam which causes the injury to the leaves of your "Geraniums." They do not like so much moisture in the air which surrounds them. You can raise plants from seed of all the subjects you mention in the propagator, but if you have no greenhouse you had better raise the seed at the beginning of April, as such young seedling

plants require a warm, close place after they are taken out of the propagator. If you sow the Sweet Peas in pots at once you may raise them in a sunny window. Yes, you must keep the light burning night and day, except when the heat is a little too much, then you may let it out for an hour or two early in the morning and again in the evening.—J. C. C.

5555.—*Ficus elastica*.—Young cuttings taken off close to the stem with a small piece of the old bark, planted in thumb-pots filled with sandy peat, and plunged in a brisk bottom-heat and kept close and shaded will soon root. The cuttings may be put in now or when they can be obtained. I have struck them from single eyes and one leaf, the bud or eye being taken out with a thin slice of bark and wood, a small stick being placed to support the leaf. After the cuttings are planted a notch cut under the bud would have no effect, except in cases where young shoots are withheld, and the notches covered with damp Moss with the view of striking the tops of the plants before removal. This can be done, but it takes more time than cutting off the top and plunging it in a moist hot-bed.—E. H.

GROUPING PLANTS IN GREENHOUSES.

EXCELLENT results as regards effect can be made in almost any greenhouse, conservatory, or fernery by a group or groups of Ferns and other plants (see illustration) arranged on the floor of the building. A corner or centre bed

Group of Ferns and other plants in a greenhouse.

can be so set off to great advantage in this way, and the plan gives a lighter and more natural appearance to the plants than when they are all arranged on still stages, &c. B.

5547.—*Growing Heliotropes*.—These delightfully fragrant plants require rather liberal culture, yet with a fair amount of fresh air and sun to solidify the growth. With suitable treatment, young plants from cuttings struck, say this month, and kept near the glass in a light house, will bloom abundantly at about a foot in height from the rim of the pots, in July or August of the same year, and such plants always produce far finer heads than old and starved examples. As good a system as any is to strike the cuttings in the early spring, in heat, placing several together in 5-inch pots. When well rooted put them off singly, and as soon as rooted out pinch out the points of each. When fairly in growth again shift into 5-inch pots, or a few of the strongest into 6-inch size, using good loam with half the quantity of leaf-mould or old hot-bed manure and some sand. Loop up the shoots to a next central stick as they grow, and give weak liquid-manure once or twice a week when coming into bloom. Autumn-struck cuttings may be lowered earlier, of course.—B. C. R.

5473.—Plants for a north greenhouse.—A north house is very useful for retarding plants, and for keeping things in bloom after the show is over, but it is not a good growing house. *Chrysanthemums*, *Cinerarias*, *Lilies* of the Valley, and bulbs of various kinds, including *Gladioli*,

all kinds of Ferns will do well, and foliage plants, such as *Dracena indivisa*, *Pan Palms*, *Arklia Sieboldi*, and *Aspidistras*. In summer, *Fuchsias* will do well, as will also *Liliums* of various kinds. If *Lapageria* are planted out in a properly prepared bed they will cover the back wall and the roof.—E. H.

5518.—*Tuberoses*.—If I understand you to have placed the Cocoon-fire around, and not beneath the bulbs, it may be of benefit to them; not otherwise. You may place a few into a heated house at once, even near the pipes if you wish some early; but for August and September blooming they had better rest where they are. Great care should be taken not to have them too moist before the roots are active, or they will rot at the base.—P. U.

5427.—*Heating a brick pit*.—Yes, a well constructed one is as good a method of heating a small pit as any other, and better than a small hot-water apparatus, for this reason, that with a proper furnace and the draught well stopped, the fire will remain night twice or three times as long as in a small boiler. Nine inches square (inside) is a very suitable size for the flue; it should be covered with what are termed "quarries," or flat tiles 12 inches square and about 2 inches thick. Unless anthracite coal is procurable, in which case an ordinary horizontal furnace, like that of a washing-copper, will do, the best plan is to make a deep square one, say 18 inches deep, and 3 inches or 10 inches square, with the feet-

floor at the top, and ash-pit and draught-regulator at the bottom. A fire in such a furnace, when filled up with coke, and the draught stopped below the fire, will remain alight for eighteen or twenty hours easily. I recently constructed an excellent double one, the lower one being built as described above, with a return above consisting of 6-inch socket earthenware pipes (glazed). A passage direct from the furnace into chimney was arranged (as well as the other), and a damper fixed in it; when the fire is lit this is opened, and as soon as the fire has burnt up and the chimney become warm it is closed, and the draught forced to pass through the flue.—B. C. R.

5514.—*Crinum bulbs*.—As the bulbs name from India they are no doubt varieties that require a stove temperature. In that case your treatment has been right. You may increase the warmth with advantage as the spring advances; otherwise you may continue the same. The greatest danger is in giving too much water while the bulbs are dormant. I do not think you will see much signs of growth until May. There is plenty of time for them to flower in their usual season after that, which is generally in the months of July and August. If they are potted in a moderately light compost a change of soil will not help you.—J. C. C.

5577.—*Making a hot-bed, &c.*—Throw the litter and leaves into a heap mix it, so as to get together. If the latter is very thick, mix it with some of the litter. After it has lain for three or four days turn it over, allow it to lay three or four days more, and then make up. By

this method of management, heat in the hot-bed is not so violent or irregular as when made up at once. Very often then parts of it are dry, and instead of fermenting properly it becomes mildewed, thus the heat in the bed is irregular. The beginning of March is quite early enough to start—in fact, rather too early if the materials named are scarce. Beds made up early require additional linings to them to maintain the heat.—S. P.

5574.—Gas and electric light in a conservatory.—I do not know what you may mean by the word occasionally in reference to the use of gas in a conservatory? It may mean once a week or once a month? I may, however, tell you that some years ago I had charge of a conservatory quite as large as the one you mention, only about 10 feet higher. This was well lighted with gas. Once a week I had to clear the floor of this building all the winter for a certain purpose, and although the gas was usually alight about five hours, the plants were never injured, and none were taken out, only packed closer together round the sides. The ventilators at the top were always left open a little way. I should, however, give the preference to the electric light, as it gives out no injurious fumes, and the light is more beneficial than otherwise to plant life.—J. C. C.

—Not the slightest if the gas-jets are not near the plants, and they are not used too often. The mischief is when gas is constantly burnt, thus drying up the air. But electric light is better. It is less drying, cooler, and not so glaring.—C. T.

5550.—Heliotropes from seed.—You can raise these easily enough in a frame over a hot-bed at 70 degs. to 80 degs. in March or April, or possibly in a cool frame or greenhouse in May, but without heat it is no use to sow yet. I have got them up by thousands in a propagating-house in March, but unless the seed is quite sound and fresh it will not grow, however carefully treated, and as it is a thing that there is but little demand for, you are very likely to get old seed.—B. C. R.

—Heliotropes may be raised from seeds in an ordinary garden-frame, especially if there is a mild hot-bed under the frame. Sow now if there is any warmth. If there is no heat beyond the sun's warmth, better delay sowing till end of next month.—E. H.

5444.—Making a propagator.—Yes, it is best to support the tray. This can be done by placing two strips of wool lengthways inside, and the same depth as the tray. The perforated sheet will then be quite level. You may call the tray which holds the water a tank if you like, but if you think that a greater depth of water would be better you are mistaken, for two reasons, one of which is that the more water there is to heat the more oil you must burn; the other reason is that the more water there is in the tray the more condensed moisture there is above it, and which will be found to be troublesome by causing scallings or cuttings to damp off. With regard to the size of the lamp, mine is 8 inches high, with a single wick half an inch wide. The box should rest level on the ground, and the opening, which enables the operator to take out and replace the lamp, should be closed when the lamp is burning. The bottom of the tray should be 9 inches from the side of the box, and 8 inches or 9 inches above the Cocoa-nut-fibre. You can have more space than this above if you like, but the more air there is to heat in this space the more oil is consumed to maintain a suitable temperature.—J. C. C.

—Yes, you had better support the perforated zinc by two strips of wood fixed across beneath it, if to carry any weight. A lamp with a 1½-inch wick will give plenty of heat for a propagator 1 foot 8 inches by 1 foot 6 inches. Of course, provision must be made for admission of air to the lamp from beneath, or it will not burn properly. I always fix my propagators on legs at a moderate height from the ground, and block up the lamp beneath to the proper height.—B. C. R.

5500.—Treatment of Streptocarpus.—In the early stages these plants, when raised from seeds, require the same treatment as Gloxinias, i.e., they require a warm-house or pit, and shade. When well-established they may be grown in a warm greenhouse. At present most cultivators use chiefly peat and sand, but it will probably be found when their culture becomes more general that equally good, perhaps better, results will be obtained by using

a richer and rather heavier compost. Sow the seeds in a pot or pan in moist soil, cover lightly with silver sand, and cover with glass. When the seedlings are large enough to handle, prick off in other pots or pans 1 inch apart, and when some growth has been made, put either singly or three in a pot; 5-inch pots will be found large enough for growing them in. They may be propagated from leaf-cuttings in the same way as is done with Gloxinias, but they seed freely, and any kind of propagation will only be required to perpetuate particular varieties.—E. H.

5266.—Coleus cuttings.—The Coleus is a most easily propagated plant from cutting. The time to take them is the spring, and they root quickly when put separately in small pots filled with a light soil and placed in gentle warmth. When rooted put them on, and as they make comparatively quick growth, one must be careful not to let them get pot-bound. They must have a warm greenhouse temperature, certainly not less than about 55 degrees in the winter months. It is useless trying to keep them in a cooler house, and when this is not possible propagate a great stock every spring from cuttings, throwing away the old plants when past their best. Give them a light position to bring out in all its fullness the full richness of the leaf colouring, which is in many varieties remarkably handsome, especially those approaching a self colour. The best soil for the Coleus is one made up of well rotted turf, a little thoroughly decomposed cow-mannure, mixed with sufficient sharp silver sand to keep the compost open. Put firm, and when the plants are in full growth weak liquid-mannure may be given with advantage. It is a great mistake to cold the plants up, so to speak, in the summer months, as unless they get air and light in moderation, the growth will be tall and lank, and the leaves of dull colour.—F. P.

—These will root at any time, but best in the spring and summer. A light sunspot and strong, moist heat will strike them freely. If they rot under it they are either at a joint or rot; any piece of young wood will root with remarkable freedom, so will other wood. A little sharp sand at the base, a moist and partially shaded temperature of 65 degs. to 80 degs. will ensure success.—F. P.

5406.—Cytisus cuttings.—Cuttings of the ends of the young shoots 2 inches or so in length, just getting a little firm at the base, will root under a bell-glass in sandy loam and leaf-mould in about equal parts, with a layer of about half an inch of clean sand on the top of each pot. Must be kept close and shaded from bright sunshine; the bell-glasses to be wiped quite dry every morning. A temperature of 50 degs. to 60 degs. will be suitable. There are generally plenty of good cuttings in April and May or later. If the cuttings are taken in summer they will do in a cool frame.—E. H.

5500.—Chinese Lilies.—Weak and immature bulbs is, I think, the only satisfactory answer that can be given to this inquiry. Some of my bulbs behaved in the same way last year, while others did very well, and all under the same treatment, so that I think it is quite reasonable to suppose that the cause of failure lays in the direction I have indicated. I expect the demand for these bulbs has increased faster than the means taken to keep up the supply, consequently all the stock has not been sufficiently prepared.—J. C. C.

5587.—Azaleas from seed.—If you possess a reasonable amount of patience to wait for the young plants to come up, you will not have any serious cause to regret your outlay, seeing that you will be content if the flowers are suitable for cutting. This they will in all probability be, and no doubt a fair proportion of the plants will be worth growing as pot specimens. The young seedlings are liable to damp off if they are given too much room. Put each one singly when large enough in a 2½-inch pot, and then plunge the pot to its rim in another three sizes larger that is filled with soil. This will keep the soil about the roots more uniformly moist, which will ensure its making greater progress.—J. C. C.

—Unfortunately you do not say if the seed you possess is from the Mollis, Ghent, or Italian section of Azalea. The two first will come good enough from seed, but the last is not so certain. Ghent and Mollis Azaleas seed freely, and cross with the varieties of their respective sections, but a good variety of cotton-wool must be used if you wish to look for.—F. C.

5274.—"Geranium" cuttings.—It is quite early enough to begin striking cuttings of these plants yet, and I always find they do better inserted about the beginning of March than earlier. In the meantime the plants had better be hardened off a little by keeping them moderately dry, and admitting air whenever possible. If any of the tops or side-shoots, about 3 inches long, are taken off and inserted in well-drained pots of sandy loam in three or four weeks' time, nearly all of them will soon root in a temperature of 55 degs.; but they must be kept moderately dry, and, if possible, near a hot-water pipe or fire till rooted. Potted singly in March or April, they will make nice little flowering plants by June. Keep the old plants dry for a time, and when growing again, shake nut and repot, and they will bloom beautifully all the summer.—B. C. R.

—It is very easy to propagate Pelargoniums from cuttings made from old plants started in gentle warmth, but they should not be young or succulent, otherwise they are apt to damp off quickly. Take the more ripened shoots, cut them just under a joint, and put them round the side of forty-eight or 5-inch pots, filled with a light soil, or they may be put into separate small pots, placing them in a warm frame or a hot-bed, or some similar place, to induce quick rooting. When struck, if in the forty-eight sized pots, pot them off separately, and from thence onwards pot them on when the pots they are in at present are filled with roots. If the cuttings are good in the first place, and the plants are grown up carefully, they will be ready to go out in early June, although not so free as those from cuttings struck in the previous autumn. The old plants will bloom well in the summer, and in many gardens they are made good use of, giving a remarkably free display of their showy flowers.—C. T.

5279.—Starting Begonias.—"An Amateur" will be able to manage this very well with a frame, seeing he does not require them earlier than for bedding-out in the summer. The plan, as suggested, of putting them in pans or boxes and placing in a warm shelf in the dwelling-house is excellent. Do it now, and then transplant to the frame early in April. If you can manage a very little heat in the frame from manure and decayed leaves it will be better. I should transplant into the frame in preference to potting; it is safer as regards water, and saves much trouble. They will lift well if given a good soaking the day previous. Your idea is excellent all through, and there is hardly any subject more pleasing or easy to grow for bedding out.—P. U.

—Tuberous Begonias are not so troublesome to start into growth as many suppose, judging from inquiries about them. You could very well follow out the plan you propose, which is really the only feasible one, as you have no artificial heat whatever. They will start slowly but surely, taking care, however, that they are not exposed to frost. When they have made a few leaves, pot off using a rich, moderately light soil. Good loam, with a fine proportion of leaf-mould, forms an excellent compost for them, not forgetting to drain the pots well. Syringes also every day if possible, but do not expose the young leaves to the bright sunlight, which scorches them. As they get established, expose them to the air, and before being bedded out they may be well hardened off in a cold frame. But as you possibly know well, frosts are fatal.—C. T.

5342.—Gloxinias from seed.—Sow the seeds in the hot-bed in spring, or in a warm house. Prick off into pans of light soil when large enough to handle 2 inches apart, and when the leaves meet place in single pots. During growth they must be kept close and shaded in a warm pit or house. The seeds are very small, but if they are now the seeds grow freely. Drain the pots well, and press the soil, which should be light and sandy, in firmly. Water the soil before sowing the seeds, and cover lightly with silver sand. Place a square of glass over the top of the pot, and plunge in bottom-heat.—E. H.

5300.—Plants for a greenhouse.—Geraniums, Fuchsias, Hydrangeas, Cytisus, Camellias, Myrtles, Oleanders, Tuberos Begonias, Agapanthus umbellatus, Gladioli, and Mignonette, are all easy to manage, as are also the common Dutch bulbs for early blooming. These should not be forgotten.—E. H.

ORCHIDS.

DENDROBIUM LEECHIANUM.

This is a hybrid raised between *D. noble* and *D. aureum*, and its flowers have a good deal of the perfume of the last-named parent still left, which adds materially to its value as a winter bloomer. I have received some flowers of this plant from "Reuben Bryan," asking if they are true to name, and if I will give him some notes upon the culture? In this case I can speak from practical experience, having had a lot of plants of this variety under my charge, along with its near relative, *D. Ainsworthi*, which appeared at the same time, and which is from the same cross. Now the variety *D. Ainsworthi* I consider as superior to the form now before me; but the best and largest and finest of all this set is the Veitchian hybrid named *splenditissimum*, which takes first rank amongst all the varieties which have been obtained from *D. noble* and *D. aureum*. I will, however, here confine my remarks to the *D. Leechianum*. It is a very variable plant, indeed, it approaches very near to *D. Ainsworthi*. Indeed, it is natural enough that it should run into that form, but one peculiarity in *Leechianum* is that the base of the lip closes over the column, whilst in *D. Ainsworthi* the lip, although erect, does not close over it, but it is quite exposed, and it is also usually reflexed at the tip, as in the flowers before me. The sepals and petals are white, and a rosy-pink, and the lip is stippled with the same colour, and it has in addition a broad blotch, bright-crimson on the disc, with numerous radiating lines running out from it. The growth is somewhat in the way of *D. noble*, and it wants treating very much in the same manner, but it likes more warmth when growing, and it will not stand so much drying or so much cold treatment. It likes a nice moist warm atmosphere, with plenty of light and air. When the growth is finished it may be removed to the cool end of the Cattleya-house, and be kept dry for a time. It flowers at this time of the year, and the flowers remain long in beauty. This variety will make a wonderful show if you have the strong growths you speak of upon it, because you may reasonably hope to have a very much larger number of flowers next season than you have this.

MATT. BRIDGEMAN.

5519. — **Orchids for a greenhouse.**—Several Orchids may be grown in a greenhouse, and the most useful of all is *Cypripedium* insignis, the familiar Lady's Slipper, which is a really beautiful flower. This may be grown practically without artificial heat the whole year. The plants may be placed in a cold shady frame during the summer months and brought into the greenhouse in the autumn, where they will bloom freely throughout the winter months. The great charm in *Cypripedium* is that the flowers are not touched by fogs—at least, less so than the majority of Orchids. The brilliant orange-scarlet flowered *Ailu maritimum* will succeed in the greenhouse, and of other kinds you may grow are: *Cologyne cristata*, which blooms at this time; *Lycaste Skinneri*, of which there are many varieties, the flowers in some instances splendidly coloured, especially the lip; *Masdevallia Veitchi*, *M. Harryana*, and the pretty little pure-white *M. luyarensis*, one of the most useful of all winter-flowering Orchids. *Odontoglossum crispum* (Alexandria), is another useful species, the flowers varying greatly in individual varieties, but even the purest forms are beautiful. It is an easily grown Orchid, and thrives in quite a cool temperature. *Lycaste Skinneri* is another useful species, very variable in colour, especially on the lip, which is sometimes deep-crimson, or pink-rose. You might also with care grow *Oncidium tigrinum*, a beautiful species, the flowers as richly scented as the Violet, and very showy, the lip yellow, and the sepals and petals barred with deep-brown on a similar ground colour. *Sophronitis grandiflora* in shallow pans where the light would make a bright display of colour, and the violet-scented and handsome *Zygopetalum Mackayi*, may also be included. This has large flowers on a strong spike, the lip veined with a bluish colour on an almost white ground. All the Orchids mentioned may be grown, and they do not

require much heat. But you may also have the hardy *Cypripedium spectabile* in pots. This is a beautiful flower, far more so than many of the heat-loving kinds, the flowers rose and white. Good pots of *Orchis foliosa* also are very fine, and it is quite worth growing in the greenhouse, also *Dica grandiflora*, the showy scarlet flower of the Cape of Good Hope.—C. T.

HOUSE & WINDOW GARDENING.

MOUNTAIN CLEMATIS (C. MONTANA).

As a wreathing or garlanding climber for early summer blown around a house window or in a porch nothing can approach this lovely Clematis. Its beauty is best seen when trained loosely and freely; nailed tightly and flat against a wall, the many graceful forms it is willing to fall into are lost. The annexed illustration shows the plant growing in a natural and unrestrained manner. Anyone who wishes for a beautiful flowering climber to

Mountain Clematis (C. montana) around a window.

adorn the house cannot do better than plant the Mountain Clematis.

5515. — **Wireworms.**—In reply to "Alpha," wireworms have a hard, wiry skin of a dull yellow, or coppery hue, and they vary in length from half an inch to nearly an inch. They are very fond of French Beans, and when I built my Tomato-houses, knowing the land was infested with wireworms, I planted rows of French Beans between the rows of Tomatoes. The Tomatoes did well, as the Beans protected them till they got strong, but of course the Bean crop was a failure. Whenever the Beans were uncovered, half-a-dozen wireworms of different sizes, from the tiny, thin insect to the large, fat fellow, would be found embedded in each Bean. To look at a wireworm when suddenly unearthed one would think they had no energy to eat Tomatoes or any thing else; but they must wriggle their hard, shining bodies through the loose earth at a pretty good pace, and they will soon have a hole through a French Bean, or up the stem of any plant they like. But they do not stop long with a plant after it begins to wither. This is why they are so destructive. They must continually have fresh food.—E. H.

RULES FOR CORRESPONDENTS.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow the rules here laid down for their guidance. All communications for insertion should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 37, Southampton-street, Covent-garden, London. Letters on business should be sent to the Publishers. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Unanswered queries should be repeated. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, they cannot always be replied to in the issue immediately following the receipt of their communication.

Answers (which, with the exception of such as cannot well be classified, will be found in their different departments) should always bear the number and title placed against the query replied to, and our readers will greatly oblige us by giving, as far as their knowledge and observations permit, the correspondents who seek assistance. Confessions, hints, and remarks vary so infinitely that several answers to the same question may often be very useful, and those who reply would do well to mention the localities in which their experience is gained. Correspondents who refer to articles inserted in *GARDENING* should mention the number in which they appeared.

- 5514. — **Autumn-sown Onions.**—When should I plant out autumn-sown Onions?—G. SHERBURN.
- 5515. — **Manures for Evergreens.**—What are the best artificial manures for Evergreens?—J. M. S. P.
- 5516. — **Perennial plants.**—What perennial plants remain longest in flower during the season?—A. M. S. P.
- 5517. — **Manures for Hops.**—Will someone please tell me the best artificial manures for Hops?—H. FURKES.
- 5518. — **Propagating Gardenias.**—Will someone kindly advise me the best plan of propagating Gardenias?—J. S.
- 5519. — **Mountain Ash.**—Will someone kindly tell me if the Mountain Ash will grow at a great elevation? Can it stand a rigorous mountain winter?—A. H. M.
- 5520. — **New Chrysanthemums.**—Will "E. M." kindly give the names of the best twelve new Japanese Chrysanthemums for exhibition purposes?—J. K. CARLIDE.
- 5521. — **Peat Moss-litter for a hot-bed.**—I should be much obliged for information as to the best way of making a hot-bed with Peat Moss-litter from the stable?—P. W.
- 5522. — **Soil for Tomatoes.**—Will anybody please tell me whether turf from the top of a marl-pit would do in pot Tomatoes with, and if there is much goodness in it?—P. L. P.
- 5523. — **Box eelings.**—Would someone please to inform me what is the best time to put a Box eelings to a border, in the far north, subject to late frosts?—H. SHERBURN.
- 5524. — **Catching Voles.**—Will anyone kindly inform me what kind of bait to use for catching Voles? I have tried several kinds, but cannot catch any of them.—H. L. W.
- 5525. — **Begonias flowering.**—I shall be much obliged if anyone will inform me if Begonias (single) sown the second week of February will flower the same season?—A. M. S. P.
- 5526. — **Carnations out-of-doors.**—Will someone kindly give me full particulars as to the soil for and appropriate treatment of Carnations to be placed in an outside bed in March?—H.
- 5527. — **Chicken manure.**—I should be glad to know its manorial value, how it should be applied, and when? My garden is rather a small one, and contains several Rose-trees.—A. Z.
- 5528. — **Plants near the glass.**—I so often see the advice in regard to potting plants, &c., to keep "near the glass." Will someone please to inform me what distance from the glass that means?—J. P. P.
- 5529. — **Seeds of Ceanothus, &c.**—I should be glad of any information respecting the treatment of seeds of *Ceanothus* Dampierii, *Ceanothus* purpureus, and *Boronia* megalantha?—H. SHERBURN TO GARDENING.
- 5530. — **Powl manure.**—Is it assured from how a proper fertilizer for a small garden? A neighbour of mine has offered me a quantity, but I am afraid that, being fresh, it would be too strong. Is this so?—W. L. BROWN.
- 5531. — **Good King Henry.**—Will someone kindly give directions for cooking Good King Henry? This is a vegetable little known in the south, and much extolled in Gloucestershire some time back.—AN OLD SUBSCRIBER.
- 5532. — **Aralis Sieboldi.**—I have a plant of this that got touched with frost, and it is very tall. Can I cut it back about 15 inches, and strike it, and if so, how would it do best, in water or soil? I have no stove.—S. P.
- 5533. — **Moles in a garden.**—My garden is overrun with Moles. I have tried traps, but cannot catch many. Will anyone kindly tell me of any poison or other remedy that I could use by putting it in their runs?—S. H. P.
- 5534. — **Preserving putty.**—What can I put the putty over with to prevent drip and the putty from rolling? Is there anything to mix in with putty to render it more durable for the roof of a greenhouse?—HEXAR KEATLEY.
- 5535. — **Unsatifactory Hyacinths.**—My Hyacinths, both in pots and glasses, are very short, quite stunted, in fact; the flower is scarcely above the leaves. I wish to know the reason of this, and how it can be prevented?—L. W.
- 5536. — **Myrtle against a house, &c.**—Will someone please to tell me if a Myrtle will grow against a house facing south, in one of the Midland Counties? Would the Myrtle do on the north wall, and a fruit-tree on the south?—E. J. W.
- 5537. — **Fruit-tree in a north-east aspect.**—Will someone please to tell me the best fruit-tree to grow

against a house with north-east aspect that will not have any sun after 9 a.m. Locality, lower part of Bucking. hamshire.—B. J. W.

5638.—**Crotons and Dracenas.**—Would highly-coloured Crotons and Dracenas live during the summer months in an unheated lean-to greenhouse facing south, in which Crotons do well? Situation, Queenstown, South of Ireland.—C. A. G.

5639.—**Fish refuse.**—I wish to know how to dry and make fish refuse into powder or paste, or in any way to make it so as to give it to plants of Geraniums, Roses, and Chrysanthemums, and what quantity is sufficient to give them?—G. B. B.

5640.—**Truest thermometers.**—Which thermometers tell the truest, mercury or spirit? What would be the price of a reliable one, and in what part of the greenhouses, heated with a coke stove, would be the best place for it?—J. F. P.

5641.—**China Asters in pots.**—Into what sized pots should China Asters be first potted into, and will they require a second shift; if so, into what sized pots? In planting into boxes and out-planting, what distance apart ought they to be?—J. F. P.

5642.—**Gold-fish in a glass vase.**—Would someone please to state how Gold-fish should be properly cared for which are kept in a glass vase, and to what age they usually live? The ones I have being about 2 inches in length now.—H. B. HULLS.

5643.—**Potting Lobelias.**—In potting Lobelias from the seed-pans what sized pots should be used? Will they require a second shift; if so, into what sized pots? If planted into boxes out of seed-pans, at what distance should they be planted?—J. F. P.

5644.—**Culture of Olea, &c.**—Will anyone please to give me some hints as to the cultivation of the following plants—*Olea*, *Chenopodium*, *Piptanthus*, *Uapenalis*, and *Olearia* *Hassii*? Could I grow the former in a cold greenhouse?—TULLYALLT.

5645.—**Gold-fish out of doors.**—Will anyone kindly tell me if Gold-fish will live in an ornamental basin out-of-doors, and if so, what is their proper food? Any other hints as to their management, both in and out-of-doors, will oblige? Climate mild.—G. A. G.

5646.—**Dissolving bones.**—I wish to know how to dissolve bones into a powder? I have a quantity every week to dispose of. Which is the best way to give it to "Geraniums," *Fuchsias*, *Roses*, and *Chrysanthemums*, and what quantity to give them?—G. B. B.

5647.—**Potting off Stocks.**—In potting off Ten-week Stock into what sized pots should they be potted? Will they require another shift before planting out? If so, into what sized pots? In planting out of pans into boxes, at what distance should they be planted?—J. F. P.

5648.—**Cyclamen not flowering.**—I have a Cyclamen with only four leaves, and no sign of blossom, one leaf measuring fully 8 inches across. All my others have done well under exactly the same treatment. Will anyone kindly tell me the cause and cure?—J. F. P.

5649.—**Cutting down Ivy.**—What is the best time to cut down Ivy on a wall from which the brambles protrude from 1 foot to 2 feet? I would like to cut it off close to the wall, but should not like it to look bare all the summer. Would it be wiser to cut it now?—INQUIRA.

5650.—**Dressing a lawn-tennis ground.**—There is mossy stuff grows all over the top of my lawn. Will any reader suggest anything so as to get rid of it? And the Grass gets bald. Also what is the length and breadth of the white lines for lawn-tennis?—B. M. C. Y.

5651.—**"A Loughborough" boiler.**—Will anyone who has given the "Loughborough" heating apparatus for hot water in a fair trial kindly say how it has answered, and if it is a boiler is sufficient to heat three sides of a greenhouse, 10 feet by 8 feet, with 3 inch pipes?—JANE ARDRA.

5652.—**Plants for a shaded border.**—I should be glad to know what would be the best to plant in a border that is shaded by overhanging trees, and hardly gets any sun at all. I should prefer plants that would flower during the summer. Would *Lilies* or *Glaucium* suit this position?—T. C.

5653.—**Hedychium Gardenianum.**—I have a plant of this in my conservatory. Keep it in a cold greenhouse. It did not bloom last summer; is now dying off. Should I cut off the withered stalks, and will it break from the bottom again? I potted it and fresh potted it about two months ago.—HIBERNIA.

5654.—**Short-stalked Violets.**—Can anything be done to make the minimum single Violets grow with longer stalks? I have abundance of flowers, but most of them are almost too short to pick. The roots were thinned out last year, but had been neglected before. The Violets are in an ordinary border facing east.—JARDNA.

5655.—**Climbing Roses and Hops.**—I have some climbing Roses and Hops on my verandah, and every spring and summer I am troubled with the greenfly; they run up and down with water, which is a great nuisance and trouble. Will someone please tell me what is the best thing to do to prevent it coming?—H. BULLOCK.

5656.—**"Marguarita" Carnations.**—Would anyone oblige me with some information concerning "Marguarita" Carnations for winter blooming—whether they bloom satisfactorily, the fact that the seed should be sown, their after-treatment, and the minimum temperature in which they will expand their blossoms?—R. B.

5657.—**Manures for a kitchen garden.**—It would be a boon to myself and many gardening amateurs if some expert would kindly give a list of manures, &c., most beneficial in the various groups of kitchen garden crops, such as Peas, Parsnips, Lettuces, and so forth, with information as to amount to be used, and how and when to use it.—H.

5658.—**Violets in winter.**—I wish to have advice as to the best manner of getting a continuous supply of Violet flowers during the winter? Which is best, to use frames or an erection such as the "Amateur's forcing house," and if frames, how can some heat be applied? I have only a small suburban garden in Edinburgh.—A. E. M.

5659.—**Getting rid of ants.**—Will anyone please to enlighten me as to the best means of getting rid of ants, which have infested my stove-house? I fancy they were imported last summer in peat-soils, with which tinned seeds as well as a groundwork for Ferns. They are a great nuisance, and doing much injury to several of the plants.—F. BERN.

5660.—**Treatment of a Cyclamen.**—I have a very good Cyclamen plant with grand blooms last year. This year it bud-died early for blooming again, but after it had been in bud some time the buds died off, and there is no prospect of any flowers this year. Will anyone kindly tell me the cause and cure for this?—NORMY LINCOLNSHIRE.

5661.—**Height of Chrysanthemums.**—Would "Mr. E. Molyneux" kindly give me the average height of the following Chrysanthemums: Viviani Morel, Sunflower, E. Molyneux, Stansted White, Florence Davis, Conite F. Lurani, Excelsior, W. Seward, Etaiie de Lyon, Lord Brooke, W. H. Lincoln, G. C. Schwabe, and Mlle. Therese Rey?—R. L.

5662.—**Soils for various plants.**—Would someone be kind enough to tell me the sorts of soils required by the following plants, as I have all sorts of soils to pot them with? *Ranunculus*, *Roses* in pots, *Arums*, *Polygoniums*, *Fuchsias*, *Azaleas*, *Camelias*, and *Cacti*. I am very anxious to give the plants their proper soils or proper mixture of the same.—S. E. W.

5663.—**Window-boxes.**—Will someone kindly suggest what flowers I should plant in my window-boxes to make a good bloom in summer? They are in a western aspect, and get a great deal of wind. I would like to have something to climb round the windows, also lower plants for the centre of the boxes? I have tried "Geraniums," but it was too windy for them.—K. J. H.

5664.—**Planting Apples-trees.**—Would someone kindly name about one dozen sorts of Apple-trees to be planted now, in two squares of a large kitchen garden? The ground round them to be let out permanently in Grass in a year or two. I want very early and late sorts for "dessert," as we have a mid-season crop at present. Locality, South of Ireland.—J. V. WIZ.

5665.—**Rats in a garden and stables.**—Will someone kindly give me a receipt for destroying rats in a garden and stables? They are very numerous, and destroy many vegetables. I am afraid to use poison, because I keep a horse and pigs. I may say I have tried putting tar in their holes, also putting flour and plaster of Paris mixed for them to eat, with no effect.—A. B. C.

5666.—**Pruning Roses.**—The excellent article recently in *GARDENING* on pruning Roses was just too late for me, as only a day before some of mine were pruned. What is likely to be the result, and can anything be done to counteract any harm already done? The Roses were free-growing climbers on the supports of a verandah, facing east, but well protected from cold.—JACLAND.

5667.—**A window screen.**—It is proposed to block out the view from an N.W. window with plants. Boxes hardly promise screen enough. Would a double window—i.e., a miniature conservatory—cool much more? I should be grateful for practical suggestions on the subject. I have a hard man who coils up the string, &c. What plants would thrive in such a place, and how should it be heated?—S. S.

5668.—**Azaleas losing their leaves.**—Will someone kindly inform me the probable cause of my Azaleas dropping their foliage? I have some just coming into flower, and hardly any foliage on them. The leaves go brown and fall off. I should be very glad of information as to remedy it in the future? I keep them in a greenhouse, but only have a fire in frosty weather.—F. BARNER.

5669.—**Pruning Climbing Roses.**—Will "J. C. C." or "P. U." advise in the pruning of the following Climbing Roses under glass: *Niphetos*, *L'Idéal*, *W. A. Richardson*, *Gloire de Dijon*? Should they be cut right back like *Marschal Niel*? The *Niphetos* last present like a single rod, 20 feet long, but not as thick as a quill. It is sitting about 40 buds, and I am specially anxious to do what is best to it.—ADAM.

5670.—**Managing a propagator.**—I have made a large propagator, about 4 feet by 12 feet. I keep half an inch of water in the tank, and there are 3 inches of fibre-wool in which the pots are buried. There seems to be a great excess of moisture in the top box, which threatens to damp everything off. Can someone suggest a remedy? Should holes be bored in the sides of top box, or should the tank be kept empty at times?—AMARANTH.

5671.—**Carnations under glass.**—I am much obliged in "E. K." and "P. U." for their answers to my queries. Would either of them kindly tell me how to lower Carnations successfully under glass? I potted some up from the beds in November, hoping they would go on flowering through the winter, but they have only made long weakly growth, some 8 inches to 10 inches in length, but no flowers. What is the reason?—INEXPLICABLE.

5672.—**Plants in a conservatory with Ferns.**—Will someone kindly give me a good list of plants to grow in a conservatory with Ferns? The house is situated in a warm corner, facing south-east, and is heated with hot-water during the winter. I wish to keep up a good accession of plants and bloom. Is it a bad plan to let plants stand on a stage exactly over the hot-water pipes, and if so, what can be done to improve matters? The stage cannot be moved.—A. H.

5673.—**Eucharis amazonica.**—I have some *Eucharis amazonica* bulbs, and would be very glad of any information as to their treatment? I have some just potted them in 32 sized pots, with three bulbs in a pot, using a compost of good loam two-thirds, and one-third of well-decayed leaf-mould, with just a dash of sand, and have placed them in a house in which Tomatoes are grown during summer, and is kept up to 60 degs. by day, falling to about 45 degs. at night. Is my treatment of them right?—C. H.

5674.—**Plants for a centre bed.**—For the centre bed of my front garden I want to get something out of the best on track of "Geraniums," *Calceolarias*, &c. The aspect is south-east. Last summer I noticed a bed of *Stachys* and *Drinks* flowers. *Begonias* at a little sheltered spot in shade. Would these do equally well with the

had a dry or a moderately wet season, and not rim to tollage like "Geraniums" in a wet season? Lastly, what about the cost, and where could I get reliable plants or bulbs, and when must I proceed?—SACRY JACK.

5675.—**Hydrangea paniculata grandiflora.**—I have bought a lot of *Hydrangea paniculata grandiflora*. The plants are shaken free of all soil, and as I know nothing of their culture I should be obliged for any hints on the same? I want to have some in bloom as early as possible, and others as late as possible. I have a greenhouse that is kept at 50 deg. at night. If I pot a few and take them into heat at once, will they elaud it, or shall I start them first in a cold frame, and take them into heat when the roots begin to fill the pot?—HARTRO.

5676.—**Coxydines and frosts.**—My three *Onoclydine* trees, over 25 feet in height, are badly affected by the unprecedented (here) frost of the 4th of January last, and the leaves have entirely fallen from one, the others are turning brown, and I am very much afraid I shall lose them all. I should be thankful for any suggestions of treatment, whether clipping the extremities would be advisable, or what? Almost all in the island have suffered, and the total loss of them would be felt greatly, as they are a very picturesque feature in the landscape.—GURNEYMAN.

5677.—**Treatment of Chrysanthemums.**—I should be glad if anyone would kindly give me the treatment of the following list of Chrysanthemums? I want them in flower about the second week in November, and as far as I can get them, with four or five flowers to a plant. *Chrysanthemum* *Paul J.*, *Mrs. F. Jameson*, *Primrose League*, *Beauty of Castlehill*, *A. R. Nere*, *Lord Brooke*, *Gloire du Rocher*, *Mr. E. Beckett*, *Beauty of Exmouth*, *Gloire Rose*, *Hamlet*, *William Seward*, *Mrs. R. King*, *Col. W. B. Smith*, *Eda Prass*, *Florence Davis*, *Mrs. Nibset*, *John Lambert*, *G. W. Child*.—C. B.

5678.—**Arbor-vitae hedges.**—Two years ago I planted a hedge of *Thuja Lobbi*, five bushy shrubs, about 6 feet high, in a situation rather exposed to the prevailing S.W. winds. They have increased very little in height, and have lost a great deal of foliage, the lower half of the trees especially being very thin and bare. Is there any possibility of their growing into a good hedge if they were pruned down to half their present height, and when will be the best time to do this, or how should they be treated? Part of the hedge, which is more sheltered from the wind, is doing fairly well.—ROOKWOOD.

5679.—**Mildew on Vines, &c.**—Last year my *Grape-Vines* and *Chrysanthemums* were badly milkewed in a cool-house. The Vines were later on stripped of their bark and coated with clay and tobacco-juice. I am afraid there are signs of the mildew still being about the house, "Geraniums" and a *Rose-bush* being milkewed. In consequence of Ferns being in the house I could not burn sulphur. Will someone give me full advice how to get rid of it so as to eradicate the dreadful pest? Last year I lost about a hundred bunches of *Grapes*, in spite of sulphur-dusting, &c.—AMATEUR.

5680.—**Climatis indivia.**—I have one of the above-named climbers growing in a pot, which I thought of planting in a large tub, and placing at a corner of the stage in a greenhouse. Would it do so well by the tub underneath the stage; also when would be the right time to replant? It is in full flower now. It is very much subject to a kind of brown-scan. How can I get rid of the pest? It is such a tedious process to wash each leaf, and it soon returns. Syringing is advised with some preparation. Ought the Ferns, &c., standing underneath to be removed for the time being?—S. A. B.

5681.—**Bed for Cucumbers in a frame.**—I should be much obliged if someone would inform me, in telling me what is next issue, whether my gardener is right in telling me that it is impossible to make up a bed for Cucumbers in a frame at this time of year with Moss-litter? I have no straw-manure, but plenty of Moss-litter and an unlimited quantity of Oak-leaves. And if possible, state precisely how to proceed? He says no bed can be made thus which will keep its heat above 50 degs. It is true that the Moss-manure seems damp and cold. Are any precautions in keeping it necessary?—BURLINGTON.

5682.—**Yellow-barked Willow.**—In *GARDENING* issue, Feb. 17th, is mentioned *Salix vitellina* as the "Yellow-barked Willow." My attention was attracted to this tree in the wood of a Willow blown down during the recent storm. Underlying the bark was a ring about 1/2 inch in width of soft, spongy tissue, which, under pressure, exuded yellow juice. Will "A. H." kindly state whether this is the ordinary colour of the rising sap, or was *S. vitellina*? I may mention that the bark showed no signs of yellow colouring, being quite black, but that, of course, was owing to the smoky atmosphere of our city.—M. A. HAWKINS.

5683.—**Cacti eaten by moom.**—Having lately had two *apelmurus*—viz., *Echinopsis multiplex* and *Echinopsis texensis*—destroyed by these mischievous little animals, I shall be glad to know whether any of your readers have been troubled with the same? The *Echinopsis* grows through larger than a good-sized cricket-ball, which I have used in my Green-house for five or six years, and was nearly eaten out in one corner by their burrowing into the soil beneath the plants, the hard leather skins and dense species protecting it from outside ravages. I purpose drying the shell, as it were, dusting with charcoal powder, and re-potting.—W. N. G. LANCE.

5684.—**Roses all this year round.**—I wish to thank "J. C. C." and "P. U." for valuable advice in *GARDENING* for April 8th, 1893, and shall be glad if they will now assist me further. My first batch of Roses under glass flowered freely until the middle of January. What can I do with them now that the second batch has come to take their place? If they go into any other greenhouse they must share the fate of the other plants here as regards ventilation. Will that not cause mildew? Must they now continue to have liquid-manure, or plain water? Must the weak wood be cut out now, or when? If they show a tendency to grow in the summer are they to be allowed to do so?—ADAM.

5685.—**Brick pits.**—I am proposing to build five brick pits in a row across the central part of my garden. They are to replace some worn-out wooden frames. I shall be grateful for full advice and directions how to proceed? I would like to know how to lay the front and back

walls should be (1) from foundation to top, (2) from surface of ground to top, and whether ordinary mortar should be used, and how the wood framing necessary for the sashes to stay in place can be done. Also I am anxious to know whether hot-water pipes and a stove or stovish-unit would be cheapest and best? If the former, what is the best system of pipes and boilers, what should be the diameter of the pipes, how many are necessary, and where and how should they be fixed? Is the earth filled in over them?—AMATEUR.

5686.—A "striking" pit in a greenhouse.—Will "B. C. R." kindly give me advice on the following? I am about to make a "striking" pit in the corner of my new greenhouse next to boiler, which is an upright cylindrical one. The pit will be 4 feet 6 inches long, by 2 feet 8 inches wide, and the bottom will be formed of strong perforated zinc, and standing 2 inches above 4-inch hot-water pipes. Inside of pit will be about 6 inches of Coco-nut-fibre for planting, &c. Under the pit only I propose having at each end a three-way 4-inch syphon, and three 3-foot lengths of pipe running side by side in flow-pipe, only the return will be simply a single 4-inch pipe, so really under the pit I shall have four pipes. Will it be necessary to have these pipes to get sufficient bottom-heat for ordinary market purposes? And will it be necessary to entirely enclose the pipes in the pit, or is the above suggestion correct?—D. WILKES.

5687.—Grub-eaten Pansies and Carnations.—I should be obliged if someone will advise me in the following matter. In the past winter I had a number of Pansies and a few Carnations destroyed by a small grub eating the stems just above the ground. The grub is about half an inch long, one-sixteenth of an inch thick, and greyish-white in colour. I have caught hundreds of them with Potato and Carrot baits, as advised in GARDENING, so often, but they multiply so fast it seems almost impossible to get rid of them. There is also another insect among the manure in an old hot-bed. It is about two inches long, one-sixteenth of an inch in thickness, yellow in colour, with larvae in it. This pest is very full of worms, but am not sure. It certainly eats the roots of the Pansy, for I caught one last summer at the root of one plant which died. If anyone can help me I shall be grateful. My beds are now clear, and have been dug over repeatedly this winter and dressed with lime.—BIRROX.

5688.—Marchal Niel Rose.—I should be glad to know whether "J. L." (page 689), grows other plants in his house with the above Rose? Also by "old-house," does he mean a house without any heat whatever? I have had a M. N. Rose in a pot three years; last spring I cut over 40 blooms, some fine, others poor, and I thought it bad done well. It is looking very healthy now, and buds are forming at every joint. This pot is very full of roots, and I thought I would plant it out in the same way as "J. L." When should it be planted? Also when should it have the new flowering branches pruned? The temperature of my greenhouse is kept at about 55 degs., and I have a mixed collection of plants. I syringe the Roses and Lilies every day, and occasionally wash every leaf and branch with a mixture of Quassia and soft-soap, but a few days after there will be green-fly again in great numbers. An old tree of thistle in the garden, on the back trellis, I find especially troublesome. I take air from a top ventilator and one or two from others every fine day.—S. A. B.

5689.—Tomatoes in a greenhouse.—I am going to make a greenhouse 12 by 9 for growing Tomatoes. Will anyone who has sold me an ink be able to tell me if a masonry house in the following way is for high, 3 feet of glass each side (it being span-roof), and being able to get plenty of old railway sleepers, these being 6 inches, it will bring it up to 4 feet 6 inches to eaves? I am going to stand the house on sleepers. These I thought would form shades of trough. I shall have one trough each side 18 inches by 18 inches, and one in centre of house 2 feet wide. This will give me a pathway of 2 feet round the house. I purpose to have one row of Tomatoes round the house to trap up the heat, and one in centre of 2 feet to train Tomatoes up centre of roof. I am going to plant 1500 plants. Will someone kindly state number of plants I can grow in the above-size house, and shall I put mould on the earth, or would it be better in troughs? There will be a good portion of glass. I shall be thankful if anyone will kindly let me know if I am doing right?—T. Y. R. R. READER.

5690.—A small garden, &c.—I should be much obliged if someone would kindly advise me how to make the best of a little garden at the back of my house, which is a mere strip of rough tiring ground, 90 feet by 21 feet, soil sandy and gravelly, facing north, and with fields beyond. Leading up from this garden by a wall there is a 3-foot-wide bed under my dining-room window. What should I look best there? On three parts of this no one reaches. Is there any small-sized grass mowing machine that will adapt itself to such uneven ground which I could use for myself? I have one of Ransome's, with 13-inch knives, but it is much too heavy for my use. The landlord will not do anything in the garden, so I do not care to spend much over it myself, only what the culture of the flowers require. It is surrounded by a park paling, round which last summer we had a narrow bed out, and had some annuals and bedding-plants, with Kidney Beans on the paling behind. Will Polyanthuses grow well on this soil? Please say also what kind of water-hose, roses, &c., would be light enough for a lady to water the garden for herself? There is plenty of tap-water. In the corner of my dining-room I have an "Elk's-horn Fern," growing on a piece of cork hung on the wall. It has flourished well the last five or six years, but now most of its leaves have died off. What is amiss? I dip it in water twice a week, about. My Aralia leaves are turning yellow. It is not over-watered, is well drained, and we use no gas in this room. Does it want a larger pot?—CHICKEN.

To the following queries brief editorial replies are given; but readers are invited to give further answers should they be able to offer additional advice on the various subjects.

5691.—An Orchid for a cold greenhouse (Pitcher).—I know of no species of this family that would succeed in such a place, having the hardy terrestrial kind, and they would thrive better in the open air. —M. B.

5692.—A Pitcher plant for a cold greenhouse (Pitcher).—None but the North-American Pitchers would succeed, and these would grow finer if raised in some warm pit. There is now a great many kinds. You may obtain plants of these Sarracenias from any of the London nurseries.—J. J.

5693.—Lycopodium cruentum. G. asks what species this is, of which he sends a flower? From your note I take it to be cruentum, but I have had it marked aromatica for several years. Yes, you are quite correct; the true aromatica is without the blackish-purple spot in the lip, and it is not nearly so large a flower.—M. B.

5694.—Cola Nut (G. Berrie).—This plant is a native of West Africa. It forms a tree of 40 feet to 50 feet in height. The natives do a large trade in the seeds of the Bitter Kola, or Cola. The seeds of another kind are used for rendering purged water sweet and agreeable to the taste. It is called Sterculia acuminata.—J. J.

5695.—Dendrobium Devonianum (J. H. R.).—This is a very deep-coloured flower of the species, and the lip is most deeply tinged thus usual. I would advise you to look well after this plant, and take care of it. I cannot but think that you have kept it very warm, as it is flowering, at any rate, about two months before its time.—M. B.

5696.—Plant to grow in water (Pitcher).—I should advise you to use the common Reed (Arundo phragmites), which grows upwards of 6 feet high, and bears a handsome panicle of flower on the top, to which you might add the plant popularly, but erroneously, known as the "Bullrush" (Typha latifolia). Gold fish will live with these.—J. J.

5697.—Dendrobium Wardianum. B. J. B. sends me some very nice-coloured flowers of this species, which appear to me almost like the flowers of the Assam kind. Perhaps he will tell me, if he knows, if this plant comes from Assam or Borneo? They are very neat and brightly-coloured flowers, and, from the quantity you have, they have been done very well.—M. B.

5698.—A propagator.—Do not stop the seals in the Coco-nut fibre, but in boxes, pans, or pots of suitable soil, which are to be put in or laid on the warm fire. An inch between the top of chimney and bottom of the evaporating pan is hardly enough, and is apt to cause the lamp to smoke if turned at all high; 4 inches is better or 2 inches for a large affair.—B. C. R.

5699.—Dendrobium crassinode. S. B. sends a nice gathering in variety of these flowers, and I am very sorry to say that after his kindness in doing so that I cannot select one and say it is a good dark-coloured flower, but all are commonplace varieties. The one with some D. Wardianum hood in it I had entirely to see, and I think you cannot have put it in with the other hoods.—M. B.

5700.—Dendrobium Devonianum (A. Fox).—You may sow this seed, which you have imported, upon the Sphagnum in a basket, which is hung up from the roof, having some plant of Dendrobium in it, but I do not think you will meet with much success. The small shoots are perhaps seedling Orchids, and should be planted in a small basket and kept growing. Am glad to hear your Orchids are promising well for flower.—M. B.

5701.—Orchids flowering in or about August (F. R. H. S.).—Some kinds of Aechmes, Barkerias, Calanthes, Celydons, Celogyas, Corymbes, Falsatuses, Helyconias, Epidendrum, Grammatophyllum, Leptis, Masrivalvia, Odontoglossum, Oncidium, Saccolabium, Stanhopea, Stanhopeas, Vandas, and others. I fear your question is far too open for the answer to be of much service to you. You had better reduce it to what you really require, so that I can give you some useful information. Try again.—M. B.

5702.—Evergreen Ferns for a cold-house.—S. M. writes for the names of some Ferns which would succeed in a cold greenhouse, by which I suppose she means one that is not heated at all, and the following I have selected as being suitable. One or two might fail, but I do not think many would; Adiantum formosum, Asplenium Adiantum-nigrum, Asplenium marinum, Cyrtidium latatum, Cyrtidium caryotoides, Laetia Sieboldii, Lomaria alpina, Niphobolus lingua, Niphobolus lingua corymbifera, Platyloma rotundifolia, Polystichum Lonchitis, Neolopendium in variety, Todea hymenophylloides, and Todea superba.—J. J.

5703.—Maiden-hair Ferns (William Fisher).—I really do not know how to advise, for you appear to desire to do a lot without the slightest convenience. To ensure success you might, and probably could, grow them in the summer season, but do not think you would be successful in the winter; but you can try them. You should fill up your bed some 2 feet with crocks, and above this place the soil, to consist of about equal parts of loam and peat, made fairly sandy. I should think the sand you mention as being handy would answer very well, but you might wash it well before using. The best kind for you to grow would be Adiantum cuneatum.—J. J.

5704.—Catasetum and Mormodes (J. Perry).—These are the plants I should think from the description which you have received from your friends in tropical America. They should at once be potted in peat fibre and Sphagnum Moss. They should be well trained; the plants gathered above the plants should be kept in a very superior moisture; they should be freely exposed to the light, and set upon a side stage at the warm end of the Cattleya-house or East Indian-house, and water must not be given overhead until the plants are well rooted and the growth about half formed. From these plants some new varieties and many deviations in form may occur, and I should like to hear from my friend again when the plants flower.—M. B.

5705.—Plants from Birmah.—North Rose sends a very long letter in which he asks many questions, but I cannot answer many of them definitely, but must see specimens first. I cannot make anything at the sketch, but he will find all his wants supplied by getting the new edition of "Williams' Orchard Manual," now publishing. The old growth of Dendrobium Wardianum should be pegged down upon some soil, and the young ones would root into it. I am afraid you have been keeping them too hot and too wet, and what would otherwise have been flowers has proved to be growth only. D. Dalhousianum should have flower every season if you rested it well. I would not trouble to disturb it, but give some fresh soil

now at once. Yes, it likes the sun, and should be syring up from their rest now; at this season they require the hottest place you can give them. The Cattleya appears to have done well, and you can only keep on with this in the same way. You could not have expected the old hills to break so strongly as the leading shoot. Your many wants will be answered by the book noted above. Shall be very glad to receive your specimens; will give you the correct names, if possible.—M. B.

NAMES OF PLANTS AND FRUITS.

*. Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, W.C.

Naming fruit.—Readers who desire our help in naming fruit must bear in mind that several specimens of different stages of colour and size of the same kind greatly assist in its determination. We can only undertake to name four varieties at a time, and these only when the above directions are observed. Speedy parcels will be acknowledged. Any communication respecting plants or fruits should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 37, Southampton-street, Strand, London, W.C.

Names of plants.—Constant Reader, Dringale, Canada.—1, Begonia Ingrandi; 2, Begonia Fuchsoides; 3, Begonia metallica; 4, Sparmannia africana.—A. Inverness.—Acacia armata, a very pretty greenhouse-plant. The treatment seems to have been all right.—Bennetton.—Epidendrum ciliare.—C. May.—Odontoglossum Rossi majus.—S. M.—1, Pteris tremula; 2, Asplenium sp., send better specimen; 3, Polypodium vulgare; 4, Selaginella hortensis; 5, Selaginella, send better specimen.—St. Ambrose.—I cannot tell for certain from your specimen. I should think it was a Jasmium. Send more information.—G. Russell.—1, Dactylis atricium; 2, Lomaria maculata; 3, Asplenium fuscilobum; 4, Cyrtidium Fortunei.—J. P.—1, Notochloa lamuginosa; 2, Barallia pyxidata; 3, Platycerium alboborne.—John Kemp.—1, Pontederica; 2, Impatiens Sultanii; 3, Franciscia alycaulia; 4, Eranthis pulchellum.—Herrie.—Dendrobium Answorthii; Lilia kempiana; 3, Lycostelea; 4, Sophronitis grandiflora; 5, Sophronitis cernua.—J. P.—1, Phlebotium aureum; 2, Dithyria attenuata; 3, Selaginella erythrospora; 4, Pteris Kingiana; 5, Polystichum dentifolium; 6, Hemistictis adiantoides.—A. Dean.—1, Cattleya Purcelliana; 2, Lilia anceps Scottiana; 3, Lilia anceps Willinkii.—H. Wallace.—Sporophylla africana.—K. S. M., Witley.—An iris apparently, but flower was so spoiled by being in dry cotton-wool, that we cannot give its proper name. Please send again, and do not pack in wool, wrap in white tissue paper.

TO CORRESPONDENTS.

We should be glad if readers would remember that we do not answer queries by post, and that we cannot undertake to forward letters to correspondents, or insert queries that do not contain the name and address of sender.

Constant Reader, Balsover.—Apply to Messrs. Geo. Bunyard and Co., Maidstone, Kent.—Frank Gordon.—Apply to Mr. T. B. Ware, Hale Farm Nurseries, Tottenham, London, N.—T. W.—It is not very unusual for a flower of Calla thalictroides to open as described. The plant is in good health, and should certainly be kept for another season.

Catalogues received.—Hunting Apparatus, &c.—Messrs. Chas. Toope and Sons, Stoney-square, Stoney, London, N.—Habitat, Dahlys, Vegetable and Flower Seeds, &c.—Messrs. Ault, Rozen and Son, Overreen, near Harlow, Herts.—Farm Seeds.—Messrs. Hickensoy, Chester.—Fuchsia's, Fuchsia, Clematis, &c., and Perennials.—Mr. T. B. Ware, Hale Farm Nurseries, Tottenham, London, N.—Phlox's Flowers and Hardy Border Plants.—Mr. John Forbes, Hawick, Scotland.

BIRDS.

5467.—Management of a Parrot.—Give Canary-seed and Millet, and sometimes a little Hemp. Never give meat, as they are not carnivorous. A piece of sliced and small fruits, when in season, and other seeds and Grains are also in season. Fruit-berries, Arbutus, and Black-berries, when in season, make a change.—E. M. H.

Robins building.—In reply to "J. H.," the time of nesting varies a little, according to whether the spring comes early or late; but the regular season is from March to July, May and June being the months in which most nests may be found. They do not build in shrubs, but their favourite site is a hole on some wild bank sloping down from the side of a wood into a road or lane. The natural food of the Robin consists of worms, insects in all their stages, seeds, berries, and small fruits, such as Cherries and Currants. Boiled Potato, egg, and bread suit them.—B.

"Gardening Illustrated" Monthly Parts.—Price 6d., post free. "The Garden" Monthly Parts.—This journal is published in weekly bound Monthly Parts. In this form the coloured plates are best preserved, and it is most suitable for reference previous to the issue of the half-yearly volumes. Price 1s. 6d.; post free, 1s. 9d. Complete set of volumes of this GARDEN from its commencement to the end of 1893, forty-two vols., price, cloth, 43s. 12s. "Farm and Home" Monthly Parts.—This journal is published in weekly bound Monthly Parts, in which form it is most suitable for reference previous to the issue of the yearly volumes. Price 5d.; post free, 6d. "Hardy Flowers."—Giving descriptions of upwards of thirteen hundred of the most ornamental species, with directions for their arrangement, culture, &c. First and Popular Editions, 1s.; post free, 1s. 3d. London, 37, Southampton-street, Strand, W.C.

BEES.

SEASONABLE NOTES.

The Snowdrops and Crocuses now making their appearance will tempt the Bees abroad on mild days in search of pollen, and the Bee-keeper will be reminded that he should begin to make preparation for the coming season by providing himself with the necessary number of hives, sections, supers, feeders, comb foundation, and other appliances. The Bees may be greatly assisted in pollen gathering if Pea-meal be sprinkled upon the Crocus blooms in fine weather. It will be collected and stored in the hive, and will save the Bees the risk of travelling far in search of natural pollen. Rye or Wheat meal will answer the same purpose, and may be placed in skeps or boxes in sunny corners; some wood shavings laid upon the meal will afford the Bees a foothold while collecting it, and a piece of honey-comb laid upon the shavings will quickly guide the Bees to the spot.

STORES ON HAND.—Colonies properly provisioned in the autumn should not require feeding at present, but if feeding is found to be necessary to prevent starvation, the food should be supplied on a mild evening, and only as much given as the Bees can take in a few hours, so that the excitement caused by the feeding may subside before morning. If feeding take place in the day-time, many Bees will be tempted to fly abroad in search of natural stores, and may never regain their hives. A good feeding syrup may be made as follows: To 3 lb. of boiling water gradually add 10 lb. of granulated sugar, keeping it stirred with a wooden spoon till all the sugar be dissolved, then add half a teacupful of water in which has been dissolved a teaspoon, level full, of tartaric acid, when, after stirring a moment longer, remove from the fire. This syrup, when cool, is of the consistency of ripe honey, and the tartaric acid prevents it becoming candied. It should be supplied, just warm, in a feeder placed on the top of the hive, the whole being well covered with some good heat-retaining material. Another very good food is made by mixing liquid honey and finely-powdered loaf sugar together to the consistency of putty. This can be laid upon the frames in the form of a eske, and is readily taken by the Bees. By this manner of feeding no disturbance is caused to the colonies.

WATER-TROUGHS.—During the spring months strong colonies require a constant supply of water, which is used with honey and pollen in the rearing of the brood. If water be found near home, much Bee-life is saved, since many Bees perish while searching for it in ditches and ponds during the prevalence of cold winds; it is, therefore, wise to supply water in shallow troughs near the hives; stones should be placed in the water for the Bees to alight upon, and the troughs be filled up, as required, with clean water in which a little salt has been dissolved. A change of floor-boards is advantageous as spring advances and the Bees begin to work. The hive can be raised from the board by gently pushing wedges beneath, allowing it to remain for a few minutes until the Bees are quiet, when it may be placed on a clean, dry floor-board upon its former stand. All causes

of dampness must be removed as soon as discovered. The chippings of the combs, dead Bees, and other rubbish which collects on the floor-board sometimes becomes damp and moldy. When the hive sides rest upon the floor-board, dampness often draws in, and spreads over the hives; this may, however, be obviated by having the hive sides made to fit outside the floor-board. The coverings of straw skeps should be sufficiently large to throw off the rain quite clear of the floor-board.

COMB PASSAGES.—If there are no holes in the combs to enable the Bees to pass through and reach their stores in the combs adjoining the cluster, it necessitates their going round the ends of the frames, which causes them to become chilled in cold weather. These passage holes can be formed for the Bees by passing a narrow-bladed knife through each comb near the top, or a little instrument called a passage cutter may be used; it is a tin tube, having the edges serrated like a saw, and a wooden plunger works inside it. The edge is passed through the comb, with a circular motion, and on withdrawing it, the piece removed from the comb is driven out of the tube by the wooden plunger. This handy little affair may be obtained of any dealer in Bee-keeping appliances. When candy is given over the frames under the quilt, these winter passages are unnecessary, as the space the candy occupies gives the Bees an opportunity to pass over the tops of the frames in order to reach their stores. S. S. G., *Sturminster, Newton.*

QUERY.

6700.—**Book on Bees.**—Will some reader recommend an inexpensive but good book upon Bee-keeping?—*DUNNOTTAR.*

POULTRY AND RABBITS.

5460. — **Poultry-keeping.** — "Scotch Farmer" deserves credit for stating his query so well. I will try to give him a reply which shall be equally satisfactory. I consider it possible for him to improve his birds without going to much expense; but before I attempt to explain how this is to be done, it may be as well to reply to the various points he has raised. It appears that he sells about 120 chickens for table purposes every year. This clearly proves that he must keep table properties in view when he arranges his breeding plans for the season. Dorkings and Minorcas may both be expected to lay freely during the spring and summer; but I should not look for many eggs, as a rule, during the cold weather from either breed. The feeding arrangements are not good—bran, Potatoes, and Turnips can never be considered good foods, although Potatoes are admissible in cold weather. Barley-meal should be mixed with the sharps during the winter, and a little may be used at other seasons in order to make the sharps adhere, unless ground Oats are used. I prefer some of the specially-prepared poultry foods in addition to sharps for the morning meal. For the afternoon feed, I am certainly not a believer in light corn of any kind, but should use sound Wheat, Buckwheat, or Barley, or heavy Oats for a change. The Houdan cock makes a good cross for table purposes, and some

strains are excellent layers, but Houdans do not sit, and thus they introduce a non-sitting element wherever they are used. The Brahma cock produces larger-framed chickens, and good winter layers, but the best class of customer will not care for the chickens on account of their size. Indian Game cross well with the Dorking for table purposes; indeed, this is the best cross which can be mentioned, if there is a best; but the laying properties are deteriorated rather than improved, hence the querist will injure his prospects if he depends upon this. The Wyandottes are not all alike; some are excellent layers of large eggs, others are indifferent layers and produce small eggs. They cannot be classed amongst the best table fowls, so that "Scotch Farmer" need not seek further in this direction. Having now touched upon the several points raised in the query, I propose to give "Scotch Farmer" the best advice I can. He must remember first of all that winter layers are the most profitable birds he can hope to get; he should therefore lay himself out to secure as many of them as possible. My experience has been that a cross-bred bird is likely to answer most in this direction, and the cross should be made between sitting and non-sitting breeds. The feather-legged breeds will supply the former, while amongst the non-sitters I should take the Leghorn, Anlalusian, and Minorca breeds to select from. The heavy breed will supply a brown-tinted shell; the other will bring in the laying properties. Brahmans, Cochins, Plymouth Rocks, or Langshaus can be specially mentioned as likely to supply suitable hens, and I should choose the Leghorn cock. From fifteen Leghorn-Brahma pullets I have an average about 54 eggs from October 1st to January 31st of the present winter. The birds are handsome to look at; they are good foragers, they sit well, and the cockerels make acceptable table fowls in June and July when chickens are scarce. This is the cross I should recommend "Scotch Farmer" to go in for. Let him buy half-a-dozen Brahma pullets of 1893, and a Leghorn cock of 1892; put them in a separate run, and use the whole of their eggs for sitting. Hatch the chickens as early as possible, and be careful not to sell the pullets. For table purposes I should breed on different lines. Take the Dorking hens, as the querist proposes, and mate them with an Indian Gamecock. Chickens thus bred are simply superb, large shouldered, broad-breasted, weighty birds, which will satisfy the most fastidious customer. The pullets, however, must not be kept for stock. In conclusion, I would remind "Scotch Farmer" that winter layers must be hatched in March if at all. Such birds come to lay early in the autumn, and continue to do so throughout the winter. A May pullet may not lay a single day earlier than another hatched in August, and thus proves a dead loss from the first. Another mistake which tells much against farmer's poultry is the indifference with which stock birds are selected. I believe in first crosses or pure breeds, the former for choice, but I would never attempt to breed beyond the first cross so far as laying stock is concerned.—*DOULTING.*
